

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

CHEMICAL ABSTRACTS

Vol. 9.

JUNE 10, 1915.

No. 11.

I. APPARATUS.

L. C. JONES.

Some notes on easy and accurate work with pipets. GEORG TH. PANOPULOS. Berlin. *Chem. Ztg.* 39, 248(1915).—Manipulation of graduated pipets is made easier by attaching a short piece of soft rubber tubing to the top, a short piece of glass tubing being in the other end of the rubber and a glass ball between. By squeezing the tubing at the ball air is admitted and the flow regulated.

J. H. MOORE.

Modified Jannasch bromine apparatus. V. ZARVNY. *Z. anal. Chem.* 54, 159-61 (1915); see fig.—All connections, except last, are of ground glass. Three Fresenius flasks are used for evolution of the Br₂ for the O-HCl gas. App. was devised for use in the analysis of tetrahedrite and arsenopyrite.

F. W. SMITHER.

A new aspirator. HENRI VIGREUX. *Bull. soc. chim.* 17, 41-3(1915).—The app. described is already in quite common use but has one modification. Air under moderate pressure for blast lamp work, etc., may be obtained by passing the discharge from a filter pump into a Wolff bottle from which the outflow may be regulated by a pinch cock. A screw set in the side of the pump may be advanced into the direct stream of water where it enters the air chamber inside the pump to spread the stream and cause it to carry more air. By regulating the screw the app. may be adjusted to various water pressures. It is claimed that the app. will give 600 liters of air per hr. at a pressure of 9 cm. Hg with water pressure of 28 m. The app. may be obtained from M. Leune, 28bis rue Cardinal-Lemoine, Paris. F. A. HARVEY.

The tapalog, a new multiple record pyrometer recorder. ANON. *Mel. Chem. Eng.* 13, 260-1(1915).—A multi-colored typewriter ribbon distinguishes between the different couples connected to the instrument. The record is 5 1/4 in. wide and advances 1 in. per hr. The paper used is suitable for blueprinting. Advantages claimed are ease of renewing paper and of changing the number of records taken at one time; rectilinear coördinates; points recorded every 12 sec.; slight mechanical work for the clock, dust-proof construction, and Pt-Rh elec. contacts throughout. Also in *Elec. World* 65, 871(1915).

W. L. BADGER.

Explanation of the calculation of the thickness of the walls of cylindrical copper steam and pressure vessels with internal over-pressure. ERNST GOLZ. *Chem. App.* 2, 73-5(1915).—A discussion of the formula, with quotations from official rulings.

J. H. MOORE.

Tests of vacuum pumps. P. Q. WILLIAMS. *Practical Eng.* 19, 390(1915).

C. G. F.

A brief history of the thermometer. W. S. ATCHISON. *Power* 41, 575(1915).

C. G. F.

A new hydrometer of total immersion with electromagnetic compensation. ANDERS ANGSTRÖM. Borno Station, Sweden. *Phys. Rev.* 5, 249-52(1915).—The app. consists of a glass tube, about 4 cm. in diam., with a coil of wire about 12 cm. long

wound around its lower half. The tube is constricted to a stopcock at the bottom. The float is drawn out into a narrow tube that contains a rod of soft iron 4 cm. long and 2 mm. in diam. The float is counterbalanced and held to the limiting point by means of Pt spirals of known wt. and then the current in the coil increased until the float is pulled down to a definite distance from the coil. This position is one of stable equil. provided the float is not brought too close to the coil. The most sensitive position occurs just before unstable equil. is reached. Marks etched on the tube and float show the proper position. Calibration is effected by filling the tube with liquids of known sp. gr., making a rough adjustment with the Pt spirals, and fine adjustment with current in the coil. The app. has been used to det. sp. gr. of sea water. With the aid of a current between 0 and 75 milliamperes the range of variation of the soln. which may be detd. by the current was about 2 per mil. The mean deviation of a set of observations was less than 0.01% of salinity.

F. A. HARVEY.

New crystal-grinding goniometer. F. E. WRIGHT. *J. Wash. Acad.* 5, 35-41 (1913).—Details are given of a new grinding goniometer with which crystal faces can be ground with a precision of 1' or greater, and flat within a wave length of light; plane-parallel crystal plates can also be ground normal to any given optical direction, as an ellipsoidal axis (α , β , or γ) or an optic axis. The instrument is based on the theodolite principle, but it is essentially different in design and construction from earlier types; certain features of the Goldschmidt design have, however, been incorporated in it.

F. W. SMITHER.

U. S., 1,135,002, Apr. 13. G. M. ELLIS. **Acetylene generator.**

U. S., 1,136,108, Apr. 20. R. W. CURTIS. **Buret with a glass stopcock and an adjustable stop for regulating the maximum opening of the stopcock.**

U. S., 1,136,227, Apr. 20. L. GOLDBERG. **Apparatus for generating ozone.**

Brit., 28,345, Dec. 9, 1913. I. HALL. **Construction of a device for agitating and mixing molten material in melting furnaces.** Cf. *C. A.* 9, 594.

Brit., 28,496, Dec. 10, 1913. L. V. MASONI. **A protective jacket and safety discharge fittings for storage receptacles for inflammable liquids.**

Brit., 28,609, Dec. 11, 1913. R. FRIGNOUX. **A phial for serum and like substances** comprizes a sealed tube *a* drawn out at the ends to form finely bored extensions *b*, and *c*, the end *c* being bent to lie along the side of the tube. In use, both ends are nipped off, and the needle of an hypodermic syringe inserted in the end *c*. The bore of the part *c* is so fine as to prevent air hubbles from passing in the reverse direction as the contents are drawn off.

Brit., 28,988, Dec. 16, 1913. W. J. COOPER. **An oxy-acetylene, oxy-hydrogen, or like burner for welding, cutting, or for search-light purposes,** comprizes a rotatable plug valve, for simultaneously controlling both gas supplies, which is provided with a mixing passage, an axial exit passage and transverse inlet passages adapted to communicate with the transverse supply passages in the plug socket for O and C_2H_2 , etc.

Brit., 29,094, Dec. 17, 1913. H. R. WEBSTER. **In gas-testing apparatus** working on the diffusion principle, the indicating or recording parts are mounted in a frame or casing, which can be moved towards or away from the pressure-recording diaphragm of the diffusion chamber, so as to adjust the indicating or recording part to zero. Cf. *C. A.* 9, 1242.

Brit., 29,184, Dec. 18, 1913. W. REID. An arrangement for clarifying liquids containing suspended matter, such as H_2O containing coal dust, comprizes a series of open troughs of inverted triangular section, within each of which a vertical or substantially vertical partition extends from above the top of the trough downwards, a space being left between its lower edge and the bottom of the trough. The troughs are assembled side by side with their abutting edges making joints and with partitions closing their ends and extending above their level. A wide shallow stream of the liquid enters from a launder, and the deposit is fed by worm conveyors in the troughs to an endless band discharging over a lip on an inclined part. The worm shafts pass unpacked through an inner wall and carry sprocket-wheels for a driving-chain within a recess. Alternatively, worm conveyers in the troughs may push the material directly into the inclined exit with or without the addition of an inclined worm conveyer; or a series of parallel band conveyers may be used instead of the worms. A suction pipe or other means may also be used for removing the deposit.

Ger., 280,968, Sept. 25, 1913. SOC. ANON. POUR L'IND. CHIM. A BAIE. Furnace for producing pure carbon monoxide from O and C, comprizing a centrally placed, narrow

H_2O -cooled Fe nozzle *d* for introducing O into a H_2O -cooled furnace which is charged with coal. Fig. 1 shows the furnace in cross-section. Fig. 2 is an enlarged cross-section of *d*. In Fig. 1, *a* is the Fe casing of the generator, *b* the water-jacket around the lower portion, and *f* is the bottom plate, composed of an Fe plate covered with fire-brick. This bottom plate may be double-walled and H_2O -cooled, or *d* may be lengthened and the bottom plate single-walled. The gas generated escapes through the tube *h*. Through the double-valve charging device *i* the carbonaceous material may be charged during the operation. The base of the furnace is constructed to permit removal of *f*. The O is fed to the nozzle (Fig. 2) through the tube, and through the narrow opening of the removable cap 4 into the furnace. The cooling tube 2 terminates directly under 4. Cooling H_2O enters at 5 and passes, as indicated by arrows, through the nozzle and out at 6 from the tube 3.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Wilhelm Hittorf. ALFRED CORHN. *Naturwissenschaften* 3, 41-3(1915).—Bio-graphical. C. G. F.

W. Sackur. ANON. *Elektrotechn. Z.* 36, 11(1915).—Died Dec. 17, 1914.

C. G. F.

Theory of chemical reaction and reactivity. E. C. C. BALY. Univ. Liverpool. *J. Am. Chem. Soc.* 37, 979-93(1915).—When 2 atoms approach one another sufficiently closely, the force lines due to their respective fields will condense with loss of energy,

establishing a potential gradient. If this gradient be sufficiently steep, a transfer of one or more electrons will take place, and a true chem. compd. will be formed. The general stability of the compd. will depend upon the condensed force field between the atoms of which it is composed. If the fields of 2 mols. are of opposite types, the force lines of the two will condense, with the formation of an addition compd., perhaps followed by the formation of a true chem. compd. by the exchange of electrons if the gradient is sharp enough. Thus HX and YOH (un-ionized) may unite to form HX.-YOH, then rearrange to XY.H₂O, a system contg. less energy than the system HX.-YOH. If the force lines of 2 mols. form completely closed systems, no reaction will occur between them until the fields are opened up, as for example, by the mols. of a solvent. HCl and NH₃ form closed systems, and so do not react until the fields are opened by H₂O. H₂O possesses a "balance of uncompensated force lines," which accounts for its power of forming hydrates and addition compds. Aq. solns. of Hg(CN)₂ and KI are each diactinic to all rays of light above $1/\lambda = 5000$; therefore their absorption bands lie at shorter wave lengths. A moist mixt. of the 2 salts was exposed to light from a H vacuum tube through a fluorite window, and HgI₂ was formed in small amts. at the points where the light fell. This furnishes evidence that an equil. has been set up between the opened and unopened fields in the dissolved mols. The selective absorption increases the number of "opened" mols., and shifts the equil. to the reactive side. Allotropy, magnetic rotation, stereoisomerism, etc., are mentioned.

E. B. MILLARD.

Atoms and ions. J. J. THOMSON. *Engineering* 99, 251-2, 277-8, 303-4(1915).—The presence of ions in air was shown by means of a Zeleny electroscope. A lighted match caused the electroscope to discharge. Air blown over Po, Röntgen radiation, ultraviolet light, Schumann light, and the radiations from hot metals also produced ions in gases. Light which passed through a fluorite window into a discharge tube was capable of ionizing the gas within it, but a quartz plate stopped the passage of the ionizing rays. Hg vapor required an amt. of energy for ionization equiv. to 4.9 v., N 7.5 v., and O 9 v.; the inert gases were more difficult to ionize. A wave length of 2536 Å. should ionize Hg, but to ionize N the light must be shorter than 1600. Quartz is opaque to such short waves, but fluorite may be used for waves as short as 1200. The formation of ions by splashing was discussed. It was not possible to say whether or not ionization was ever produced by chem action. The electrification of H produced from HCl and Zn was possibly caused by the bubbling of the gas through the H₂O, since no electrified H was produced from Zn powder and gaseous HCl. The oxidation of NO by air gave rise to no ions, as shown by directing the stream of NO on the electroscope terminals. Tubes contg. Rb or Na-K alloy liberate electricity under the action of light. It was calcd. that at 2000° 1 particle in every 74000 of gas should be ionized, and at 0° only 1 in 10²⁸, i. e., a single ion per liter of gas. E. B. MILLARD.

Revision of the atomic weight of lead. Analysis of lead bromide. G. P. BAXTER AND T. THORVALDSON. *J. Am. Chem. Soc.* 37, 1020-7(1915); see C. A. 9, 984.

E. B. MILLARD.

Revision of the atomic weight of lead. Analysis of lead bromide and chloride. G. P. BAXTER AND F. L. GROVER. *J. Am. Chem. Soc.* 37, 1027-61(1915); see C. A. 9, 984.

E. B. MILLARD.

The atomic weight of copper by electrolysis. ALBERT G. SHRIMPTON. Paddington Tech. Inst. *Proc. Phys. Soc. London* 26, 292-312(1914).—Four Cu and 2 Ag voltameters were operated in series. The areas of the 4 Cu cathodes varied from 10 to 50 sq. cm. To eliminate the loss in wt. by soln., the wts. of the Cu deposits were plotted against corresponding cathode areas and the corrected wt. was obtained by extrapolating this curve to zero area. The at. wt. of Cu = (107.88' × 2 × corrected

wt. Cu)/(mean wt. Ag). Mean of 10 detns. = 63.563 ± 0.003 mean error. Several points are noted in regard to obtaining coherent deposits, and in regard to proper current densities.

PAUL D. FOOTE.

Theory and use of the molecular gage. SAUL DUSHMAN. *Phys. Rev.* [2] 5, 212-29(1915); cf. Langmuir, *Phys. Rev.* [2] 1, 337(1913).—A theoretical consideration of the behavior of gases at very low pressures shows that a rotating disc exerts a torque on a disc suspended above it that is proportional to the quantity $\Sigma p(M/RT)^{1/2}$, where p denotes the partial pressure and M the mol. wt. of each constituent of the gas present and R and T have the usual significance. To obtain the best results with a Gaede mol. pump it is necessary not only to heat the vessel to be exhausted and the connecting tubing to a temp. at which most of the moisture adsorbed in the walls is driven out, but also to insert a liquid air trap to prevent the back diffusion of condensable vapors. A vacuum gage is described, together with the results of some measurements carried out with it.

E. B. MILLARD.

Cyclic evolution of the chemical elements. F. H. LORING. *Chem. News* 111, 157-9(1915); cf. *C. A.* 8, 864, 1689, 1698, 1894, 1909.—Assuming Crookes' hypothesis of the evolution of the elements (*C. A.* 9, 752), L. presents an argument in favor of representing the evolution of the elements by means of a cyclic diagram similar to a hysteresis loop with internal complications, indicating changes in magnetism when the magnetizing force is periodically withdrawn and re-applied during its general progressive variation. Such a figure is essentially an energy cycle, thus keeping in the foreground the idea of work being performed in the process. It is assumed that elements can be formed when there are time breaks or "rests" in the continuity or activity of energy flow, in the sense that when the impelling or accelerating force is withdrawn or re-applied a new phenomenon asserts itself, as if the stored or impressed energy had creative power to form certain elements. This idea is expanded in the text.

E. B. MILLARD.

Determination of Avogadro's constant N from measurements of the Brownian movements of small oil drops suspended in air. HARVEY FLETCHER. *Phys. Rev.* [2] 4, 440-53(1914); cf. *C. A.* 6, 324.—Equations are derived from which N may be detd. from observable quantities. The expts. were made in a Millikan app. similar to that used in the previous expts. (*Phys. Rev.* [2] 1, 218(1913)), with some modification. The value found was $N = (60.3 \pm 1.2) \times 10^{23}$, which differs but 0.5% from the value found by Millikan, namely 60.62×10^{23} .

E. B. MILLARD.

Atomic numbers and atomic charges. FERNANDO SANFORD. *Phys. Rev.* [2] 5, 152-8(1915); cf. *C. A.* 8, 1700.—The at. charges increase as a straight line function of the at. number for the monovalent ions, but the curve for bivalent ions departs from a straight line on the low at. wt. end. Properties such as cohesion depend quant. upon the at. charges, but the magnitude of cohesion increases with increase of negative at. charge, and decreases with increase of at. charge. The m. ps. of the alkali metals may be calcd. from their at. no.; also from the relation $(N + 3)(T - 275) = 1.497$, where N is Rydberg's at. no., and T is the abs. m. p. A similar relation may be shown for many groups or closely related elements, but while within a given group the m. p. is higher the more electronegative the element, the m. p. may either increase or decrease with the at. no., as was shown in figures. Examples of increase of m. p. with increase in at. no., may be found in the groups Fe, Ru, Os; Ni, Pd, Pt; Co, Rh, Ir. With each set of triplets from which the above elements are taken, on the contrary, the m. p. decreases with increase in the at. no.

E. B. MILLARD.

Formula for calculating atomic weights. A. W. WARRINGTON. Chengtu, China. *Chem. News* 111, 110(1915).—Assuming only 85 elements between He and U, the

approx. at. wt. may be calcd. from the formula $x = -1 + 2Y + 0.008Y^2$, where x is the at. wt. and Y is the no. of the element. E. B. MILLARD.

Viscosity of iodine vapor. A. O. RANKINE. London. *Proc. Roy. Soc. London* (A) 91, 201-8(1915).—The method used for Br vapor (C. A. 7, 3876) was modified so that the I was weighed after transpiration through a capillary of known dimensions immersed in an oil bath of const. temp. The results were calcd. from the formula $\eta = (\pi R^4/16l) (p_1^2 - p_2^2)/p_0 m (d_0 T_0/T)$, where η is the coeff. of viscosity, R the radius and l the length of the capillary tube, p_1 and p_2 the pressures of entry and exit, m the mass transpired in the time t , d_0 the density of the gas at the pressure p_0 and temp. T_0 , and T the abs. temp. of the gas during transpiration. The same tube was used as in C. A. 7, 3876, having the value $1/R^4 = 3.763 \times 10^{-8} \text{ cm.}^{-4}$ at 13° . At $124^\circ \eta \times 10^4$ was 1.84, at 170° it was 2.04, at 205.5° 2.20, and at 247.1° it was 2.40. These values agree well with those calcd. from Sutherland's formula $\eta = KT^{1/2}/(1 + C/T)$, where C is a const., 590, and K is another const. E. B. MILLARD.

Vapor pressure of iodine between 50 and 95° . G. P. BAXTER AND M. R. GROSE. Cambridge, Mass. *J. Am. Chem. Soc.* 37, 1061-72(1915); cf. *ibid* 29, 127(1907).—A measured vol. of air, usually 5 to 7 liters, was passed over I, then into Na_2CO_3 soln. to absorb the I. This was then reduced with hydrazine and the iodide pptd. with pure AgNO_3 . Values were given for every 5° over the range covered, with 3 to 10 expts. for every temp. The results were lower than those of Wiedermann, Stelzner and Niederschulte (*Verh. deut. physik. Ges.* 3, 159(1905)), but formed a satisfactory extension of the earlier Harvard expts. for temps. below 50° . The results may be expressed very closely by either of the formulas: $\log p = -106.3930 + 46.611 \log T - 0.031677T$, or $\log p = 9.7522 - 2863.54(T - 19)$. The av. mol. heat of sublimation at these temps. was calcd. to be 14,700 cal., or 61.6 kilojoules. E. B. MILLARD.

Carbon molecule. F. DELLA-GROCE. *Mon. sci.* [5] 5, 25-7(1915).—The d. of a gaseous compd. is never less than the mean of the ds. of its gaseous components. Then the d. of C vapor may be calcd. from that of O_2 and CO; $x/2 + 1.10523/2 = 0.9670$, whence $x = 0.8287$. From this the ds. of various C. compds. have been calcd. and found to agree with exptl. values. Hence the vapor is C_2 , or the mol. wt. is 23.85. It was assumed that the formation of CO was from 1 mol. of O with one of C. E. B. MILLARD.

Crystallization processes in ternary systems of chlorides of univalent and divalent metals. T. LIEBISCH. *Sitzb. kgl. preuss. Akad.* 1915, 160-76; cf. C. A. 8, 3143.—Consideration of systems of 3 components A, B, and C, from which a binary compd. A_xB_y , seps. Figures and projections of space diagrams are given; together with conc.-temp. diagrams and a theoretical treatment which cannot be briefly abstracted. E. B. MILLARD.

Experiments on emulsions: Adsorption of soap in the benzene-water interface. T. R. BRIGGS. *J. Phys. Chem.* 19, 210-31(1915).—Condensation of solute in the surface segg. liquid from vapor or liquid from liquid is to be considered as a special case of adsorption. Na oleate was removed from solns. of different strengths during the process of emulsifying C_6H_6 and the amt. of this removal depended on the strength of the soap soln. and the specific surface of the C_6H_6 phase. The amt. of soap removed increased rapidly at first with small increases in conc. of the soln. then remained nearly const., showing a strong similarity to adsorption. Further work is to be done. E. B. MILLARD.

The quantitative determination of the precipitation value of hydrosols. O. HAUSER AND A. LEWITE. Berlin. *Kolloid-Z.* 16, 33-6(1915); cf. Freundlich, C. A. 4, 2764; 7, 723.—The pptn. value of different electrolytes, and varying concs. of each was detd.

by dropping the electrolyte soln. from a buret into a measured amt. of tannic acid hydrosol and stopping at the point at which a flocculent ppt. settles out rapidly, leaving a clear supernatant liquid, instead of the cloudy appearance which is maintained up to that point. With equivalent ions the pptn. power is approx. proportional to the mobility of the cation. This is preferable to the Freundlich method of adding a fixed amt. of electrolyte soln. of varying concs., allowing to stand 2 hrs. and choosing that conc. which just gives complete pptn. as the significant value, since it takes account of the speed of coagulation as well as the conc. of the electrolyte, in characterizing the electrolyte. Tables and figures show that as the conc. of the electrolyte soln. decreases there is not a proportional increase in the quantity of soln. required, so that pptn. is accomplished by less salt if in dil. soln. than in conc. up to a certain diln. beyond which pptn. cannot be accomplished.

H. I. MATTILL.

Observations on the work by O. Hauser and A. Lewite. (Cf. preceding abstract.) H. FREUNDLICH. Braunschweig. *Kolloid-Z.* 16, 36-9(1915).—The work of H. and L. simply confirms for tannic acid sol., the general statement of F. (cf. *C. A.* 7, 3874) that with decreasing electrolyte conc. the speed of coagulation rapidly decreases. It is incorrect to refer the speed to the total electrolyte conc. as the course of coagulation has removed a part of the electrolyte by adsorption. The speed of coagulation should be referred either to the quantity of adsorbed ion or the equil. conc. in the soln. The values found by the Freundlich method (conc. necessary just to give complete pptn. in 2 hrs.) are comparable with those found by a method similar to that of Hauser and Lewite, namely the conc. necessary to cause a rise of 10% in viscosity in $\frac{1}{2}$ hr. Applying this method to $\text{Al}(\text{OH})_3$ sol and NH_4Cl , $\text{K}_4\text{Fe}(\text{CN})_6$ and K benzoate the molar concs. for equal speeds are 100, 0.09 and 14 molar, showing the difference between a monovalent, a tetravalent anion (adsorbed by basic $\text{Al}(\text{OH})_3$) and a little adsorbed inorganic, and a highly adsorbed organic monovalent anion. The method of H. and L. is open to criticism in that with the large quantities of very dil. electrolyte there is a marked progressive change in the conc. of the sol and electrolyte, during one detn.

H. I. MATTILL.

Coagulation and peptization of albumin sols by means of suspension colloids in solutions containing electrolytes. A. BROSSA AND H. FREUNDLICH. Brunswick. *Z. physik. Chem.* 89, 306-37(1915).—A number of the properties of albumin solns. (from cow serum) which are as free as possible from electrolytes have been detd., and the negative charge and the non-precipitability by heavy metals (FeCl_3 , ZnSO_4 , HgCl_2), have been confirmed. Further, it has been shown that the precipitability of albumin solns. by a positive $\text{Fe}(\text{OH})_3$ sol, as well as by a negative MoO_3 sol, increases proportionately with the decrease of the electrolyte in the liquid; finally only a slight turbidity makes its appearance which, on further addition of the pptg. sol, dissolves again. The properties of albumin- $\text{Fe}(\text{OH})_3$ sols have been investigated, and it has been found that the small particles of these sols are positively charged, but to a much less extent than is the case with pure $\text{Fe}(\text{OH})_3$ particles. It is evident from this that an albumin- $\text{Fe}(\text{OH})_3$ sol behaves like a positive suspension colloid that is pptd. in small concns. of electrolytes, in connection with which the nature of the anion, its valence and adsorbability are of marked importance. However, the concns. necessary to bring about pptn. are markedly smaller than in the case of pure $\text{Fe}(\text{OH})_3$ sols. At higher concns. of electrolyte, the particles which first coagulate peptize again. The nature of the anion is of special importance in this connection. It is shown that the albumin is not quant. united to the $\text{Fe}(\text{OH})_3$, but is distributed between the latter and the soln. It has been found that the adsorption isotherm does not hold, but that, for small albumin concns., the amt. of the latter adsorbed is proportional to the quantity in the soln., while for higher concns. a satn. value is reached. With increasing $\text{Fe}(\text{OH})_3$ content

the upper non-pptn. zone disappears, and the albumin-Fe(OH)₃ sols. become more and more like the pure Fe(OH)₃ sols. The albumin-Fe(OH)₃ sols are much more turbid to the eye than the pure Fe(OH)₃ sols.

H. JERMAIN CREIGHTON.

Observations on "colloidal arsenates" by G. Klemp and J. Gyulai. E. DEISS. Berlin-Steglitz. *Kolloid-Z.* 16, 16(1915); cf. *C. A.* 9, 1142.—Deiss has shown (cf. *C. A.* 8, 2658) contrary to the conclusions of Klemp and Gyulai, that "manganous arsenate gel can be formed only in the presence of NH₄ salts and AcOH," that a transparent gel can be formed in the absence of these materials when KH₂AsO₄ is used instead of Na₂AsO₄.

H. I. MATTILL.

Ultramicroscopy and colloidal solutions. W. BACHMANN. Goettingen. *Naturwissensch.* 3, 181-4(1915).—A criticism of present methods.

C. G. F.

Osmotic pressure of alcoholic solutions. I. Vapor pressures and densities. T. W. PRICE. *J. Chem. Soc.* 107, 188-98(1915); *Proc.* 30, 269-70.—Vapor pressures of solns. of carbamide in EtOH at 40, 50, 60 and 70°, and of PhNO₂ at 20, 30, 40, 50 and 60° for several concns. have been made by the method of Perman and Price (*C. A.* 7, 929). Results by this (air bubbling) method agree with the detns. of others well enough to show that Dalton's law of partial pressures holds, and that the vapor d. of EtOH is normal. Babo's law, according to which $(p - p')/p$ is independent of temp., was found to hold. Osmotic pressures of the solns. have been calcd.

E. B. MILLARD.

Superficial tension and hydration in solution. M. PADOA AND G. TABELLINI. Univ. Bologna. *Gazz. chim. ital.* 45, I, 99-106(1915); see *C. A.* 8, 2092. E. J. W.

Diffusion in solutions. J. THORVERT. *Ann. phys.* 2, 369-427(1915).—A long introduction is followed by data on the diffusion of NaCl at different temps. from 7.4 to 31.4°. The diffusion coeff. increased from 0.94×10^{-5} at the lower temp. to 1.88×10^{-5} at the higher temp. The diffusion of one substance in the presence of another was also investigated for EtOH, sugar, acids, bases and salts; then the diffusion of PhOH in several solvents. The diffusion coeffs. of a large number of organic substances in H₂O, MeOH and C₆H₆ are presented in a long table, and the results are discussed.

E. B. MILLARD.

The coefficient of diffusion in dilute solutions. BASIL W. CLACK. Birkbeck College. *Proc. Phys. Soc. London* 27, 56-68(1914); cf. *C. A.* 4, 400.—The app. previously described (*Ibid* 21, 863 (1908) and 24, 40(1911)) has been modified so that detns. of the coeff. of diffusion, K , of salts through H₂O may be quickly made, the steady state obtaining in about 1 day. The following values were observed, the first row indicating normality and the following rows $K \times 10^5$:

Normal.	0.05.	0.10.	0.20.	0.40.	0.60.	0.80.	1.0.	1.5.	2.0.
KCl.....	1.388	1.430	1.467	1.493	1.504	1.515	1.527	1.555	1.584
KNO ₃	1.453	1.421	1.374	1.319	1.276	1.233	1.190	...	...
NaCl.....	1.165	1.170	1.177	1.188	1.198	1.208	1.216	1.235	1.253

PAUL D. FOOTE.

Ionization equilibrium. JAMES KENDALL. Columbia Univ. *J. Phys. Chem.* 19, 193-209(1915).—The increase in the dissociation const. of acids in aq. soln. when the ionic concn. is large was represented for acids of all strengths by the empirical equation $\gamma/(1 - \gamma) v = k + c(1 - \gamma)/\gamma$. The decrease in the dissociation const. when the total concn. is large was found to disappear under the assumption that ionization is not spontaneous, but induced by the solvent. The assumption is defended, and the dissociating power of the solvent ascribed to its unsatd. character, i. e., free valences.

E. B. MILLARD.

Equilibrium in the system: water-alcohol. N. A. PUSHIN AND A. A. GLAGOLEVA. *J. Russ. Phys. Chem. Soc.* 47, 100-113(1915).—A study of the diagram of state of the system $\text{H}_2\text{O}-\text{EtOH}$ by the fusion method, using liquid air as cooling agent, gave the following results: The diagram consists of 2 curves intersecting at the eutectic point -118° (85 mol. % of alc.). H_2O forms with cryst. alc. solid solns. whose limit of concn. is 15 mol. %, while alc. forms no such solns. with ice. Contrary to the statements of several investigators, there are no definite chem. compds. of H_2O and alc. either in the liquid or the solid phase. The mol. depression of alc. (for 1 g. mol. of substance in 1000 cc. of alc.), as found by expts. with solns. of CHCl_3 or C_6H_6 in alc., is probably 3. For H_2O as solute it is about 1.9. The difference is due to the formation of solid solns. in the latter case.

H. M. GORDIN.

The solution velocity of molecular layers. GEORG V. HEVESY AND E. RONA. Budapest. *Z. physik. Chem.* 89, 294-305(1915).—The soln. velocity of mol. (infinitely thin) layers shows the same qual. behavior as layers of finite thickness. The soln. velocity of Pb and Bi isotopes in HNO_3 increases with the acid concn., with diminution of the viscosity and with the abs. solubility of the substance. The presence of Pb ions in the soln. decreases the soln. velocity of the Th B which is isotopic with the Pb, while it does not influence that of the Th C which is isotopic with Bi.

H. JERMAIN CREIGHTON.

The mobility of some polyvalent cations in water. A. HEYDWEILLER. Rostock. *Z. physik. Chem.* 89, 281-6(1915).—The electrolytic mobility of the polyvalent cations, Be^{++} , Al^{+++} , Cr^{+++} , Mn^{++} , Fe^{++} , Fe^{+++} , Ni^{++} , Co^{++} , La^{+++} , Sm^{+++} and Th^{++++} , have been detd. by a graphic method. The method is based on the following: If instead of the special concns., m , (g. equiv. per l. soln.), the so-called linear concns., $\sqrt{V/m}$, are plotted as abscissas against the equiv. conds. as ordinates, there is obtained for an electrolyte, within wide limits of concn., an approx. straight line curve. The point where this curve cuts the axis of ordinates represents the equiv. cond. at infinite diln. of the electrolyte. The values obtained in this way for a number of electrolytes have been found to agree, within a few %, with those obtained by other methods. From the values for the equiv. cond. at infinite diln., the electrolytic mobilities have been calcd. in the usual way.

H. JERMAIN CREIGHTON.

Magnetic susceptibility and electrolytic dissociation. A. QUARTAROLI. R. Ist. Tecnico, Pisa. *Gazz. chim. ital.* 44, II, 43-63(1914).—The methods used in the detn. of magnetic susceptibility of solns. are applicable only in cases in which the solns. are not excessively dil. and accurate detns. are only obtained in strong fields (5000-30000 gauss). Quincke (*Wied. Ann.* 24, 347(1885)) used a U-tube, the 2 arms of which had unequal diams., the smaller arm being placed between the poles of the electromagnet. The level of the liquid rises or falls depending on whether it is dia- or paramagnetic in a way proportional to the magnetic susceptibility and the square of the field intensity. In aq. solns. the diamagnetic properties of H_2O must be considered in detg. the susceptibility of the soln. A soln. of FeCl_3 (2.85 g. per l.) shows a susceptibility of -1.20×10^{-7} , in abs. units; that of H_2O is -7.8×10^{-7} , so that of the solute is 6.6×10^{-7} . The general results for organic compds. are briefly reviewed. In the inorg. compds. the question of the effect of electrolytic dissociation arises. With the complex derivs. especially the results are incomplete. Quincke observed a lower magnetic susceptibility for EtOH solns. of magnetic salts. Pascal (cf. *C. A.* 2, 2762) found that solns. of FeCl_3 , $\text{Fe}_2(\text{P}_2\text{O}_7)_3$, in NH_4OH and $\text{K}_3\text{Fe}(\text{CN})_6$ containing 2.85 g. Fe per l., resp., gave -1.20×10^{-7} , -3.71×10^{-7} and -6.55×10^{-7} as the constants of susceptibility, showing that a decrease of the chem. property of Fe from an analytic point of view is accompanied by an analogous decrease in magnetic property. Drapier (*C. A.* 4, 273) followed the diminution and extinction of the magnetic property with salts of Fe, Cr, Mg and Ni

in which the metal was combined in a complex anion, and found that in Et_2O soln. FeCl_3 is not paramagnetic. He tried to establish a relation between the conc. of the Fe ion and the susceptibility. Q. has extended the observations to solns. of Fe, Mn, Ni and Co salts alone and in the presence of mannitol, NH_4Cl , citrate or tartrate. The quant. method of Quincke was used and qual. expts. with the author's own method were made; a field of 3000 gauss was sufficient for dil. solns. If a tube 9–10 mm. wide 0.5 full of a mag. soln. is placed between the poles of an electromagnet, and if a little H_2O colored with the same substance is placed upon the liquid with a pipet, and if the line of sepn. is in the center of the field, nothing is observed. When the tube is lowered in a strong field the surface of sepn. remains between the poles, this surface bulges downward until it forms a bubble of colored water in a magnetic liquid. A little KMnO_4 in the dil. soln. shows the effect more strikingly. If the diamagnetic soln. is more dense than the magnetic the phenomenon is reversed; the bubble projects upward. The magnet best adapted for these expts. was a hollow cylinder which was beveled off with hollow cones with a generatrix 45° with the plane of the base. Knowing the d. of the solns. used, quant. results may be obtained which compare favorably with those obtained by Quincke's method. *Expts. with a weak magnetic field.* These expts. were made with a small electromagnet (110 v.) which had a field of 3500 gauss. The degree of magnetism of solns. of salts of Mn, Fe, Co and Ni vary as 6:5:4:2. Ten cc. of MnCl_2 (4.80 g. Mn per 100) were made up to 50 cc. and tested in the field as described and gave the bubble (Fig. I). To this soln. (d. 1.026)

KNO_3 was added until d. 1.040; Fig. II was obtained. When the soln. was dild. to 25 vols. the effects were distinct. At a dild. of 250 vols. the soln. contained 0.0192% Mn or 1 g. in 5200 g. H_2O , and still showed the effect as in Fig. III. Solns. of KMnO_4 and K_2MnO_4 do not show the effect. Variable results were obtained with colloidal MnO_2 . Ten cc. of the MnCl_2 soln. + 10 cc. of N NH_4 tartrate + 5 cc. NH_4OH (d. 0.92) placed on an NH_4 tartrate soln. containing NH_4OH and phenolphthalein showed the typical figures. Using NH_4 citrate instead of tartrate gave the same result. Using FeCl_3 (1.792 g. Fe per 100) the figures were like II. When NH_4 citrate or tartrate were added as above the figs. were like II. When mannitol was added instead of the above the figs. were like III, *i. e.*, the polyvalent alcs. cause a marked decrease in susceptibility. A FeSO_4 soln. (1.792 g. Fe per 100) shows a weaker effect than FeCl_3 , but in the NH_4 citrate and tartrate solns. the mag. susceptibility changes owing to oxidation. With solns. of CoCl_2 and NiCl_2 (3.855 and 3.060% Co and Ni, resp.) the effects are much the same but weaker especially for Ni. The same is true in the presence of NH_4 citrate and tartrate. With NH_4Cl + NH_4OH the susceptibility changes on standing; this change is hastened by adding PbO_2 . *Expts. with a strong magnetic field.* This magnet was capable of 30000 gauss. The expts. were made (1) to det. the sensibility of the qual. method in an intense field; (2) to follow the expts. at different intensities in order to obtain the same figs. and thus follow more approx. the comparison of various solns.; (3) to verify results obtained by the classical U tube method which disagree with principles that have been proposed on the relation between dissociation and mag. susceptibility. The strength of the field was detd. for known currents so that when the intensity was changed the strength of field could be known. The FeCl_3 soln. dild. to 2500 vols. showed a fig. like III at 15600 gauss. MnCl_2 hydrolyzes less easily than FeCl_3 and shows Fig. III at a dild. of 16625 with a field of 16650 gauss. With 1 part Mn per 1000000 a field of 30000 gauss gave Fig. III. If NH_4 citrate, tartrate or quinate were added to FeCl_3 solns. stronger fields were required to give the same effect as without; still stronger ones were required when mannitol was added. The same relations hold for MnCl_2 , CoCl_2 and NiCl_2 . Quant. data

and other details are given that cannot be abstracted briefly. In general, the results throughout show that the relation between electrolytic dissociation and magnetic susceptibility is not simple as some authors, who state that susceptibility depends on the conc. of the free ions of the magnetic elements, have thought. It seems clear that one condition necessary for magnetic elements to show considerable susceptibility in soln. is the presence of an elec. charge either free or not. This is shown by the low susceptibilities of magnetic salts in EtOH or Et₂O soln., and by the fact that Fe²⁺ shows only about $\frac{1}{2}$, as much susceptibility as Fe³⁺ salts. Pascal (*l. c.*) found a gradual change in susceptibility as complexity increased. Q. says that what is called greater or less complexity of ions really refers to a greater or less partial dissociation. Complex ions are weakly dissociated so that sometimes they fail to give certain characteristic reactions. In most cases when one passes from an ordinary salt of a metal to the less complex of its complex salts a diminution of conc. of the free ions occurs in which the difference in conc. between the complex and the other is negligible. If the susceptibility of Fe₃(P₂O₇)₂ and K₂Fe(CN)₆ is due to free Fe ions that of the 1st should be many times less than that of FeCl₃. So that it has been detd. that there is apparently no relation between the conc. of free ions and susceptibility; it depends solely on the chem. comp. of the complex. Admitting now that the susceptibility depends solely on the comp. of the complex ion containing the magnetic element the question as to the explanation of the action of the other elements or groups arises. Q. suggests that in org. chemistry the constitutive constns. of susceptibility must be changed for each group of compds. examd. and that there should be no surprize that the same holds true for inorg. compds. The atomic contribution to the phys. constns. of compds. is a variable that depends on the other atoms and probably on the nature of their arrangement. The fact that inorg. compds. undergo electrolytic dissociation simply complicates the problem somewhat when complex compds. are under consideration.

E. J. WITZEMANN.

Anomalous electrolytic dissociation. A. SAKHANOV. *Z. Elektrochem.* 20, 529-37 (1914).—S. discusses the most important regularities observed among electrolytes showing anomalous electrolytic dissociation and the various theories proposed to account for their behavior. Part of the paper is polemical in nature and devoted to a paper of Kraus (*cf. Z. Elektrochem.* 20, 524-7) in which S. concludes that the explanation of the anomalous phenomena presented by Kraus and Bray (*cf. C. A.* 8, 854) is very dubious.

E. C. MCKELVY.

Electrolysis of glass. A. SPERANSKII. *J. Russ. Phys. Chem. Soc.* 47, 52-8 (1915).—An elec. current was passed through glass immersed in conc. H₂SO₄ at 230-320°, and the changes in the comp. of the glass and the liquid and in the strength of the current were examd. The results are summarized as follows: With H₂SO₄ as anode liquid there is a radical difference in the behavior of ordinary Na glass and other varieties (Jena, Pb glass, etc.), the latter behaving exactly as with Hg as anode liquid (Warburg, *Wied. Ann.* 21, 622), while the Na glass becomes opaque, and the cond. at first drops, but then quickly rises above the original value.

H. M. GORDIN.

Absorption of hydrogen by sodium-potassium electrodes. R. C. GOWDY. Univ. Cincinnati. *Phys. Rev.* 4, 401-8 (1914).—The rate of absorption of H by Na-K cathodes in glow discharge tubes has been measured for currents of 0.2 to 4.7 milliamp. for a cathode 30 mm. in diam.; and for currents of 0.2 to 2.0 milliamp. for a cathode 16 mm. in diam. At c. d. less than 0.5 milliamp. per sq. cm. the rate of absorption is approx. 10 times that at which H is liberated in electrolysis by an equal current. With greater c. ds. the rate of absorption becomes const. The rate of absorption increases with increasing temp. of the cathode. An "equil." pressure has been found at which Na-K electrodes neither absorb nor evolve gas. This pressure depends on the current and the quantity of hydride on the surface of the alloy. At pressures of 1 to 2 mm.,

Na-K anodes absorb H, and at low pressures evolve it. The rate of this evolution for various pressures and current strengths has been measured. NaH and KH are decompd. by cathode rays. The cathode absorption and anode evolution are regarded as due to the formation or decompn. of the hydrides by local heating effects of the impinging charged particles, according as the temp. is favorable to one or the other of these processes.

E. B. MILLARD.

The molecular magnitude of metals in the solid phase. M. PADOA AND F. BOVINI. Univ. Bologna. *Gazz. chim. ital.* 44, II, 528-34(1914).—A knowledge of the mol. magnitude of substances in the solid state is important for possible deductions on phys. properties and serves as a basis of the kinetic theory of solids. Tammann (C. A. 6, 819, 1388) has offered some criteria based on the diagram of state which however are difficult to apply in certain interesting cases. The results of Heycock and Neville by the cryoscopic method show that the metals and certain metalloids are monatomic in liquid solns.; the data seem to indicate that C is monatomic in soln. in Fe. The results of Rudolphi (*Z. anorg. Chem.* 53, 218) for Cu-Si show Si to be monatomic in this alloy. It is clear that once the mol. wts. under such conditions are certainly known it will be possible to compare the phys. properties of monatomic and polymerized Si which will be advantageous in settling various questions. By this means the deduction of the law of Dulong and Petit and deviations which it undergoes will be explained, and it may be found that the elements showing the greatest deviations are those with small at. vols. that have a greater tendency to polymerization and that give allotropic forms easily. When from a dil. soln. C_1 one seps. a solid soln. of conc. C_2 and the ratio $C_2:C_1$ is constant then it may be said that the substance dissolved has the same mol. magnitude in the solid as in the liquid state. A 3rd substance must be present in order to make a detn. of the amt. of mother liquor present in the solid possible. Not many ternary alloys are adapted to this work. Alloys of Sn, Cd and Bi were used. Sn-Cd forms a eutectic and limited solid solns. which at a little above 100° are transformed into a compd., Sn_4Cd . Sn-Bi and Cd-Bi also give eutectics but no solid solns. The 3 alloys examd. solidified at about 200° but showed no further complications. With Sn 90.27, Cd 4.79, and Bi 4.94% the ratio of $C_2:C_1$ is 0.986; with Sn 88, Cd 8 and Bi 4% the ratio is 0.985; with Sn 85, Cd 10 and Bi 5%, the ratio is 0.957. This shows that the solid solns. sepg. from different liquid solns. of Cd in Sn have approx. the same conc., showing that the coeff. of distribution is practically constant. It is concluded that Cd has the same mol. magnitude in solid soln. in Sn as in liquid soln., i. e., it is monatomic. These results confirm Stoffels data concerning these ternary alloys.

E. J. WITZEMANN.

Studies in catalysis. II. Inversion of sucrose. ALFRED LAMBLE AND WM. C. McC. LEWIS. Univ. Liverpool. *J. Chem. Soc.* 107, 233-48(1915); cf. C. A. 9, 262.—The rates of inversion of sucrose by means of HCl at 25° , 35° , and 45° were measured, using the polarimetric method. Five concs. of HCl were used in each set of expts., varying from 0.0502 *N* to about 1.2 *N* in the measurements taken at 25° and 35° , and from 0.0502 *N* to 0.9 *N* in the expts. at 45° . From the velocity consts. k_i the values of the temp. coeffs. k_{35}/k_{25} and k_{45}/k_{35} and their change with change in concn. of catalyst were detd., taking into consideration the total catalytic effect due to H^+ and to undissociated HCl (the latter being about twice that of the H^+ at 25° and 1.5 times as great at 45° (cf. McBain, C. A. 8, 3141)). The mean value $k_{35}/k_{25} = 4.13$; the mean value $k_{45}/k_{35} = 3.73$. Transforming the Marcellin-Rice formula, $d \log k/dT = E/RT^2$, where E is the "critical increment" for sucrose (i. e., the extra amt. of energy which 1 gram-mol. of the system requires) into the equation $\log_e (k_{35}/k_{25}) = (E/R)(1/298 - 1/308)$, the value for $E = 26000$ cal. per gram-mol. and each sucrose mol., in order to enter the reaction requires $26000/6.85 \times 10^{23}$ cal. or 1.6×10^{-12}

egs. Applying Einstein's law that 1 mol. reacts by absorbing 1 quantum ($h\nu$, where h = Planck's const. and ν = vibration frequency of the radiant energy absorbed), $\nu = 1.6 \times 10^{-12} / 6.55 \times 10^{-27} = 2.44 \times 10^{14}$. Since the wave length corresponding with this is 1.23μ which lies in the region of marked absorption of the infra-red absorption spectrum of sucrose, the mechanism whereby velocity of reaction is increased by raised temp. may be accounted for by a radiation hypothesis. The H ion probably emits radiations of wave lengths lying between 1 and 10μ which in the case of this reaction may be absorbed by the sucrose. The value E falls slightly as the concn. of catalyst increases and a review of the literature (given in full by L. and L.) shows that for reversible reactions the greater the value of k the smaller the value of E , and *vice versa*. Both of these conclusions are in agreement with the Marcellin-Rice equation and with the theory that chem. reactivity is due to infra-red radiation. L. and L. also discuss the possible catalytic action of the undissociated mol. from the radiation point of view.

LOUIS E. WISE.

Use of nickel and its oxides in catalysis. J. B. SENDERENS AND J. ABOULENC. *Bull. soc. chim.* 17, 14-9(1915).—Discussion of the work of Ipat'ev (*J. Russ. Phys. Chem. Soc.* 38, 75-92; 39, 693-703(1907)) on hydrogenation with Ni and NiO catalyzers. At 180° a mixt. of H (in excess) and C_6H_6 vapor reacted to form cyclohexane almost completely in the presence of Ni (formed from the reduction of NiO) and in the absence of moisture; in the presence of NiO there was practically no reduction. With moist H and some of the same NiO, the reduction of PhOH at 180° proceeded rapidly and with the evolution of much heat. As much as 125 l. of H were absorbed in 2 min. Finely divided Ni acted equally well with or without moisture in the hydrogenation.

E. B. MILLARD.

Velocity of saponification of linalyl, terpenyl and geranyl acetates. C. L. BARILLET AND R. BERTHELE. Geneva. *Bull. soc. chim.* 17, 20-8(1915).—Expts. on the speed of saponification at 78° , 0° and at $15-16^\circ$ by $0.5 N$ KOH of the esters mentioned. The amts. saponified in a given time by different amts. of KOH were: 73% with 25 cc., 78% with 50 cc., and 82% with 100 cc. at room temp.

E. B. MILLARD.

Piezochemical studies. XIII. The influence of pressure on the reaction velocity in condensed systems. II. ERNST COHEN AND H. F. G. KAISER. Utrecht. *Z. physik. Chem.* 89, 338-64(1915); cf. C. A. 7, 3056(1913).—The influence of pressure on the esterification velocity of $0.01 N$ Et acetate by $0.01 N$ NaOH has been studied at 2.40° between 1-1500 atms. Two methods have been employed in the investigation, which give the same results. The velocity of reaction at 1500 atms. is 37.4% greater than at 1 atm. It has been found that the influence of pressure on the velocity of reaction may be as well described by the linear equation, $k_p = a + bp$, as by the van't Hoff equation, $d \ln k / dp = \text{const.}$, in which k is the reaction velocity, a is the % increase in concn. due to compressibility, p is pressure, l is the reciprocal of the measured resistance of a $0.01 N$ NaOH or NaOAc soln.

H. JERMAIN CREIGHTON.

Mercury iodide. I. A. SMITS AND S. C. BOKHORST. Amsterdam. *Z. physik. Chem.* 89, 365-73(1915); cf. C. A. 5, 1861(1911).—The system HgI_2 has been studied in the light of the theory of allotropy, and the retardation expts. continued. The continuous change from yellow to red which HgI_2 exhibits above 127° , combined with the fact that molten HgI_2 is a dark red liquid, which on sudden cooling gives a homogeneous solid red phase that cannot be distinguished from the usual red modification, when taken in conjunction with the fact that HgI_2 vapor is yellow, leads to the same T, X diagram as given in the previous communication. The results of the expts. are readily explained by means of this diagram.

H. JERMAIN CREIGHTON.

Mercury iodide. II. A. SMITS AND S. C. BOKHORST. Amsterdam. *Z. physik. Chem.* 89, 374-82(1915); cf. previous abstract.—The fusion lines of HgI_2 in the binary

systems nitrobenzene-HgI₂ and nitrotoluene-HgI₂ have been detd. The transition point is 127.5° and 128°, resp. The fusion lines are continuous from this temp. to the fusion point of the HgI₂, and show from $\approx 240^\circ$ to $\approx 250^\circ$ a very marked increase of dX/dT . It has been demonstrated that the transition of HgI₂, which is associated with the color change above 127°, progresses continuously, and that in the temp. region in which the color change is greatest, the value of dX/dT of the fusion line experiences the greatest change, as would be expected on theoretical grounds.

H. JERMAIN CREIGHTON.

Fractional distillation with regulated still heads. II. M. A. ROSANOFF, J. F. W. SCHULZE AND R. A. DUNPHY. Pittsburgh. *J. Am. Chem. Soc.* 37, 1072-9(1915); cf. *C. A.* 8, 3523, 3735, 3742; 9, 877.—Further expts. in ternary mixts. of CCl₄, C₆H₆-CH₃, and C₂H₄Br₂ distd. with heads at regulated temps. At each temp. the vapors had the same comp. as the vapors evolved would have if the mixt. were boiling at the temp. of the still head. Variations in the comp. of the distillate during a single expt. were slight, but always present. In a binary mixt. the comp. of the distillate was const. for each expt. An important limitation of the rule for ternary mixts. was reserved for the next paper of the series.

Heats of combustion of aromatic hydrocarbons and hexamethylene. T. W. RICHARDS AND FREDERICK BARRY. Harvard. *J. Am. Chem. Soc.* 37, 993-1020 (1915); cf. *C. A.* 4, 1465; 8, 1048, 3734.—An Atwater bomb (*J. Am. Chem. Soc.* 25, 659(1903)) wholly lined with Pt was used. The Pb gasket was replaced with one of soft Au bearing on a double ridge. Heats of combustion have been detd. for sucrose, C₆H₆, MePh, EtPh, mesitylene, pseudocumene, *i*- and *n*-propylbenzene, tertiary butylbenzene, and cyclohexane, in the adiabatic calorimeter previously described. The max. deviations from the means for the 5 or 8 expts. with each substance were about 0.05%. Data are given in 18° Cals., using sucrose as a standard (heat of combustion 3.945 Cals. per g.), as follows: C₆H₆ 9.993, MePh 10.166, *o*-xylene and *m*-xylene 10.277, *p*-xylene 10.241, C₆H₅C₂H₅ 10.273, 1,3,5-C₆H₂Me₃ 10.340, *n*-C₆H₅C₃H₇ 10.364, cumene 10.371, 1,2,4-C₆H₃(CH₃)₃ 10.316, C₆H₅C(CH₃)₃ 10.427, cyclohexane 11.164.

E. B. MILLARD.

Formula connecting pressure and temperature of saturated steam. S. GODBEER. *Engineering* 99, 290(1915); cf. *C. A.* 7, 1314.—The previous 6 const. equation has been replaced by another empirical one in which only 5 const. are used. If *p* is in mm. of Hg, the formula is $\log p = 25.08199929 - [(43833 - 13t)/(73386 + 110t)^2/3885969 - 0.876(9112 + 3t)(273 + t)]$. Below 7° the exptl. results fit the formula $\log(p + 0.91216) = 0.7396675 + 0.0265617t$.

E. B. MILLARD.

Electrically heated full radiator. H. B. KERNE. Univ. Birmingham. *Proc. Roy. Soc. London (A)* 91, 190-7(1915).—Pt strips wound directly on alumina crucibles adhered to the walls and were broken on cooling. Strips which had been crimped between 2 cog wheels were wound on a bottle-shaped crucible with a small circular aperture opposite the conical bottom. The stiff strips were wound into a cage-like structure held in place by mica and placed over the conical end of the "bottle." These were then packed in alumina, and the sides of the bottles were packed with infusorial earth about 10 cm. deep. A small opening was made in the side for the thermo-junction. Using 1750 watts, the temp. of the furnace was maintained uniformly at 1150°. The radiation from the aperture differed from the full radiation at that temp. by an amt. probably not exceeding 0.2%.

E. B. MILLARD.

Thermodynamic considerations on photochemical equilibrium. A. SCHIDLÖF. *Arch. sci. phys. nat.* 38, 31-5(1914).—S. shows that the law of photochem. equil. can depend only on the expression ν/T , where ν is the frequency and *T* is temp. of the mono-

chromatic radiation. The only assumptions used are (1) the thermochem. equil. of a system is independent of the temp. and (2) the equil. is independent of the pressure. It is then shown that the analytical expression given in a previous paper (C. A. 8, 265) for the influence of radiation on photochem. equil. is a function of ν/T .

O. A. RANDOLPH.

Experiments on ammonia. F. HABER. II. Redetermination of the ammonia equilibrium under thirty atmospheres pressure. S. TAMARU AND CH. PONNAZ. Berlin-Dahlem. *Z. Elektrochem.* 21, 89-106(1915); cf. C. A. 1, 2342; 2, 2326; 3, 11; 4, 1653, 2356; 8, 3101.—A new study of the equil. $N_2 + 3H_2 \rightleftharpoons 2NH_3$ at 30 atm. between 560° and 950°, using Os as a catalyzer. Results agree fully with those of Haber and Le Rossignol carried out at the same pressure but in a narrower range of temperature. The formula $\log K_p = (13200/4.571T) - 6.134$ was found to apply, in which K_p is defined by the partial pressures of the three gases involved: $K_p = P_{NH_3}/P_{H_2}^{3/2} P_{N_2}^{1/2}$.

A. F. O. GERMANN.

The stability of thermodynamic equilibrium and statistical mechanics. A. SCHIDLOF. *Arch. sci. phys. nat.* 39, 25-46(1915).—Using the hypothesis that the state of the smallest elements of a body is defined by the same variables as the state of the entire body, S. is able to proceed from abstract thermodynamics to some of the chief results of statistical mechanics.

O. A. RANDOLPH.

Thermodynamics of normal elements. VI. ERNST COHEN AND W. D. HELDERMAN. Utrecht. *Z. physik. Chem.* 89, 287-93(1915); see C. A. 9, 879. H. J. C.

Entropy of vaporization as a means of distinguishing normal liquids. J. H. HILDEBRAND. Univ. Calif. *J. Am. Chem. Soc.* 37, 970-8(1915); cf. C. A. 8, 3734.—The entropy of vaporization (i. e., the mol. heat of vaporization divided by the abs. temp. at which the vaporization takes place) is the same for all normal liquids, when the evapn. takes place "at the same conc. of vapor," but not when (as in Trouton's rule) it takes place at the same pressure. This fact was expressed in a vapor pressure equation contg. a single const. characteristic of the liquid, the const. being detd. from the temps. necessary to give the same conc. of vapor in the different cases.

E. B. MILLARD.

The Schroeder paradox. L. K. WOLFF AND E. H. BÜCHNER. Univ. Amsterdam. *Z. physik. Chem.* 89, 271-80(1915).—The phenomenon, observed by Schroeder (cf. *Z. physik. Chem.* 45, 75), connected with the swelling of gelatin that seems inconsistent with the 2nd law of thermodynamics, has been investigated. The expts. performed lead to the conclusion that the supposed contradiction of the second law of thermodynamics is erroneous.

H. JERMAIN CREIGHTON.

On the metastable continuation of the fusion line and the mixed crystal line, and on the connection with the phenomena of monotropy and enantiotropy. A. SMITS. Univ. Amsterdam. *Z. physik. Chem.* 89, 257-70(1915); see C. A. 9, 1266.

H. JERMAIN CREIGHTON.

Electromotive forces in alcohol. IV. Combinations of the hydrogen and calomel electrodes. R. FURNESS, R. T. HARDMAN AND E. NEWBERRY. Manchester. *J. Chem. Soc.* 105, 2302-9(1914); *Proc.* 30, 233-4; cf. C. A. 6, 1565; 7, 1652.—Expts. are described on the e. m. f. of cells in which satd. solns. of NaCl in EtOH contg. HCl at various concns. have been measured in various combinations with H and calomel electrodes. All of the experiments were at 25°. Several LiCl cells were measured. With the use of other data (to be given later) the thermodynamic potential of HCl at very great dilns. will be calcd. in both H₂O and EtOH, and the 2 values compared. A theoretical analysis of the data shows that 3 of the 4 cells above are probably correctly detd., and that the calomel electrode is not satisfactory in acid-alc. solns., but that it is trustworthy in alc. solns. of NaCl.

E. B. MILLARD.

Liquids of constant boiling point for use in constant temperature heating baths. A. GOLODETZ. *Chem. Ztg.* 38, 1253(1914); *J. Soc. Chem. Ind.* 34, 167-8.—In the following list 2 classes of liquids with const. b. ps. are included: (a) mixts. in definite proportions of 2, or 3, miscible liquids; (b) heterogeneous mixts. (in any proportion provided 2 liquid phases are present) of 2 immiscible liquids. The b. ps. given in the list are the temps. of the vapors when the liquids are in ebullition; these are followed by a statement of the comp.: 33°, H₂O and ether (heterogeneous); 36.5-37.5°, alc. (3), EtBr (97); 38°, CS₂ (87), MeOH (13); 39-40°, CS₂ (71), AcOMe (29); 42.5°, CS₂ (91), alc. (9); 53.5-54.5°, MeOH (12), CHCl₃ (88); 55.5°, MeOH (20.6), CCl₄ (79.4); 58°, MeOH (38.4), C₆H₆ (61.6); 59-59.5°, alc. (6), CHCl₃ (94); 62°, MeOH (47), AcOEt (53); 64.8°, C₆H₆ (74.1), alc. (18.5), H₂O (7.4); 68°, alc. (32.4), C₆H₆ (67.6); 71.5° alc. (31), AcOEt (69); 74.8°, CCl₄ (77.15), alc. (22.85); 79.5°, C₆H₆ (90.5), isobutyl alc. (9.5); 84.5°, H₂O and toluene (heterogeneous); 87.7°, H₂O (28.3) propyl alc. (71.7); 91-91.5°, propyl alc. (53), toluene (47); 92.5°, H₂O (41), pyridine (59); 94-94.5°, H₂O and turpentine (heterogeneous); 95°, H₂O (7), chloral (93); 98.5°, H₂O and ethylaniline (heterogeneous); 99°, H₂O and diethylaniline (heterogeneous); 104°, toluene (70), AcOH(30); 113-113.5°, AcOH (27), xylene (73); 121-122°, amyl alc. (30), ethylene dibromide (70); 125-126°, amyl alc. (52), *m*-xylene (48).

F. W. SMITHER.

Wheatstone bridge for resistance thermometry. C. W. WADNER, H. C. DICKINSON, E. F. MUELLER AND D. R. HARPER. *U. S. Bur. Standards Sci. Paper* 241, 20 pp. (1915).—The bridge described was designed with special reference to flexibility for use in measurements with resistance thermometers, either Siemens or Callender type, or with the potential terminal type with Thomson double bridge. It was arranged so that it could be completely self-calibrated. The accuracy was about 1 in 300,000 with resistances of an ohm or more, corresponding to about 0.001° with a Pt resistance thermometer.

Flicker photometer measurements by a large group of observers on a monochromatic green solution. H. E. IVES AND E. F. KINGSBURY. *Phys. Rev.* 5, 230-5 (1915); cf. *C. A.* 8, 3639.

E. B. MILLARD.

Electrical, photoelectrical and electromechanical properties of certain crystals of selenium, with applications to crystal structure. F. C. BROWN. *Phys. Rev.* [2] 5, 167-75(1915); cf. *C. A.* 8, 1233, 3264, and the expts. of Bragg (*C. A.* 8, 1235, 3745).—

When light illuminated a crystal in one part, there was a change in elec. cond. throughout the whole crystal, and this effect could be transmitted from one crystal to another when they were grown together. The essential difference between the transmitted effect and the direct was that for a given energy intensity the max. effect in the former case occurred at a greater wave length. The action was just as rapid when transmitted 0.5 mm. or 10 mm.; thus it can not be a mere temp. disturbance, for the major portion of the recovery after the light was removed was instantaneous. The elec. cond. may be increased several hundred times by the application of pressure to either lamellar or acicular crystals, but the pressure merely makes it easier for the light to change the cond. and does not act except at the point of application. Since the pressure effect cannot be transmitted, pressure does not increase the cond. by adding free electrons. The extreme variation of cond. with change of potential applied was somewhat greater for higher pressures. The ratio of cond. in the light and dark with different potentials favors the view that the light renders a const. number of electrons in a quasi-stable equil. and the apparent increase in sensibility with higher potentials is the result of pulling out a greater number of semi-stable electrons. A Se crystal may change its resistance along one axis without changing that on a perpendicular axis. This may be explained on the ground that free electrons are not the carriers of current in non-illuminated Se.

E. B. MILLARD.

A qualitative method of investigating thermionic emission. F. L. HOPWOOD. *Phil. Mag.* 29, 362-9(1915).—When an electrified rod, charged with electricity of either sign, is brought near an unlighted 200-v. C-filament lamp, the loops diverge in a manner similar to the leaves of an electroscope, the divergence disappearing on the removal of the charged rod. If a negatively charged rod is brought near the lamp when the filament is glowing, the loops diverge; the effect is also produced by rapidly removing a positively charged rod from the neighborhood of the glowing filament; bringing it near produces no effect. When in the displaced position, the loops respond very readily to the movement of any bodies, whether charged or uncharged. An explanation of these effects is given, based on the passage of ions from the glowing filament to the walls of the bulb until a limiting difference of potential is attained. When the filament is heated above its ordinary temp. by running the lamp above its normal voltage, no effects are produced by bringing a charged body near the lamp. The fact that a glowing filament is attracted by a rod charged with electricity of the same sign as the ions emitted by the filament, etc., is used as a basis of a qual. method of investigating thermionic emission. Metal filaments were tested in air, and in a few cases in H and in CO₂. The following were tested: Fe, Ni, Cu, nichrome (alloy of Ni and Cr), brass, phosphor-bronze, Si-bronze, platinoid, eureka, turned Cu, and galvanized iron. All gave a positive emission.

A. T. CAMERON.

Application of a theory of ionization by impact to the experiments of Franck and Hertz. BERGEN DAVIS. *Phys. Rev.* [2] 5, 118-25(1915).—The theory developed in C. A. 8, 611 has been applied to the expts. described in C. A. 8, 614, 1534. E. B. M.

Ionization by impact. H. W. FARWELL. Columbia Univ. *Phys. Rev.* 5, 149-51 (1915); cf. preceding abst.—Further discussion of the Davis theory. E. B. M.

Foundation of the elementary radiation theory. DAVID HILBERT. *Nachr. K. Ges. Wiss. Göttingen* 1914, 275-98; *Chem. Zentr.* 1915, I, 34-5; cf. C. A. 9, 749.—Mathematical.

E. B. MILLARD.

Electric resolution of series lines in the mercury spectrum. G. WENDT AND R. A. WETZEL. *Phys. Rev.* [2] 4, 549(1914).—In the sharp subordinate series of Hg triplets, no appreciable splitting or displacement of the lines $\lambda\lambda 2925, 2894, 2576$ and $2464 \text{ \AA.}$ was observed. All but $\lambda 2967$ of 8 diffuse subordinate series lines of Hg triplets

showed splitting, or displacements due to the action of the field. Stark's series laws for elec. effect were confirmed. E. B. MILLARD.

Transverse Stark effect upon aluminium doublets. R. A. WETZEL. Aachen. *Phys. Rev.* [2] 4, 550 (1914).—Elec. fields of 50,000 to 90,000 v. per cm. show no appreciable effect upon the doublet $\lambda\lambda 2660-2652 \text{ \AA.}$ of the sharp subordinate series under the dispersion used. In the diffuse subordinate series the line $\lambda 2373$ shows a small displacement towards the red, both in vectors oscillating parallel to the field and perpendicular to it. No effect was produced on $\lambda\lambda 3093-3082$, 2575-2568, or the last line of 2373-2367.

E. B. MILLARD.

A system of wave frequency in the scandium spectrum. EMIL PAULSON. *Physik. Z.* 15, 892-4 (1914); *Chem. Zentr.* 1915, I, 127.—P. indicates several pairs of lines with regularly repeated differences. The differences increase in passing to other elements, e. g., La, with increasing at. wt. E. H.

New type of series in the band spectrum associated with helium. A. FOWLER. S. Kensington. *Proc. Roy. Soc. London (A)* 91, 208-16 (1915).—Preliminary analysis of the spectrum as measured by Curtis (*C. A.* 8, 7) and Goldstein (*C. A.* 7, 3267). Tables are given showing the details of the doublets $\lambda\lambda 4625$, 4648, and the main and 2nd series of doublets. The doublets do not follow the ordinary law of band spectra, but can be arranged in 2 series of the type hitherto exclusively associated with line spectra, and can be approx. represented by the usual formulas involving the Rydberg const. Nine brands of the main series and 4 of the fainter 2nd series have been identified. The 2 series are similar to the principle and diffuse series in line spectra, but the usual relation between such series is not certainly indicated, and no equiv. of the Sharp series has yet been traced. The doublet sepns. are not in accordance with those associated with line spectra; they diminish in passing along the series, but do not vanish at the limit.

E. B. MILLARD.

Influence of molecular constitution and temperature on magnetic susceptibility.
III. Molecular field in diamagnetic substances. A. E. OXLEY. Cambridge. *Proc. Roy. Soc. London (A)* 91, 216-8 (1915); cf. *C. A.* 8, 2524, 3265.—The change of sp. susceptibility accompanying crystn. may be produced by a local mol. field of 10^7 gauss which comes into operation on crystn. This intense local field distorts the mols. and alters the period of vibration of the electrons. The field is of alternating character, the distance over which it is unidirectional being comparable to the distance between mols. The extent of change of the period of vibrating electrons is the Zeeman effect of the local field. The local mol. field must be large in comparison with that producible in the lab. in order to account for the augmented double refraction of the cryst. state. The large potential energy (magnetic) associated with a diamagnetic cryst. structure (expressed in thermal units per g.) is a measure of the latent heat of fusion of the substance. Change of vol. on crystn. may be interpreted as a magneto-striction effect of the mol. field, if its local intensity is 10^7 gauss.

Electromagnetic field in an anisotropic medium. MASSARDI FRANCESCO. *Nuovo cimento* 8, 331-61 (1914).—Mathematical. S. LEVY.

The thermo-electromotive force of certain iron alloys. T. S. FULLER. *Trans. Am. Electrochem. Soc.* 27 (1915) (advance copy).—Most of the alloys in this investigation were melted *in vacuo* or in an atm. of H. The measurements were made against Cu as a standard. The welded joint of each couple served as the hot junction and was placed inside a glass tube closed at the bottom and immersed in boiling H_2O . The cold junctions were placed in melting ice. The zero method of measuring the e. m. f. was used. Of the 9 Fe-Ni alloys tested, 83% Fe gave -0.64 milliv.; 66.5% Fe gave -0.48 ; 18.8% Fe, -2.45 ; 3.2% Fe, -2.00 . Of the 5 Fe-Cr alloys: 90% Fe, 1.20

milliv.; 80% Fe, $+0.43$. The addition of Co to Fe has a very marked effect thermoelectrically: with 10% Co, -0.64 milliv.; 20% Co, -3.70 ; 30% -3.50 . Of the 16 Fe-Ni-Cr alloys tested, 79% Fe, 4% Cr, gave -0.12 milliv.; 35% Fe, 10% Cr, 0.00 ; 25% Fe, 20% Cr, $+0.07$; 20% Fe 25% Cr, -0.08 ; the alloys containing 80 to 90% Ni and the balance Fe and Cr have $+thermo\ e. m. f.$ ranging from 1.00 to 1.70 milliv., whereas pure Ni is -2.38 milliv. For curves and further details see original.

C. G. F.

Initial magnetization as a function of the temperature. P. WEISS AND J. DE FREUDENREICH. *Arch. sci. phys. nat.* 39, 125-48(1915).—W. and F. investigated Fe_2Ni . The curve between the initial susceptibility and the temp. using a const. field of 0.05345 gauss shows a decided max. at 144° when about 10 hrs. is taken to heat the sample from $20-400^\circ$. As the heating is more rapid, the max. is shifted to a lower temp. Quite a detailed study is given to the coeffs. a and b of the relation $k = a + bH$ and a potential relationship is found to exist between the two. The paper is to be concluded.

O. A. RANDOLPH.

Variety of selenium especially sensitive to light. Applications to the construction of selenium cells for photometry. L. ANCEL. *Bull. soc. chim.* 17, 10-4(1915).—Vitreous Se melts at 220° . If this melt is slowly solidified under pressure, there appears another modification of Se which is light gray-violet, formed of very fine crystals extremely sensitive to light, but extremely unstable. These crystals may form a sort of solid soln. on the exterior of the vitreous Se; this is stable and unites the small crystals into a light-sensitive covering over the vitreous Se. Gradual application of both heat and pressure allows the formation of a covering of any desired comp. Great sensibility is observed only when the Se covering is extended to the metal electrodes (generally Cu) between which the Se forms a semi-conductor. It then forms a selenide of the metal which, in the presence of the solid soln., forms a sensitizing agent. The CuSe must be present in very small amt., for if some fine Cu powder was sprinkled on the Se, a melt was obtained which was a good conductor, but which was no longer sensitive to light. Cu was found superior to all other substances for electrodes. Details of expts. using the cell in connection with eclipses of the sun are described.

E. B. MILLARD.

Crystal forms of selenium and some of their physical properties. F. C. BROWN. Univ. Iowa. *Phys. Rev.* [2] 4, 85-98(1914).—A large number of new crystals of Se have been formed, some of which are of great size. All of these forms except one are very transparent selectively to light, a large amt. of light penetrating to a depth greater than 0.2 mm.; all are conducting, with sp. conds. between 200 and 10^7 ; all but one have been observed to be doubly refracting; and all of the forms increase in cond. when illuminated. The action of light is in the Se itself and not in the contacts. Mechanical pressure produces a genuine change in the Se which may alter its cond. more than 1000 times. The absolute change in cond. in one crystal by const. illumination was proportional to the cond. in the dark, when that cond. was altered by pressures between 1 and 180 atms. The temp. at which the crystals sublime in mass has been shown to influence the character of the wave-length sensibility curves. The production of individual crystals of Se of large size opens up a field of investigation which promises to be free from some of the possible complexities of Se cells.

E. B. MILLARD.

Influence of annealing on the characteristics of light-sensitive selenium. E. O. DIETERICH. Univ. Iowa. *Phys. Rev.* [2] 4, 467-76(1914).—The resistance of Se cells depends to a great degree on the treatment to which they have been subjected while annealing them. The location of the max. in the wave-length sensibility curve can be controlled by a variation of the conditions under which the Se in the cell was crystd. In this the temp. variations play the most important part. The various types of cells

can be explained by assuming the presence of various types of crystals or of different positions of the same kind of crystals within the cell; the temp. at which one kind is formed may not be favorable for the formation of another kind, hence the production of the different kinds of cells. E. B. MILLARD.

Acquired radioactivity. SIR WILLIAM CROOKES. *Trans. Roy. Soc. London (A)* 214, 433-45(1914).—A yellow diamond which had served as an anticathode in a vacuum tube for 40 yrs., and which had been subjected to repeated bombardment during that time, was tested to see if the bombardment had conferred radioactivity on it but none could be detected. Negative results were also obtained when other substances, as U glass, and crystals of ruby, garnet and quartz were likewise exposed to the cathode rays. The coloration produced in a diamond exposed to a Ra prep. is due to the α -rays, and the phosphorescence to the β - and γ -rays. The active deposit on a diamond after exposing in a tube of RaBr_2 for 78 days was not removed when heated to 50° in a mixt. of fuming HNO_3 and powdered KClO_3 for 10 days, the acid mixt. being daily renewed. The deposit, however, could be readily removed by grinding the surface of the crystal. W. H. ROSS.

Radioactive content of certain Minnesota soils. J. C. SANDERSON. Univ. Minnesota. *Am. J. Sci.* 39, 391-7(1915).—A detn. was made of the Ra Em and Th Em freely emanated from 13 typical Minnesota soils. The values obtained for the former in terms of the equil. amt. of Ra varied from 13 to 80×10^{-14} g. per cc. of soil; and for the latter in terms of the equil. amt. of Th from 25 to 71×10^{-7} g. per cc. Without exception the very fertile soils were found to be richer in both Ra Em and Th Em than soils of inferior fertility. W. H. ROSS.

The condensation of thorium and radium emanations. A. FLECK. Glasgow Univ. *Phil. Mag.* 29, 337-62 (1915).—When Th Em and Ra Em are mixed with air at atm. pressure, the former appears to be condensed about 5° above the Ra Em. This apparent difference is probably due to the Ra Em in the gaseous phase over the condensed phase being swept away by the air current. As the conc. of the Em in a highly exhausted tube diminishes, the Em becomes more easily condensed. In certain circumstances the condensation curve of Ra Em exhibits 2 maxima, one about -75° , the other about -161° . It is suggested that the existence of this property may be dependent on the presence of H_2O vapor. At liquid-air temp. in a highly exhausted tube, 0.0915% Ra Em remained uncondensed. With a mixt. of the 2 emanations in such a tube, Ra Em appears to be condensed more easily. The difference is probably caused by the rapid disintegration of Th Em. A. T. CAMERON.

The ionization of metals by cathode rays. N. CAMPBELL. Univ. Leeds. *Phil. Mag.* 29, 369-83 (1915).—Expts. described in a recent paper on the ionization of Pt by cathode rays (*C. A.* 8, 3757) have been extended to other metals and to higher speeds of the incident rays. The changes in the ionization (considerable reduction) previously found to take place on heating the Pt can be produced in that metal, and in Cu and Ni, by making the metal one electrode of an elec. discharge in air, O, H or petrol vapor, at about 2 mm. pressure. The changes were greatest in Cu; in Al hardly any change could be produced. The changes seem connected with "spluttering." With regard to this ionization, it would appear that the surface of the metal can be in the following states: (1) state *A*, that of the metal after it has been polished; (2) a series of states *B'* which are produced after the discharge. The ionization in the states *B'* is smaller for all speeds of the incident rays than in state *A*. Of the states *B'*, one *B*, is distinguished because the ionization in that state is greater (for all speeds of the incident rays) than in any other of the states *B'*, and because it can always be reproduced from any of the states *B'* by subjecting the surface to cathode ray bombardment. State *A* cannot be reproduced from state *B* by such treatment. It is uncertain whether the ionization potential in states *B'* is different from that in state *A*; if different, it is lower. It is uncertain whether the speed of the electrons liberated varies with the state of the surface; it does not vary with the metal (in state *A*), nor with the speed of the incident rays. As the speed of rays is increased the ionization produced by them in a metal in the various states *B'* becomes more nearly equal, and less nearly equal to the ionization by those rays in the metal in state *A*. C. suggests that the difference between state *A* and the states *B'* lies in the fact that in the former the metal is covered with a layer of gas, and in the latter it is not. If this is the case the ionization potential of a metal may be less but is certainly not greater than that of H (11 v.). This view however affords no explanation of the difference between the various states *B'*. These differences cannot be due to the presence of the "double-layers" of Seeliger. If such double-layers were formed at all in these expts., it seems that the ionization must take place at the outer surface of them. A. T. CAMERON.

The relation between certain X-ray wave lengths and their absorption coefficients. W. H. BRAGG. Univ. Leeds. *Phil. Mag.* 29, 407-12 (1915).—Figs. are given showing the X-ray spectrum of Rh, given by the (111) planes of calcite, and of Pd and Ag given by the (111) planes of diamond. Each spectrum contains 4 lines, α_1 and α_2 , β and γ . The first 2 in combination compose the strong line which Moseley (*C. A.* 8, 2307) has observed to be given by a great number of substances, and which constitute the principal part of the K series of characteristic radiations. The third is the outer well known constituent of the K series. The fourth is new. The spectra of all 3 metals are of exactly the same kind. From the results with calcite it is calc. that the spacing of the (111) planes is 2.845 Å. U., giving λ equal to 0.613 Å. U. This agrees well with

the value $0.614 \text{ \AA}$. U. previously found by the use of diamond (C. A. 8, 2308). The values of the wave lengths of the 3 spectra are calc. Logarithmic plotting shows that the absorption coeff. by a given absorber is proportional to $(\text{wave length})^3$ rather than $(\text{wave length})^{3/2}$ as required by theory, but the range of wave lengths found is too narrow for an exact deduction.

A. T. CAMERON.

The tracks of the alpha particles in sensitive photographic films. S. KINOSHITA AND H. IKEUTI. Imperial Univ., Tokio. *Phil. Mag.* 29, 420-5(1915); cf. C. A. 5, 241.—A number of photographs are shown of the tracks produced in a sensitive photographic film when it had been previously touched with a needle point smeared with Ra active deposit. When such a plate, after development, is examd. under the microscope the spot of contact is seen to consist of a multitude of radial trails of Ag grains around a circular dark nucleus, the cavity in the gelatin produced by the needle point. There are two sets of trails, the first emerging at the rim of the nucleus and ending very nearly at the circumference of a circle outside the nucleus, thus presenting themselves as a halo, the second spreading out around the nucleus over a wide region with no sharply defined boundary. The latter are all found in the uppermost layer of the sensitive film, and are attributed to the β -rays. The halo is produced by the α -rays by a process similar to that causing the pleochroic haloes seen in minerals such as biotite and investigated by Joly. In magnetic fields no curvature of the trails was observed, but the minuteness of the path under observation might prevent its detection. Numerous cases of deflexions of α -particles in passage through the emulsion are shown in the photographs.

A. T. CAMERON.

The average thorium content of the earth's crust. J. H. J. POOLE. *Phil. Mag.* 29, 483-9(1915).—Expts. supplementing those of Joly (C. A. 7, 23) using the same methods and the same composite rock mixts. The mean results from all the values obtained are: for acid rocks, 2.13×10^{-8} g.; for intermediate rocks, 1.50×10^{-8} g.; and for basic rocks 0.51×10^{-8} g. of Th per g. of rock, the general mean being 1.38×10^{-8} g. per g. of rock. If the results are weighted according to the number of rocks taken in the sample powders used for the analyses, slightly higher figures are obtained, viz., 2.08, 1.60 and 0.56×10^{-8} g. per g. of rock, resp., the general mean being 1.50×10^{-8} g. per g. of rock. The values are obtained from 86 acid, 48 intermediate, and 56 basic rocks.

A. T. CAMERON.

The nature of the large ions in the air. J. A. POLLOCK. Univ. Sydney. *Phil. Mag.* 29, 514-26(1915).—The large ions in the air, discovered by Langevin (*Compt. rend.* 140, 232(1905)), have a mobility which at const. atm. pressure is a function of the relative humidity only. At standard pressure the mobility varies from $1/1280$ when the humidity is 4%, to $1/3440$ when the pressure is that of satn. The ions do not exist in dust-free air, so the picture most readily formed is that of a collection of H_2O mols. surrounding a dust particle, the whole being electrified by the attachment of a small ion, the ion thus affording an example of the adsorption of H_2O vapor at a rigid surface. A thermodynamic argument, based on the relation between mobility and relative humidity, leads to the conclusion that the adsorbed moisture is in the liquid state with a latent heat and d. little different from that of H_2O . The order of magnitude of the diam. of the ion, calc. on usual kinetic theory lines, varies from 3 to 4×10^{-7} cm. according to the atm. conditions.

A. T. CAMERON.

Ionized gases. E. SALLES. *Ann. phys.* [9] 2, 273-346(1914); cf. Townsend, *Trans. Roy. Soc.* 193, 129(1900).—Review, followed by new expts. of high precision in an app. which allowed the use of pressure higher than 1 atm. Using walls of steel, German silver and brass, it was shown that the walls of the surrounding vessel have no influence on the coeff. of diffusion of the ions, confirming the previous results with tubes of steel and tin (Eve, *Phil. Mag.* 19, 657(1910)). The coeff. of diffusion of

ions at atm. pressure has been measured in air, N, CO₂, O and H, and in air and N at higher pressures. A method of detg. k/D , the ratio of mobility to diffusion coeff., has been worked out (cf. Langevin, *C. A.* 7, 3076). When the ionization is produced by γ -rays, the ions do not appear to carry multiple charges. E. B. MILLARD.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Commercial nitrogen fixation. S. PEACOCK. *Trans. Am. Electrochem. Soc.* 27 (1915) (advance copy).—A polemical note. A commercially successful N-fixation process must give as an end product KNO₃, NH₄NO₃ or (NH₄)₂HPO₄; the factory cost must not materially exceed 5 cents per lb. of combined N figured as NH₃. The strongest present competitor is the NH₃ produced as a by-product in the distn. of coal.

C. G. F.

Complications at the anode in the silver coulometer. T. W. RICHARDS AND F. O. ANDEREGG. Cambridge, Mass. *J. Am. Chem. Soc.* 37, 675-93(1915); cf. *C. A.* 9, 559.—Further expts. to test the effect of the anode liquor on the wt. of Ag deposited at the cathode. In this series of expts. the coulometers were so arranged that the access of anode liquor to the cathode was greatly varied. The porous cup models agreed with each other to 0.0004%; the Kohlrausch form (no septum, but a glass dish to catch anode slime) always gave deposits 0.001 to 0.006% higher. By using a permeable alundum (Al₂O₃) cup, or filter paper, distinctly heavier deposits were obtained, which showed that (if weighed before ignition) the deposits contained included mother liquor and excess Ag. A plate of pure Ag immersed in liquid from the anode (obtained by using an alundum cup inside of a porcelain cup and withdrawing liquid from between the 2 cups) gained in wt. 0.62 mg. in 9 expts. The surface was covered with fine brilliant cryst. laminae, probably due to the deposition of Ag. The "complex ion" theory of anode slime formation (cf. *Proc. Am. Acad.* 37, 432(1902)) is again stated to explain the fine dust formed during the disintegration of the anode. The best results were obtained by using a small porous cup coulometer with a highly burnished cathode and pure electrolyte, the deposit being ignited to incipient redness before weighing.

E. B. MILLARD.

Influence of alternating current on electrolysis by a direct current. JNANENDRA C. GHOSH. Calcutta. *J. Am. Chem. Soc.* 37, 733-52(1915); cf. *C. A.* 8, 3760.—In 2 expts. d. c. was passed through a coulometer, then through another coulometer in which a. c. was superimposed on the d. c. For d. c. alone the wts. of Ag were 0.2451 and 0.2873; for a. c. + d. c. the corresponding values were 0.2415 and 0.2904, showing "that there is practically no difference in the amt. of electrolytic decomp. in the 2 cases." In perfectly reversible cells the a. c. has no influence, but in irreversible cells the a. c. greatly increases the current through the circuit. The increase is due to the diminution in the back e. m. f. of polarization.

E. B. MILLARD.

Electroplating with cobalt. H. T. KALMUS, C. H. HARPER AND W. L. SAVELL. *J. Ind. Eng. Chem.* 7, 379-99(1915); *Trans. Am. Electrochem. Soc.* 27 (1915) (adv. copy, 46 pp.).—This paper presents a large amt. of exptl. data. Theoretical considerations are reserved for a separate publication. Several Co solns. were found to be suitable for com. plating. The best ones are: Soln. 1B: 200 g. CoSO₄.(NH₄)₂SO₄.6H₂O in 1 l. of H₂O, d_{15} = 1.053; and soln. 13B, CoSO₄ 312 g., NaCl 19.6 g., boric acid nearly to satn., H₂O 1 l., d_{15} = 1.25. Co plates from these solns. on brass, Fe, steel, Cu, Sn

German silver, Pb, and Britannia metal; deposited under conditions identical with those met with in general Ni-plating practice. The plate is firm, adherent, hard and uniform. The plated articles may readily be buffed; the luster, although brilliantly white, possesses a slightly bluish cast. The elec. cond. of both solns. is considerably higher than that of the standard com. Ni solns., so that, other things being equal, they may be operated at a lower voltage for a given speed of plating. Soln. 1B will plate 4 times as fast as the fastest Ni soln., soln. 13B, 15 times as fast. Plates from both of these solns. on various stock pieces satisfactorily withstood the various bending, hammering and burnishing tests to which com. Ni work is ordinarily submitted. The 2 solns. are remarkable for their throwing power: they readily and satisfactorily deposit Co in the indentations of the work. They can be operated at a high speed without any mechanical stirring. With soln. 13B operating at 150 amp. per sq. ft. a sufficient wt. of Co is deposited in 1 min.; with the best Ni baths it takes 1 hr. at about 10 amp. per sq. ft. to deposit a plate equally satisfactory, i. e., the actual wt. of metal is 1 of Co to 4 of Ni. In spite of the higher cost of Co it is cheaper to plate with Co than with Ni. Heavy deposits from the 2 Co solns. are vastly superior to any that were produced from Ni solns. Practical tests carried out at the Russell Motor Car Co. shops are cited. In every instance the Co-plated wares were superior to the Ni-plated ones. The paper was discussed at great length. MATHERS showed samples of plate of Fe, Cu, Ni, deposited under conditions recommended by K., H. and S. for Co. M. used 147 amp. per sq. ft. for Fe on brass at 24°, time, 2 min.; for Cu plate, 163 amp. per sq. ft., 2 min.; for Ni 170 amp. per sq. ft., 2 min.; for Co 160 amp. per sq. ft., 2 min. Thirty g. boric acid were added to each soln. Ni-Co alloy plate was found to be more resistant to corrosion than Ni in tests made by HOGABOOM. RICHARDS and BAXTER (*Proc. Am. Acad.* 34, 359(1889)) attributed the non-corrosion of Co to the structure of the metal. PROCTOR found that Co-plated Zn was better and cheaper than Ni-plated Zn.

C. G. F.

Formation of metallic alloys by electrolysis. G. BRUNI AND M. AMADORI. *Atti accad. sci. lett. ed arti, Padova* 30, 349 fol.(1913-14); through *Ann. chim. applicata* 3, 147.—Expts. were made on the pairs of metals Cu-Ni, Fe-Ni, Fe-Co, Ni-Co, and mixts. of the 2 metals in each case were obtained by electrolysis. The comp. of the deposits varies as the ratio of the metals in soln. This ratio is practically equal to that in the deposits, when the c. d. and tension at the electrodes are high. When the c. d. and the tension are diminished the deposits contain that metal in larger proportion which is lower in the e. m. f. series. NH_4 salts and NH_3 tend to increase the deposit of Ni in the Cu-Ni alloy. The % of the Ni diminishes on using a rotating cathode. Analogous results are obtained with Cu-Co. The pair Fe-Ni shows more complex phenomena with weak c. d. (0.05 amp. per sq. dm.). Solns. contg. 40-75% Fe give deposits of const. comp. with about 52% Fe, while for solns. of other comp. the deposits vary in comp. with variation of comp. of the soln. Co-Fe mixts. behave in a similar manner; solns. contg. from 33.3-50% Fe give deposits of a const. comp.

S. LEVY.

The preparation of ammonium persulfate. N. KAMEYAMA. *J. Chem. Ind. Tokyo* 17, No. 191; *Chem. Tech. Rept.* 38, 102-3(1914).—In the electrolysis of neutral $(\text{NH}_4)_2\text{SO}_4$ to form $(\text{NH}_4)_2\text{S}_2\text{O}_8$, the soln. should be kept satd. with the former salt. The current efficiency increases with the c. d. at the anode. Room temps. are desirable. HCl , KClO_3 and various CN compds. aid the oxidation in dil. but not in conc. solns.

W. D. COLLINS.

Chemistry in the development and operation of flaming arc carbons. (A correction.)

W. C. MOORE. *Met. Chem. Eng.* 13, 52-5(1915); *Trans. Am. Electrochem. Soc.* 27 (1915) (advance copy); cf. *C. A.* 9, 757.—In a C arc most of the light comes from the incandescent electrode tips. *Flaming arc* carbons contain admixts. of salts which cause the arc proper to become intensely luminous. In cored flame carbons the core hole is filled with a mixt. of C, flame material such as CaF_2 , and a binder. Reliability of the flaming arc is detd. by the constancy of light distribution, the constancy of light flux, the constancy of color and the ability to start with cold points after the carbons have been in use. In general, flaming arcs have very high efficiency. The c. p. depends upon the amt. and kind of flame material; it passes through a max. as we increase the relative amt. of other salt added to CaF_2 . Flaming arcs may be roughly divided into the 2 classes: arcs with a luminous *sheath* and arcs with a luminous *core*. The CaF_2 arc is of the first type; Cr_2O_3 arc is of second. In general, thermo-luminescence, chemical-luminescence and electro-luminescence are all responsible for the emission of light from a flaming arc. Oldenberg's spectroheliographic work (cf. *C. A.* 8, 1052) shows that the band spectra of CaF_2 arise in the sheath of the arc, while the cyanogen bands seen in an ordinary C arc are due to the collision of C and N atoms in the high temp. core of the arc. A long discussion of the paper followed.

W. C. MOORE.

Operating costs of gas-filled tungsten and flaming arc lamps. E. W. TOMPKINS. *Practical Eng.* 19, 396-7(1915).—Twenty amp. 300 w. gas-filled W lamps allow a more flexible operating system, produce more light and cost less to instal and maintain under existing conditions than 465 w. flaming arc lamps. The saving in trimming and patrolling is 45% and the total annual saving is over 4%. Renewal cost favors the W lamp.

W. H. BOYNTON.

Beck's projector arc lamp. W. WEDDING. *Elektrotechn. Z.* 35, 901(1914); *Electrician* 75, 61(1915); see *C. A.* 9, 1153.

C. G. F.

Isolated storage battery plants. BECKMANN AND HEISIG. *Elektrotechn. Z.* 35, 884(1914).—In Berlin 54 storage battery plants connected with the elec. system, having a storage capacity of approx. 14,400 kw.-hr.; are used in place of isolated plants. Eighty installations of this type in Munich have a capacity of 4500 kw.-hr. per day. The batteries are designed to supply the max. demand during peak load and they are charged when energy can be purchased at a low rate from the city supply. Details of costs of the Kaiser Hotel installation shows a total operating, interest and depreciation expense of \$22,008.00 per yr. against \$26,680.00 without battery. This represents a saving of 16.6% of the original cost of battery installation. Now part of the energy is sold due to an excess capacity since metal filament lamps were introduced and a 33 1/4% saving is realized. Insured continuous operation is another point in favor.

U. S., 1,136,483, Apr. 20. L. E. PORTER. Electrolytic diaphragm cell and agitator for electrolyzing ores (e. g., complex ores of Cu and Zn). The ore suspended in CuSO_4 soln. is passed through the anode compartment and the soln. of extd. values is then passed through the cathode compartment.

Brit., 28,629, Dec. 11, 1913. DETTIFOSS POWER CO. and J. H. LIDHOLM. In a furnace for the manuf. of N compds. of carbides, such as calcium cyanamide, the charge is contained within a casing supported on a hearth which can be lowered from the furnace for the charging operations. A finished charge can thus be removed and immediately replaced by a fresh one before the furnace has time to cool. Cf. C. A. 8, 2444.

Brit., 28,630, Dec. 11, 1913. A. HEINZ. In an electrolytic rectifier, an electrode of Pb-Sb alloy surrounding an Al electrode is made of cellular form to allow circulation of the electrolyte.

Brit., 29,156, Dec. 17, 1913. O. C. RUDOLPH. Complex sulfide ores are melted in an elec. furnace to form a mat which is run into a converter and blown for the complete removal of zinc and lead. The fumes from the converter, together with any Zn, Ag, Pb and S volatilized in the furnace, are treated in a wet-condensing plant for the recovery of the metals as sulfites or sulfates. The liquor, after removal of any pptd. Pb salt, is treated in an elec. plant having perforated anodes. After deposition of the Zn, the liquor is returned to the condenser. The residual mat may be worked directly to blister Cu, or it may be used as a flux in the furnace; Cu ores may also be mixed with the original charge to ensure the production of a high-grade mat. The condenser comprizes a series of compartments, the 1st compartment acting as a depositing-chamber, the 2nd being filled with checker-work bricks, and subsequent compartments containing staggered rows of baffle-rods arranged alternately at right angles. Liquor is supplied through a roof or covering of perforated tiles.

Ger., 280,906, Dec. 17, 1913. EUGEN DIETZ. Process of working up into magnesium oxychloride cement the ppt. resulting from the electrolysis with or without diaphragms, of MgCl_2 solns. such as the end lyes of the potash manuf. Cl seps. at the anode, and $\text{Mg}(\text{OH})_2$ seps. at the cathode and, depending upon the time the hydroxide remains in the electrolyte and upon the temp., it is converted into oxychloride. After removal from the cells, the ppts. are freed from adhering moisture in centrifuges or filter presses to such an extent that the MgO and MgCl_2 in the residue are in such proportions, considering the Cl and HCl lost in the subsequent ignition, that the final product has the constitution of magnesia cement. After such preliminary drying the pasty residue is ignited until more or less completely dehydrated. After cooling, a mass remains which consists of MgO and MgCl_2 , which may be worked up with H_2O to make a strong cement.

LOUIS DERR.

New two-color process. G. E. BROWN. *Chem. News* 111, 156(1915).—The Kodachrome process. Two panchromatic plates are exposed, through red and green filters, resp. After the usual development and fixing the Ag image is dissolved out, and the plate which has been exposed behind the red filter is bathed in a green dye, while the other plate is bathed in a red dye. The plates take up the dye in inverse

proportion to the original Ag deposit. After drying, they are bound in register and viewed by transmitted light. For portrait work the flesh tints are very good, and there are no dots or rulings to mar the detail. Retouching is possible, and duplicates can be made by means of an intermediate glass positive, from which duplicates of the original plate are printed.

L. DERR.

H. I. SCHLESINGER.

Experimental inorganic chemistry and electrochemistry in 1914. A. GUTBIER. *Z. angew. Chem.* 28, I, 77-91, 93-111, 113-26, 131-44, 153-60, 173-6(1915).

E. J. C.

Photochemical phenomena in solutions of nitroprusside with thiocyanates and thiosulfates. A. CASOLARI. *Rend. soc. chim. ital.* [2] 5, 294-6(1914).—A soln. of $\text{Na}_2\text{S}_2\text{O}_3$ added to a little newly prepd. nitroprusside soln. and exposed to direct sunlight develops a blue color at once; this is clearly developed with solns. of 0.01 N $\text{Na}_2\text{S}_2\text{O}_3$. The reaction is accelerated by heat and also takes place *in vacuo*. Prolonged action of light decolorizes the lower layers, and a yellow-brown sediment is deposited. In the dark it is decolorized but becomes blue again on exposure to sunlight until the decolorization is complete. With KOH or NaOH the blue soln. becomes green, then yellow and on boiling seps. $\text{Fe}(\text{OH})_3$ and the filtrate gives a reaction for ferrocyanide. Thiocyanate solns. similarly treated with nitroprusside soln. give a blue-violet coloration which is permanent when placed in the dark. The reaction is very slow in the dark but is hastened by the action of heat. It is more rapid *in vacuo* and is accompanied by the evolution of gas. On prolonged exposure the soln. is decolorized with the sepn. of a bluish ppt. Expts. seem to indicate that this ppt. resembles Berlin blue in its properties. The reaction may be obtained with 1 cc. of the thiocyanate at a diln. of 1:10,000.

E. J. WITZEMANN.

Acid sodium borates. J. PONOMAREFF. Göttingen. *Z. anorg. Chem.* 89, 383-92 (1914).—By making use of Tammann's method (cf. C. A. 8, 2971) for inducing spontaneous crystn., P. crystd. mixts. of $\text{Na}_2\text{B}_4\text{O}_7$ and B_2O_3 containing up to 64.5% excess B_2O_3 , and by observing the temp. of the boundary between crystals and glass in mixts. of various compn., detd. the fusion curve of a portion of the system. The m. p. of $\text{Na}_2\text{B}_4\text{O}_7$ was found to be 732° , that of the compound $\text{Na}_2\text{O} \cdot 3\text{B}_2\text{O}_3$, 694° , that of the compound $\text{Na}_2\text{O} \cdot 4\text{B}_2\text{O}_3$, 783° ; the 1:2-1:3 eutectic is at about 10% B_2O_3 and 580° , the 1:3-1:4 eutectic at about 30% B_2O_3 and 658° ; the latter compd. was still the primary phase at the B_2O_3 -richest point detd., 64.5% B_2O_3 and 585° . The cryst. phases could not be sepd. from the glasses and analyzed, so the crystals were detd. by optical means, and a few cryst. details are given. P. concludes, without giving proof, that in the above system an unbroken series of solid solns. is formed.

GEORGE W. MOREY.

Conductivity study of the reaction between calcium nitrate and dipotassium phosphate in dilute solution. W. A. WITHERS AND ALEX. L. FIELD. West Raleigh, N. C. *J. Am. Chem. Soc.* 37, 1091-1105(1915).—A const. conc. of 1 g. per l. of K_2HPO_4 was maintained, and $\text{Ca}(\text{NO}_3)_2$ equiv. to 0 to 500 mg. N per l. was used. From a break in the curve at 120 mg. N per l., the conclusion was drawn that the reaction which obtained at the end of 24 hrs. (practically after 2 hrs.) was $4\text{K}_2\text{HPO}_4 + 3\text{Ca}(\text{NO}_3)_2 = \text{Ca}_3(\text{PO}_4)_2 + 2\text{KH}_2\text{PO}_4 + 6\text{KNO}_3$. A short time after mixing, there occurs another reaction, probably $4\text{K}_2\text{HPO}_4 + 4\text{Ca}(\text{NO}_3)_2 = \text{Ca}_3(\text{PO}_4)_2 + \text{Ca}(\text{H}_2\text{PO}_4)_2 + 8\text{KNO}_3$. This is an unstable condition which exists for about 7 min. after mixing the solns. The concs. of KH_2PO_4 and K_2HPO_4 in the liquid phase were detd. by a cond. titration,

and confirmed the first equation given above. $\text{Ca}_3(\text{PO}_4)_2$ undergoes partial hydrolysis on pptn., and the extent of this hydrolysis was roughly proportional to the conc. of KH_2PO_4 . It was slightly diminished by the presence of excess $\text{Ca}(\text{NO}_3)_2$.

E. B. MILLARD.

Peroxides of the alkaline earth metals. I. E. H. RIESENFELDT AND W. NOTTEBOHM. Freiburg i/Br. *Z. anorg. Chem.* 89, 405-12(1914).—When H_2O_2 is added to an excess of $\text{Ba}(\text{OH})_2$, or when Na_2O_2 is added to an appropriate Ba salt, $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$ is obtained as a silky, white ppt.; when H_2O_2 is added to a cooled Ba salt soln. and NH_4OH added, small, white crystals of *barium peroxide diperoxyhydrate*, $\text{BaO}_2 \cdot 2\text{H}_2\text{O}_2$, are obtained; above 30° , under otherwise the same conditions, $\text{BaO}_2 \cdot \text{H}_2\text{O}_2$, white crystals, with a trace of yellow is obtained; anhydrous BaO_2 could not be prepd., nor could the compd. $\text{BaO}_2 \cdot 10\text{H}_2\text{O}$. When $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$, prepd. similarly to $\text{BaO}_2 \cdot 8\text{H}_2\text{O}$, is allowed to stand in the cold with a large excess of H_2O_2 , *strontium peroxide diperoxyhydrate*, $\text{SrO}_2 \cdot 2\text{H}_2\text{O}_2$, is obtained; treating a conc. soln. of a Sr salt with H_2O_2 and NH_4OH at elevated temp. yields an impure SrO_2 ; pure SrO_2 can be obtained by heating $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$ at 280° . CaO_2 is obtained from dil. solns. above room temp.; below room temp. $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$ forms. CaO_2 can be obtained at lower temp. in conc. solns. $\text{CaO}_2 \cdot 2\text{H}_2\text{O}$ can be prepd. by hydrating CaO_2 ; $\text{CaO}_2 \cdot 2\text{H}_2\text{O}_2$ from a Ca salt and H_2O_2 in the cold. From observations on the color change on heating CaO_2 , it is concluded that 2 modifications exist. II. *Ibid* 90, 371-7(1915).— $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$ heated in O did not lose O appreciably below 220° , but at 273° the decompn. takes place at an appreciable rate, which increases rapidly with temp. Heated in O under high pressure the rate of decompn. was still small; expts. showed that the dissociation pressure of CaO_2 is greater than 190 atms. at 255° . Attempts to form CaO_2 by heating CaO (prepd. by heating $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$ at 315° until completely decompd.) in O at temps. up to 255° and pressures up to 190 atms. failed, confirming the above lower limit for the dissociation pressure of CaO_2 ; the prepn. of CaO_2 on a com. scale is impracticable because of the high pressure required. It is pointed out that the results of Bergius (cf. C. A. 7, 740) refer to CaO dissolved in NaOH-KOH , and that the active O found was probably due to K_2O_2 formed.

GEORGE W. MOREY.

Constitution of some nitrogen and phosphorus compounds. Constitution of elementary phosphorus. G. LEBAS. *Chem. News* 111, 113-4(1915).—A proof that N_2O contains a 3-numbered ring from the theory of mol. vols. The constitution of N_2O_5 is deduced similarly. It is shown that the constitution of elementary P may be explained by a cross linked formula, equiv. to a tetrahedron with a P atom at each corner. It follows that the directions of the valency links are along the edges of the tetrahedron, a view which may be applied to all trivalent atoms, and which permits configuration of the mols. of their compds.

W. H. S.

Hexabromoselenates. A. GUTBIER AND F. ENGEROFF. Stuttgart. *Z. anorg. Chem.* 89, 307-13(1914).—Prepn. of a number of compds. by a method similar to that previously used (cf. C. A. 6, 2367). As in the previous case the compds. were easily decompd. by solvents, especially H_2O , with sepn. of red colloidal Se, and could only be recrystd. from concd. HBr soln. All the compds. are red and anhydrous. *Tetramethylammonium hexabromoselenate*, $(\text{Me}_4\text{N})_2\text{SeBr}_6$, is easily prepd.; *triethylammonium* tends to give an oily reaction product, but cryst. needles can be obtained by working with small amts. and stirring violently, after which the oil can be crystd. by seeding; *tetraethylammonium* behaves similarly; *i-propylammonium* is more stable than any of the above; *dipropylammonium* forms large crystals; *di-i-butylammonium* tends to form an oily mass; *pyridinium* forms a bluish red microcryst. powder; α -*picolinium* seps. easily as bluish red crystals; β -*picolinium* forms a yellow oil which slowly forms dark red glittering crystals.

GEORGE W. MOREY.

Unstable chromium sesquioxide, and corrections of previous work on the heat effect of chromium and aluminium sesquioxides in fusions with sodium peroxide. W. G. MIXTER. *Am. J. Sci.* 39, 295-9(1915).—Corrected value for heat effect of 1 g. of amorphous Cr_2O_3 reacting with Na_2O_2 is 720 cal., instead of the value previously reported. Heating $\text{Cr}(\text{OH})_3$ in a current of H for a day at 420° gives an unstable dark olive green oxide, which changes in O to the stable green oxide. The unstable form glows when heated in a closed tube, and long heating at a temp. below that at which it glows, changes it to the stable oxide. The heat of reaction of unstable Cr_2O_3 reacting with Na_2O_2 is 865 cal., an approx. value, since some of the stable oxide may have been present. New detns. of the heat effect of Al_2O_3 in fusions with Na_2O_2 give higher results than were previously obtained. The difference is in the O given off, little or none having been observed in previous expts. The av. of results obtained when 1 g. of amorphous Al_2O_3 reacts with Na_2O_2 is 539 cal., an approx. value because of the wide variations in the results. W. H. S.

Compounds of chromates and dichromates with mercuric cyanide. D. STRÖMHOLM. Upsala. *Z. anorg. Chem.* 90, 361-70(1915).—The following chromates were prepd. by dissolving the components in H_2O and cooling; all are yellow. The Rb compound, $2\text{Rb}_2\text{CrO}_4 \cdot 3\text{Hg}(\text{CN})_2 \cdot 2\text{H}_2\text{O}$, long needles; Cs compound, $\text{Cs}_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2 \cdot \text{H}_2\text{O}$, needles; crystals of the Na compd. could not be obtained pure, but probably have a formula similar to the above Cs compd.; NH_4 compound, $2(\text{NH}_4)_2\text{CrO}_4 \cdot 3\text{Hg}(\text{CN})_2 \cdot 2\text{H}_2\text{O}$, flakes; methylammonium compound, $(\text{MeNH}_2)_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2$; dimethylammonium compound, $(\text{Me}_2\text{NH})_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2 \cdot 2\text{H}_2\text{O}$, needles (a higher compd. is probably formed, but it could not be isolated); trimethylammonium compound, $(\text{Me}_3\text{NH})_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2 \cdot \text{H}_2\text{O}$; tetramethylammonium compound, $(\text{Me}_4\text{N})_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2 \cdot \text{H}_2\text{O}$; ethylammonium compound, $2(\text{EtNH}_2)_2\text{CrO}_4 \cdot \text{Hg}(\text{CN})_2 \cdot \text{H}_2\text{O}$; the diethylammonium compound, $(\text{Et}_2\text{NH})_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2$, is difficult to prepare pure, and a higher compd. may exist; compds. with Et_4NH and Et_4N could not be isolated; trimethylsulfonium compound, $(\text{Me}_3\text{S})_2\text{CrO}_4 \cdot 2\text{Hg}(\text{CN})_2 \cdot 2\text{H}_2\text{O}$. The following dichromate compds. were prepd.: Cs compound, $\text{Cs}_2\text{Cr}_2\text{O}_7 \cdot \text{Hg}(\text{CN})_2$, long, yellowish red difficultly sol. needles; methylammonium compound, $(\text{MeNH}_2)_2\text{Cr}_2\text{O}_7 \cdot \text{Hg}(\text{CN})_2$, large, reddish brown crystals; trimethylammonium compound, $(\text{Me}_3\text{NH})_2\text{Cr}_2\text{O}_7 \cdot 2\text{Hg}(\text{CN})_2$, long, red needles; tetramethylammonium compound, $(\text{Me}_4\text{N})_2\text{Cr}_2\text{O}_7 \cdot 2\text{Hg}(\text{CN})_2 \cdot \text{H}_2\text{O}$, long, red prisms; the tetraethylammonium compound, $(\text{Et}_4\text{N})_2\text{Cr}_2\text{O}_7 \cdot 3\text{Hg}(\text{CN})_2$, was difficult to prepare, as the hexagonal yellowish red cryst. kernels did not always sep. and probably are metastable; trimethylsulfonium compound, $(\text{Me}_3\text{S})_2\text{Cr}_2\text{O}_7 \cdot \text{Hg}(\text{CN})_2$, long, red needles. The H_2O in the above hydrated compds. seems to be lost continuously rather than in steps and it is probable that a continuous series of solid solns. is formed in each case. GEORGE W. MOREY.

Ferrocyanides and mercuric cyanide. D. STRÖMHOLM. Upsala. *Z. anorg. Chem.* 90, 370(1915).—In addition to the compds. previously described (C. A. 8, 878), the following have been prepd.: Cs compound, $\text{Cs}_3\text{Fe}(\text{CN})_6 \cdot 3\text{Hg}(\text{CN})_2$, small, hexagonal or triangular crystals; trimethylammonium compound, $(\text{Me}_3\text{NH})_3\text{Fe}(\text{CN})_6 \cdot 3\text{Hg}(\text{CN})_2$, tablets of quadratic, rectangular, or hexagonal outline. G. W. M.

Hydrous ferric oxide. W. D. BANCROFT. *J. Phys. Chem.* 19, 232-40(1915).—It is possible to prepare any number of hydrous Fe_2O_3 solns., if the Fe_2O_3 used has different amts. of H_2O in the particles. The colloidal Fe_2O_3 prepd. according to Péan de St. Gilles (*Compt. rend.* 40, 568, 1243(1855)) by boiling dil. $(\text{AcO})_2\text{Fe}$, is sandy and contains little H_2O . That prepared according to Graham (*J. Chem. Soc.* 15, 249(1862)), by dialysis, is gelatinous and more hydrous. The Fe_2O_3 of Graham tends to change slowly into the less hydrous form. The coarser particles of the Péan de St. Gilles oxide, owing to their sandy character, coalesce with less ease and they are peptized more readily after pptn. with HCl or HNO_3 . The ppt. is gelatinous resembling

the Graham oxide. The irreversibility appears to be due to coalescence of the gelatinous particles, rather than to the difficulty of washing out excess precipitant. The coarse particles of the Péan de St. Gilles oxide are less readily attacked by cold acids than the fine particles of the Graham oxide. The yellow color of the hydrous limonites is probably not caused by a hydrous hydrated oxide, and there is no proof that the color is due to the adsorption of an Fe salt, which is a possibility. By heating the Graham oxide with HCl, Fischer obtained both limonite and hematite, which is undoubtedly due to the lack of uniformity of the Graham oxide. Cf. C. A. 8, 3739.

W. H. S.

Complex ions of nickel and cobalt with cyanogen. G. Rossi. Univ. Bologna. *Gazz. chim. ital.* 45, I, 6-10(1915).—When a soln. of a Ni or Co salt is treated with KCN a ppt. sol. in excess KCN is formed. The $\text{Ni}(\text{CN})_2$ and $\text{Co}(\text{CN})_2$ at first formed is dissolved to form complex nickelo- and cobaltocyanides. R. studied the formation of these complexes by following the variations in elec. cond. In dil. solns. of NiCl_2 and KCN the cond. will be due to K, Ni, CN and Cl ions. But by the formation of $\text{Ni}(\text{CN})_2$ because of its low solubility there is a drop in the cond. Little by little as KCN is added the complex ion $\text{Ni}(\text{CN})_n$ is formed and the difference between the observed and calc. values becomes const. From the data the values of n can be deduced. The cond. of 0.0518 g. $\text{NiCl}_2 + 0.02608$ g. KCN (1 mol.) in 100 cc. H_2O was found to be 113.51^{-8} (calc. 159.72^{-8}); with 2 mols. KCN it was 134.41^{-8} (calc. 222.36^{-8}); with 3 mols. 187.70^{-8} (calc. 285^{-8}); with 4 mols. 242.60^{-8} (calc. 347.64^{-8}); with 5 mols. 305.20^{-8} (calc. 410.28^{-8}); with 6 mols. 367.60^{-8} (calc. 472.92^{-8}). Since the difference between the observed and calc. values produced by adding KCN becomes const. with 4 mols. it is deduced that in the case of Ni n is 4 and the complex ion is $\text{Ni}(\text{CN})_4$; the mol. is $\text{K}_2\text{Ni}(\text{CN})_4$. With 0.0520 g. $\text{CoCl}_2 +$ the same KCN soln. under the same conditions the cond. with 1 mol. KCN was 121.96^{-8} (calc. 159.18^{-8}); 2 mols. 129.95^{-8} (calc. 221.82^{-8}); 3 mols. 179.18^{-8} (calc. 284.46^{-8}); 4 mols. 236.65^{-8} (calc. 347.10^{-8}); 5 mols. 293.86^{-8} (calc. 409.74^{-8}); 6 mols. 350.79^{-8} (calc. 472.38^{-8}); 7 mols. 412.81^{-8} (calc. 535.02^{-8}). The difference here becomes const. only when the 6th mol. KCN is added so that the complex ion becomes $\text{Co}(\text{CN})_6$ and the mol. is $\text{K}_4\text{Co}(\text{CN})_6$.

E. J. WITZEMANN.

Compounds of iridium chloride with organic bases. A. GUTBIER. (With D. HOYERMANN.) Stuttgart. *Z. anorg. Chem.* 89, 340-3(1914).—When a soln. of IrCl_4 is evapd. with excess pyridine, and an excess HCl added, a light brown cryst. powder of *pyridinium hexachloroiridate*, Py_2IrCl_6 , seps.; by the slow action of pyridine vapor on dil. HCl soln. of IrCl_4 , the compound $\text{HPy}_2\text{IrCl}_6$, dark reddish brown crystals, was obtained; the latter compd. on standing with pyridine in a desiccator is converted into the compound IrPy_2Cl_6 , which is also obtained by the action of pyridine on an EtOH soln. of IrCl_4 . Quinoline added to an EtOH soln. of IrCl_4 gives the compound $\text{Ir}[\text{C}_8\text{H}_7\text{N}]_2\text{Cl}_4$; α -picoline added to an EtOH soln. of H_2IrCl_6 gives deep red crystals of the compound $[\text{C}_8\text{H}_7\text{N}]_2\text{H}_2\text{IrCl}_6$; by the action of α -picoline on a warm soln. of Na_2IrCl_6 , a yellow powder of the compound $\text{Ir}(\text{C}_8\text{H}_7\text{N})\text{Cl}_4$ was formed.

GEORGE W. MOREY.

Hexachloroiridates. A. GUTBIER AND BERTA OTTENSTEIN. Stuttgart. *Z. anorg. Chem.* 89, 344-51(1914); cf. C. A. 4, 729.—The following compds. were prepd. by adding the chloride of the base to a soln. of H_2IrCl_6 ; they are sol. in H_2O to not very stable solns., and can be recrystd. from HCl soln.; all are anhydrous lustrous crystals. *Tetramethylammonium hexachloroiridate*, $(\text{Me}_4\text{N})_2\text{IrCl}_6$, dark red needles; *benzylmethylammonium*, dark reddish brown needles; *benzylmethylammonium*, blackish brown needles; *tetraethylammonium*, dark brownish red crystals; *benzalethylammonium* seps. as an oil, which crystallizes as broad, deep brown to black needles; *benzylethylammonium*,

broad, black needles; *tripropylammonium* seps. slowly as brownish black crystals; *tri-*i*-butylammonium* seps. slowly as ruby red crystals; *allylammonium*, delicate felted needles; *di-*i*-amylammonium*, blackish brown, delicate leaves and needles; *tri-*i*-amylammonium* forms an oil which crystallizes as blackish brown crystals; *guanidinium*, dark brown leaves; *triphenylguanidinium*, brown, silky needles which could not be recrystd.; *benzalanilinium*, dark reddish brown crystals which could not be recrystd.; *p-chloroanilinium*, blackish brown needles which could not be recrystd.; *m-bromoanilinium*, blackish brown needles; *p-bromoanilinium*, dark reddish brown needles; *tribenzylammonium*, fine, dark red needles; *dimethyl-*o*-toluidinium*, dark red crystals; *pseudo-camidineum*, small, dark brown needles which could not be recrystd.; *β -picolinium*, dark brown needles; *lutidineum*, black crystals, which sep. slowly; *collidineum*, deep black crystals; *piperidineum*, fine, reddish brown crystals; *i-quinolinium*, difficultly sol., long and broad, dark reddish brown needles.

GEORGE W. MOREY.

Hexabromo-osmates. A. GUTBIER AND L. MEHLER. Stuttgart. *Z. anorg. Chem.* 89, 313-33 (1914).—The following hexabromo-osmates were prepd. by adding the bromide of the base to a HBr soln. of Na_2OsBr_6 ; they are easily decompd. by H_2O , and are best recrystd. from strong HBr soln.; all are anhydrous and have a metallic luster. (With O. EDELHAUSER.) *Methylammonium hexabromo-osmate*, $(\text{MeNH}_2)_2\text{OsBr}_6$, dark brown, 6-sided leaves; *dimethylammonium*, small, dark brown crystals; *trimethylammonium*, crystallizes slowly as dark brown octahedra; *tetramethylammonium*, dark brown octahedra, color (Radde's scale) 26b; *benzalmethylammonium*, dark red crystals, color 27e; *benzylmethylammonium*, color 25b; *ethylammonium*, dark reddish brown, 6-sided leaves; *diethylammonium*, dark brownish red tablets containing many inclusions of dark octahedra; *nirosodiethylammonium*, black, triclinic crystals, difficult to crystallize; *triethylammonium*, poorly formed, black crystals; *tetraethylammonium*, dark reddish brown crystals, color 28c; *benzalethylammonium*, dark reddish brown crystals formed from an oil which first seps.; *benzylethylammonium*, dark brown ramified crystals formed from a reddish brown oil; *n-propylammonium*, reddish violet isotropic scales; *i-propylammonium*, delicate brownish black felted needles; *dipropylammonium*, copper red, rectangular quadratic tablets; *tripropylammonium*, dark reddish brown crystals, color 27b; *n-butylammonium*, blackish brown, 6-sided, probably isotropic tablets; *di-*i*-butyl*, dark brown to black, monoclinic crystals; *tri-*i*-butylammonium*, delicate red needles, color 25e; *allylammonium*, seps. slowly as dark reddish brown cryst. powder; *i-amylammonium*, dark brownish red crystals, hard to obtain and easily decompd.; *di-*i*-amylammonium*, dark brownish red to black, glittering, probably tetragonal prisms; *tri-*i*-amylammonium*, dark reddish brown crystals, color 26c; *ethylenediammonium*, black crystals; *propylenediammonium*, bundles of dark violet needles; *guanidinium*, bronze-colored leaves; *triphenylguanidinium*, deep red crystals; *anilinium*, black needles; *methylanilinium*, reddish to black-brown tablets with rhombic outline; *dimethylanilinium*, forms an oil which thickens to a resin-like mass, and yields 6-sided plates on warming with EtOH; *ethylanilinium*, deep black cryst. skeleton; *diethylanilinium* and *i-amylanilinium*, behaves similarly to the above, the 1st giving black lath-shaped crystals and the 2nd black, kernel-like aggregates of pyramidal crystals; *benzalanilinium*, dark reddish brown crystals; *benzylanilinium*, dark reddish brown to black rhombic tablets; *methylbenzylanilinium*, forms an oil which quickly solidifies to black crystals; *ethylbenzylanilinium*, solidifies from an oil as black, apparently monoclinic crystals; *m-chloroanilinium*, dark brown powder, color 29a; *p-chloroanilinium*, brownish black cryst. felt; *1,2,4-dichloroanilinium*, slowly forms black needles; *o-bromoanilinium*, black needles; *m-bromoanilinium*, black crystals; *p-bromoanilinium*, black needles; *benzylammonium*, broad, black plates; *tribenzylammonium*, dark reddish brown crystals, color 26b; *o-toluidinium*, small, silky, birefringent needles; *m-toluidinium*, black-brown

cryst. skeleton; *p*-toluidinium, black, intergrown needles; *dimethyltoluidinium*, aggregates of black leaves and needles; *dimethyl-p*-toluidinium, forms a dark oil which quickly crystallizes as thick black blocks with rounded corners; *1,2,4*-xylylidinium, deep brown intergrown needles; *1,3,4*-xylylidinium, dark brown, distaff-like aggregates of needles, probably rhombic; *1,4,5*-xylylidinium, deep black, opaque needles; *pseudocumidinium*, dark red to reddish brown cryst. powder; *m*-phenylenediammonium, deep black, opaque, lath-like prisms with domes; *1,2,4*-toluylenediammonium, black needles; *1,3,4*-toluylenediammonium, black leaves; *o*-anisidinium, deep black, flat crystals; *p*-anisidinium, deep black monoclinic needles with terminations; *o*-phenetidinium, bronze-colored needles, color 25b; *p*-phenetidinium, large, broad, black leaves, showing fluorescence on the faces; *pyridinium*, dark reddish brown rhombic leaves; α -picolinium, black leaves with slight birefringence, β -picolinium, dark brown cryst. powder, color 25a; *lutidinium*, black, felted needles; *collidinium*, black, triclinic tablets and needles; *piperidinium*, dark brown needles, color 27b; *i*-quinolinium, dark brownish red probably amorphous powder, color 25b.

GEORGE W. MOREY.

Hexachloro-osmates. A. GUTBIER AND L. MEHLER. Stuttgart. *Z. anorg. Chem.* 89, 333-9 (1914).—The following compds. were prepd. from the chloride of the base and Na_2OsCl_6 in HCl soln.; they are all anhydrous, decompd. by H_2O , and can be recrystd. from HCl soln. *Tetramethylammonium hexachloro-osmate*, $(\text{Me}_4\text{N})_2\text{OsCl}_6$, small, reddish yellow octahedra, color (Radde's scale), 3k; *triethylammonium*, forms slowly on careful evapn. as thick, red monoclinic crystals; *tetraethylammonium*, reddish yellow glittering crystals, combinations of cubes and octahedra; *tripropylammonium*, clear, red monoclinic crystals, color 30k; *di-i-butylammonium*, poorly formed, bright, glittering, red crystals, with slight pleochroism, from yellow to orange, color 29i; *tri-i-butylammonium*, large, red, glittering, triclinic crystals, color 30k; *allylammonium*, reddish brown, glittering, rhombic leaves, with a tendency toward twinning, color 28e; *di-i-amylammonium*, orange-yellow, knotty needles with terminations, color 50; *tri-i-amylammonium*, straw-yellow needles, color 5n; *guanidinium*, dark brown, glittering crystals with micaceous structure; *triphenylguanidinium*, yellowish brown cryst. ppt., color 6q; *i-amylanilinium*, orange-red, delicate, felted needles, monoclinic, often showing twinning parallel to the elongation, color 40; *m-chloroanilinium*, reddish brown, glittering, triclinic needles, weakly pleochroic, color 25c; *o*-bromoanilinium, ruby-red, glittering, monoclinic needles, color 28f; *m*-bromoanilinium, reddish brown, much ramified needles, with inclined extinction and slight pleochroism, orange to red, color 27e; *p*-bromoanilinium, long, dark red, rhombic needles, with pleochroism orange to red; *tribenzylammonium*, small, weakly, slightly brownish yellow, rhombic needles, color 70; *pseudocumidinium*, extremely fine, felted, orange-red, rhombic needles, color 4l; α -picolinium, reddish brown, monoclinic crystals, showing slight pleochroism yellow to orange, color 1h; *lutidinium*, broad, yellowish brown, probably monoclinic needles, color 4m; *collidinium*, brown, glittering, monoclinic crystals, color 1i; *piperidinium*, light brownish red, rhombic needles, weakly pleochroic, color 2k; *i*-quinolinium, long, light reddish brown, glittering needles, probably monoclinic, slightly pleochroic, show a slight tendency toward twinning, color 1h.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

The teaching of analytical chemistry. A. C. CHAPMAN. *Analyst* 40, 77-89 (1915).—Annual address of the president, the Soc. of Public Analysts. P. B. D.

General principles governing the complete analysis of minerals and ores. W. R. SCHOELLER. *Analyst* 40, 90-106(1915).—Outline of a scheme of quant. analysis, including a bibliography. P. B. DUNBAR.

Method of estimating the volume of solid matter in muds. W. H. COLEMAN. *J. Soc. Chem. Ind.* 34, 209-10(1915).—The method was devised for detg. the amts. of C_2N_2 in the sol. $((NH_4)_4Fe(CN)_6)$ and insol. (complex double ferrocyanide of Fe and NH_4) form in the muddy liquid obtained in its recovery from coal gas by passage through a mud obtained by adding $FeSO_4 \cdot 7H_2O$ to gas liquor. Finding it impossible to filter off and dry the mud without altering its comp., C. adopted the following procedure: Shake the muddy liquid till well mixed, measure out, let settle and det. the $(NH_4)_4Fe(CN)_6$ in the clear liquid (= A). To another equal portion of muddy liquid add 50 cc. of H_2O , shake well, let settle, and det. the $(NH_4)_4Fe(CN)_6$ in the clear liquid (= B). The total $(NH_4)_4Fe(CN)_6$ contained in the original muddy liquid was detd. (= C). *Calculation:* let x = cc. of liquid in the 50 cc. of mud taken for B before diln.; then as 50 cc. of H_2O was added, $50 + x$ = cc. of liquid in the 100 cc. after diln., and this would contain the same total amt. of ferrocyanide as was contained in the x cc., provided none of the insol. ferrocyanide went into soln. on diln. Then $Ax = (50 + x)B$ or $x = 50B/(A - B)$ cc., or $50 - x$ cc. = vol. of solid matter in 50 cc. of the original mud. If the quantities were weighed out, the wt. of soln. and of dry solid matter would be obtained. *Conditions for accuracy:* Solid matter must be quite insol. and must not be rendered sol. or altered in amt. by diln. The liquid must contain some sol. substance that can be easily detd. and which is not altered by diln.; adsorption must not occur. *Applications:* to vat waste, C_2N_2 liquor, sewage, etc.; and in many cases where an approx. result only is required, a detn. of the decrease in d. after diln. will suffice. To insol. muddy deposits in solns. for crystn.; in vol. analysis to ascertain the vol. of a ppt. when a portion of clear liquid is taken for analysis. To the detn. of naphthalene in creosote by heating latter till quite liquid and then detg. N by Kjeldahl method; cool and let the naphthalene crystallize, filter and det. N in the clear oil; calc. vol. of the deposited material. F. W. SMITHER.

Separation of gold and platinum from other metals. A. CHRISTENSEN. *Z. anal. Chem.* 54, 158-9(1915).—To a weak HCl soln. of the metals add a moderate excess of hydrazine sulfate and let stand in boiling H_2O about 1 hr. (should the mixt. contain Ba or other metals that form insol. sulfates, they can be first removed by pptn. with H_2SO_4 or hydrazine-HCl may be used as the pptnt.). The ppt. may contain Hg and a little Cu besides Au and Pt; all other metals, including As, Sb and Sn are not pptd. Filter off the ppt., wash, and boil with HNO_3 to dissolve Hg and Cu; filter and wash. The filtrate may be examd. separately or mixed with first filtrate. Dissolve the residue of Au and Pt in *aqua regia*, evap. off excess of solvent and in the weak HCl soln. ppt. the Au with SO_2 and then the Pt with NH_4Cl . The filtrate from the hydrazine pptn. can be treated with H_2S and $(NH_4)_2S$ in usual manner. After removing any ppts. by H_2S , $(NH_4)_2S$, or $(NH_4)_2CO_3$, the hydrazine salts may be expelled along with the NH_4 salts by evapn. and ignition. In the method, Au is pptd. as such at once, while $PtCl_4$ is reduced to $PtCl_2$ and finally quant. to Pt on warming. F. W. S.

Determination of platinum, palladium and gold. A. M. SMOOT. *Eng. Mining J.* 99, 700-1(1915).—Scorify the Pb buttons from 2 or more $1/2$ assay ton fusions with

6 times as much Ag as the combined wt. of Pt, Pd or Au, and cupel hot. Part with HNO_3 . Pd goes into soln. The residue which is Au with some Pt, is dissolved in *aqua regia* and set aside as soln. A. Ppt. the Ag from the HNO_3 soln. (containing Ag, Pd and some Pt) with HCl. Pt remains in soln. Scorify and cupel the AgCl which is colored pink by Pd, and part, repeating the process until all Pd is in soln. Unite the filtrates from the AgCl, add them to soln. A, and evap. to dryness. Take up with dil. HCl (1:3) and evap. again, taking up with 5 drops HCl and 40 cc. H_2O , neglecting any AgCl residue. Ppt. Au with 3 g. oxalic acid with boiling, allow it to stand overnight and filter. Scorify the residue with Ag and det. Au in the usual way. To the oxalic acid filtrate add 5 cc. HCl and make up to 150 cc., heat to boiling and ppt. the Pt and Pd with H_2S . Filter, wash the ppt. into the original beaker, and dissolve it with *aqua regia* allowing the acid fumes to dissolve any traces of Pt and Pd remaining on the paper. Evap. the soln. to dryness with HCl to remove HNO_3 , take up the residue with 3 drops HCl and 2 cc. H_2O , add 5–10 cc. of satd. soln. of NH_4Cl , stir and set it away overnight. Ppt. Pt as $(\text{NH}_4)_2\text{PtCl}_6$. Filter and wash with 20% NH_4Cl soln. Pd goes into the filtrate which is set aside as soln. B. Dissolve the Pt ppt. in boiling 5% H_2SO_4 and ppt. with H_2S as before. Burn the filter and proceed as for Pt assay. To soln. B add 7 times as much dimethylglyoxime dissolved in HCl (2:1) as there is Pd present. Dil. to 300 cc., heat on a steam bath for 30 min. and set away overnight. The $(\text{C}_6\text{H}_{14}\text{N}_4\text{O}_4)_2\text{Pd}$ is filtered through a Gooch, washed with dil. HCl, H_2O and EtOH and dried at 110° . It contains 31.686% Pd.

H. L. OLIN.

Volumetric determination of silver. C. DEBRUN. *Ann. fals.* 7, 407–9(1914); through *J. Soc. Chem. Ind.* 34, 251.—In the Gay-Lussac method the detn. of Ag by titration with NaCl soln., 100 cc. of which at 15° is equiv. to 1 g. of Ag, a correction must be applied if the titration is made at another temp. than 15° . D. gives the necessary corrections to be applied to the NaCl soln. in tabular and graphic form. Thus, at 0° , 100 cc. of the soln. will have an apparent vol. of 99.953 cc.; at 5° , 99.938 cc.; at 10° , 99.956 cc.; at 20° , 100.092 cc.; at 25° , 100.205 cc.; at 30° , 100.328 cc.; and at 35° , 100.484 cc.

H. A. LEPPER.

Determination of silver in ores and concentrates containing platinum and palladium. A. M. SMOOT. *Eng. Mining J.* 99, 701(1915).—Make the usual crucible fusion but, instead of cupelling, dissolve the button in dil. HNO_3 . Most of the Ag dissolves, together with Pd and a trace of Pt. Filter and wash the residue, scorify with a little Pb and dissolve the button as before. Combine the filtrates, ppt. the Ag with NaCl and add 2 cc. of conc. H_2SO_4 . Filter off the AgCl and PbSO_4 and scorify with Pb to det. Ag.

H. L. OLIN.

A sensitive iron reaction and a method for the colorimetric estimation of iron. L. CHUGAEV AND B. ORELKIN. Petrograd. *Z. anorg. Chem.* 89, 401–4(1914); *J. Russ. Phys. Chem. Soc.* 46, 1874–6(1914).—A very sensitive test for Fe is given by the characteristic intensely red compd. formed by Fe^{++} with dioximes, e. g., dimethylglyoxime; Fe^{++} compds. may be reduced with hydrazine, an excess of which tends to be beneficial. For the colorimetric estn. of Fe, add to 50–70 cc. of the soln. 1 g. $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ and 5 cc. of a satd. EtOH soln. of dimethylglyoxime, heat the soln. to boiling, add 10 cc. 25% NH_4OH soln., continue the boiling $\frac{1}{2}$ min., cool the soln. rapidly, dil. with H_2O to 100 cc. and compare in a colorimeter with a standard Fe soln. The method permits the detection with safety of 6×10^{-8} g. Fe in 1 cc.; the minimal abs. amt. of Fe detectable is less than 5×10^{-8} g.; quant. the method permits the estn. within 1–2% of the Fe content of solns. 0.0001–0.00005 N. Large amts. of Zn and Al interfere.

GEORGE W. MOREY.

The estimation of potassium by the perchlorate method. R. G. THIN AND A. G. CUMMING. *J. Chem. Soc.* 107, 361–6(1915).—Low results with the HClO_4 method for

K, obtained by Davis (cf. *C. A.* 7, 394), were found to be due to the soln. of KClO_4 in the wash liquid (95% EtOH containing 0.2% HClO_4). The authors found that a freshly prepd. washing soln. of 95% EtOH satd. with KClO_4 gave accurate results. In this detn. NH_4 salts must not be present in quantity but other salts even up to 2 g. of chlorides have no effect. The evapn. with HClO_4 must be carried far enough to insure complete conversion of chlorides into perchlorates. H. L. OLIN.

Examination of litharge. P. BECK. *Z. anal. Chem.* 54, 137-47(1915).—The processes for mfg. PbO are briefly discussed in order to indicate the source of the various impurities (SiO_2 , Fe_2O_3 , Al_2O_3 , CaO , MgO , PbSO_4 , etc.). **Flake litharge:** In most cases Cu is the only detn. required; dissolve 100 g. of material in excess of dil. HNO_3 , ppt. Pb as PbSO_4 , filter, and make filtrate up to 1 l.; take an aliquot of 10, 50, or 100 cc. according to Cu content, add excess of NH_4OH , filter off $\text{Al}(\text{OH})_3$ + $\text{Fe}(\text{OH})_3$, acidify filtrate with dil. H_2SO_4 and electrolyze or ppt. CuS with H_2S . The deposit of Cu, if not pure, is dissolved in a little HNO_3 and any Bi removed with NH_4OH and $(\text{NH}_4)_2\text{CO}_3$ and this filtrate acidified and electrolyzed as before. For very accurate work, a subsequent pptn. with H_2S is necessary. A complete analysis may be made by usual methods using a 10 to 100 g. sample. **Ceramics and glass making:** PbO or Pb_3O_4 should not contain over 0.004% Cu or 0.006% Fe. **Gravimetric detn. of Cu and Fe:** Dissolve 100 g. of material in 750 cc. of H_2O and 80 cc. of HNO_3 (d. 1.40), cool (if PbO_2 is present, add 15 cc. of perhydrol), add 40 cc. conc. H_2SO_4 dild. with 200 cc. of H_2O , cool, filter through a double 18.5 cm. filter into a 1.5 l. dish; treat the ppt. of PbSO_4 with 10 cc. of conc. HNO_3 and 250 cc. of H_2O , filter, receiving filtrate in dish with main filtrate and wash once by filling funnel with H_2O . Evap. filtrate to SO_3 fumes, cool, add 100 cc. of H_2O , filter off PbSO_4 and wash with 1 to 2% H_2SO_4 . Pass H_2S into the warm soln. until cold, let stand 12 hrs., filter into a 750 cc. Erlenmeyer flask and wash the ppt. 3 times with H_2O containing H_2S . Return paper with ppt. to the flask used for the pptn., treat with 50 cc. of hot H_2O , 25 cc. conc. HNO_3 and a few drops of H_2O_2 ; heat on water-bath about 1 hr., filter, wash 3 times with hot H_2O , catching filtrate in a 200 cc. dish; to filtrate add 20 cc. dil. H_2SO_4 , heat till all HNO_3 is expelled. Any traces of PbSO_4 are filtered out and washed with 1-2% H_2SO_4 ; to the filtrate in a 200 cc. Erlenmeyer flask, add an excess of NH_4OH and a few drops of $(\text{NH}_4)_2\text{CO}_3$, heat on water-bath about 2 hrs., filter out any $\text{Bi}(\text{OH})_3$, washing 3 times with cold H_2O . Acidify the filtrate with H_2SO_4 and ppt. CuS with a current of H_2S ; filter and wash as usual, finally igniting and weighing as CuO . To the filtrate from the first H_2S pptn. add 25 cc. of satd. tartaric acid soln., an excess of NH_4OH , and then $(\text{NH}_4)_2\text{S}$; fill the flask (750 cc.) up to the neck with hot H_2O , cork loosely with a cork covered with a filter paper and let stand in a warm place for 12 hrs. Filter off the FeS , wash twice with H_2O + $(\text{NH}_4)_2\text{S}$ and then dry, ash and ignite in a Pt crucible, weighing as Fe_2O_3 . Since both Fe and Cu in most cases must be detd. the grav. is to be preferred to the colorimetric method. A modification of the Lunge colorimetric method (cf. *Z. angew. Chem.* 1896, p. 3) for Fe is executed as follows: 2 g. of a normal PbO of known Fe content and 2 g. of sample are each dissolved in 5 cc. of H_2O + 5 cc. of conc. HNO_3 ; to the hot solns. add 5 cc. of dil. H_2SO_4 , filter and wash the PbSO_4 4 times with hot H_2O , receive the filtrate in the measuring cylinders; add NH_4CNS and compare in usual manner. **Accumulator plates:** The PbO must be of high purity, containing traces only of metals of the H_2S group (especially Cu) and a minimal Fe content. These detns. are made by usual methods. Nitrates must be absent and are tested for by leaching 100 g. of the PbO (or Pb_3O_4) with several portions of hot H_2O , concg. the filtrate, then filtering through double paper and testing with diphenylamine or brucine and conc. H_2SO_4 . The PbO formed in the manuf. of nitrites gives a decided test for nitrites. The Cl content should not exceed 0.05% to determine it; dissolve 100 g. of the PbO in 600 cc. of H_2O and 100 cc. conc.

HNO_3 in a l. flask with shaking, avoiding any heating. Add 150 cc. H_2SO_4 (d. 1.15) to ppt. PbSO_4 , cool, make up to mark, mix, and filter off 700 cc., to which are added 52 cc. of AgNO_3 soln. (0.3333 g. AgNO_3 per l.). Two portions of 250 cc. each of the turbid liquid are measured into Erlenmeyer flasks and heated simultaneously till each soln. is clear; then to one of the flasks add 50 cc. of the above AgNO_3 soln. and to the other 50 cc. of a HCl soln. of same normality (1/311) and note which of the 2 solns. is the more turbid. If the addition of the HCl produces the greater turbidity, the sample contains less than 0.05% Cl ; if the addition of the AgNO_3 causes the greater turbidity Cl is more than 0.05%; same turbidity in each soln. indicates exactly 0.05% Cl . (It is assumed that the sample is practically free of Pb_2O_3 .) *Chemical, color, and varnish industries:* PbO of high purity is demanded; should dissolve to a clear soln. and contain very little insol. matter or metallic Pb . To det. the metallic Pb , rub up 100 g. of the sample with 700 cc. of H_2O and 70 cc. of conc. HNO_3 , added portionwise, avoiding any warming (dil. AcOH may be used instead of HNO_3). When all of the PbO has been dissolved, let settle till clear, and decant or filter. Dissolve the residue of Pb in dil. HNO_3 and det. the Pb electrolytically or gravimetrically. A very pure PbO is required for use in a light, clear varnish; darker products and some driers are made with lower grade article. A practical test is made by heating the PbO with linseed oil to 210° and pouring on glass; should give at once a brittle layer that peels off with the finger nail and yields a clear, yellow soln. with turpentine oil. Only pure PbO should be used in the prepn. of cements, although many manufacturers specify a product containing 10 to 25% of BaSO_4 . Various specifications are issued by the rubber manufacturers for PbO ; however, the higher the PbO content, the greater the working value. B. reports a series of expts. on the same sample of PbO showing the variation of the insol. matter with the amt. and conc. of the HNO_3 used for soln. and recommends the following procedure: rub up 100 g. of the sample with 750 cc. of H_2O and add 80 cc. of conc. HNO_3 ; stir cold till no more PbO dissolves, then boil 30 min. and let stand in a warm place till clear; siphon off supernatant soln., filter through a double paper, wash 6 times with hot H_2O , ignite and weigh. The use of HNO_3 is considered more advantageous than AcOH , since some metallic Pb might escape soln. Should significant amts. of metallic Pb be present, it is detd. as given above. (Cf. C. A. 2, 2767.)

F. W. SMITHER.

Determination of formic and acetic acids and the separation of these acids in very dilute solutions. E. HEUSER. Darmstadt. *Chem. Ztg.* 39, 57-9(1915).—The determination of HCO_2H and AcOH by acidifying with H_2SO_4 and distg. with steam requires too much time for ordinary use, and if the H_2SO_4 be replaced by H_3PO_4 , the results are vitiated by the latter passing over into the distillate. Good results are obtained by passing the vapors through a flask filled with glass beads and heated by a water bath, on their way to the condenser (cf. Wenzel, *Monatsh.* 1897, p. 659). The sample is mixed with 50 cc. of H_2O and 50 cc. of H_3PO_4 (d. 1.2) and distd. at 44° (56 mm. pressure) until the vol. is reduced to 50 cc. A further 50 cc. of H_2O is then added and the mixt. again distd. to a vol. of 50 cc. A current of CO_2 -free air is drawn through the app. during distn. The use of a flask filled with glass beads is also necessary in detg. AcOH by distn. in a mixt. of $\text{H.CO}_2\text{H}$ and AcOH after destroying the former by oxidation with $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 . (Cf. McNair, *Z. anal. Chem.* 27, 398(1888).)

F. W. SMITHER.

Estimation of yellow phosphorus (ENGELHARDT) 17. The microspectroscope in mineralogy (WHERRY) 8.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

The laws of formation and transformation of minerals. A. v. FERSMANN. *Trav. Soc. Nat. Petrograd* 43, 255-73 (1912); *Neues Jahrb. Min. Geol.* 1914, II, Ref. 347-8. —F. prefers the Ostwald law of transformation stages to the Goldschmidt mineralogical phase-rule. The processes of mineral transformation are divisible into 4 types: (1) Mineral *A* changes into mineral *B* without intermediate stages, a mixt. of the two resulting. (2) *A* changes to $A_1, A_2, \dots A_n$, the last being the stable end-species, although intermediate stages may be capable of separate existence. (3) Several of the intermediate states of (2) may form simultaneously. And (4) *A* may show continuous alteration into *B*, all properties showing corresponding continuous variation. The term "mutable" is proposed for such compds. A given mineral may, in consequence of these rules, be stable under certain conditions and unstable in others. E. T. W.

The microspectroscope in mineralogy. EDGAR T. WHERRY. U. S. Nat. Museum. *Smithsonian Misc. Coll.* 65, No. 5, 16 pp. (1915).—W. recommends the use of a Crouch binocular stand fitted with a 37 mm. objective, an Abbe-Zeiss "spectral-ocular" in the right-hand tube and in the other an ordinary low power eyepiece marked on the lower lens at the point where the image of a mineral grain falls when it is visible through the spectroscopy slit; the prism which diverts part of the light into the left-hand tube is withdrawn after the mineral grain has been centered so as to increase the light passing through the spectroscopy. A Welsbach or Nernst lamp is used in preference to sunlight to insure the absence of Fraunhofer lines. Illumination by reflected light is employed except for specimens in thin sections; this gives more intense absorption spectra and permits the exam. of crystals on the matrix, gems in their settings, etc. The scale is adjusted by bringing the 058.9 (589 μ) division of the graduation to the D line shown by a Na flame. This method is especially useful in detg. the genuineness of various gems, in picking out corundum, zircon and garnet from gem gravels, in distinguishing greenockite from other yellow coatings, and in the identification of a number of other minerals. It may be employed to detect the presence of Nd, Pr, Er, U^{vi}, U^{iv}, etc.; and in particular has indicated that the red colors of some garnets are due to Cr and perhaps V. Results of exam. of about 200 minerals with the microspectroscope are given in classified tabular form, followed by an analytical key. The elements causing the colors and absorption bands of some minerals are as yet unknown.

L. W. RIGGS.

Studies on the etched figures of Japanese quartz. SHIMMATSU ICHIKAWA. *Am. J. Sci.* 39, 455-73 (1915).—Illustrations are given of etchings of quartz crystals with 55% HF. The grooves on the edges formed by etching are barely visible to the naked eye and the pits on the faces need low magnification. Different faces of a crystal show varying resistance to the action of the acid, and the extremities at the vertical axis are more quickly dissolved away than at the lateral axes, also those of the + lateral axes more readily than — ones. The resulting form in the etching resembles a trigonal trapezohedron. The etching of spheres of Japanese rock crystal shows figures which det. the axes of the crystals from which the spheres were produced. The etching of basal sections cut perpendicular to the vertical axis of twin crystals reveals the revolved or interpenetrated areas and also the direction of the rotation; this affords an important method for the detn. of a twin crystal. The development of etching

figures at the poles of the vertical axis of a sphere or basal section of a quartz crystal is closely connected with atm. pressure and the temp. and conc. of the solvent, so that precisely concordant results are difficult to produce. Natural etched figures of Japanese quartz are illustrated and described, also a study of vicinal faces accompanied by natural etching on a rhombohedral face. Theoretical figures showing the mol. structure of rock crystal and use of models is described. An appendix gives a sketch of quartz work in Japan, showing that the crystal sculptors are governed by principles which correspond to those developed by the etchings.

L. W. RIGGS.

The system: anorthite-forsterite-silica. OLAF ANDERSEN. *Geophys. Lab. Am. J. Sci.* 39, 407-54 (1915); cf. *C. A.* 3, 2925; 5, 54, 1982, 3213; 7, 755, 760, 1339, 1827, 3255, 3731; 8, 2856, 3543.—This paper deals with that part of the quaternary system $\text{CaO-MgO-Al}_2\text{O}_3\text{-SiO}_2$ in which the comp. of mixts. can be expressed in terms of the components anorthite-forsterite-silica. The expts. were made on artificial mixts. of pure components without fluxes and the heating was done in air under ordinary pressure. The methods used have been described in various previous papers, the results are stated in 5 tables. "The following solid phases were observed and their thermal and optical properties described: anorthite, forsterite, cristobalite, tridymite, clinoenstatite, and spinel. Among the binary mixts. those of anorthite and silica form a simple eutectic system, those of forsterite and silica form a system with an unstable compd., clinoenstatite (MgSiO_3) and those of anorthite and forsterite form no true binary system, as spinel is the primary phase in some of the mixts. In a theoretic discussion the general qualities of some ternary systems without solid soln. are reviewed with reference to temp.-conc. diagrams. The quant. relations of the diagrams are pointed out and types of crystn. curves discussed. As some of the ternary mixts. anorthite-forsterite-silica contain spinel as a primary phase, the relations of the whole system cannot be properly expressed more simply than in terms of the 4-component system $\text{CaO-MgO-Al}_2\text{O}_3\text{-SiO}_2$. After a brief discussion of the spinel field the ternary part of the system is described. The system has 2 quintuple points, one of which is a ternary eutectic, the other an alteration point. Of the boundary curves one is an alteration curve, the others ordinary melting curves. The crystn. curves in different sections of the diagram are discussed. The resorption of forsterite as a result of cooling with equil. between liquid and solid is pointed out. Some cases of crystn. with lack of equil. are also discussed. It is shown how the results may be applied to actual rocks, more especially the olivine-bearing rocks."

L. W. RIGGS.

Zonal structure in synthetic fayalite. H. MICHEL. *Min. petrog. Mitt.* 32, 541-2 (1914).—M. observed zonal structure in pure artificial fayalite, and shows that zonal structure in the olivine group is not necessarily due to variation in Mg content.

A. D. BROKAW.

Contributions on the chemical composition of Russian minerals. K. A. NENADKEVICH. *Trav. mus. geol. acad. sci. Petrograd* 5, 37-56 (1911); *Neues Jahrb. Min. Geol.* 1914, II, Ref. 364-5.—III. **Zinc-dibraunite.** An earthy brown alteration product of a zinc ore-deposit was analyzed, and after subtracting the PbO and PbO_2 found, the comp. of the main portion was calc. as $\text{ZnO} \cdot 2\text{MnO}_2 \cdot 2\text{H}_2\text{O}$. [It is probably a mixt.—ABSTR.] As the mineral braunite belongs to the same class of salts, it is proposed that all members of the class (metamanganites) be called braunites; this particular one is accordingly Zn dibraunite. Chalcophanite is a Zn dibraunite with partial replacement of Zn by Mn. IV. **Copper-gold.** Au of the 2nd generation at Karabash, Kish-tim, Ural Mts., has the comp.: Au 74.33, Ag 4.49, Cu 20.39, insol. 0.26, Fe trace, sum 99.47%; sp. gr. 15.17. V. **Powellite.** Occurs at the Karysch Mine, Yeniseisk, and has the comp. CaO 28.85, MoO_3 71.14%. VI. **Cs-beryl.** Cf. Vernadskii, *C. A.* 5,

1049. The methods of analysis applied to all of these minerals are described in detail.
E. T. W.

The mineralogy of Volhynien. L. IVANOV. *Arb. Ges. Erforsch. Volhynien* 6, 225-32 (1911); *Neues Jahrb. Min. Geol.* 1914, II, Ref. 365-6.—Description of occurrences of topaz, goethite, graphite, and hisingerite are given. The last has the comp. (mean of 3 analyses): SiO_2 36.64, TiO_2 tr., Fe_2O_3 36.88, FeO 5.51, MgO 1.26, CaO 0.83, H_2O 18.57, sum 99.69%. This corresponds to $\text{H}_4\text{Fe}_2\text{Si}_2\text{O}_8 \cdot \text{H}_2\text{O}$, but the material was not entirely pure, containing inclusions of magnetite and rutile. The material is an isotropic gel, showing faint double refraction near magnetite dendrites. The sp. gr. is 2.58.
E. T. W.

Greenockite in the d'Herens Valley, Wallis, Switzerland. G. HIEFLEITNER. *Min. petr. Mitt.* 32, 544 (1914).—This mineral occurs as a film on sphalerite, by the alteration of which it has been derived.
E. T. W.

The supposed vanadic acid from Lake Superior is copper oxide. WALDEMAR T. SCHALLER. U. S. Geol. Survey. *Am. J. Sci.* [4] 39, 404-6 (1915).—Tschermacher (*Am. J. Sci.* [2] 11, 233 (1851)) described a natural occurrence of " VO_3 " in the Lake Superior region. S.'s exam. of a similar specimen shows it to consist of felted masses of minute prismatic crystals so thin that under the highest magnification the black borders of total reflection cover the entire crystal. Chem. tests showed absence of V and only Cu_2O present. Even H_2O was not found, though from the small amt. of the specimen available it may have escaped detection. Comparative chem. tests with hydrocuprite from Penn. gave identical results. Two other recent reports of V oxide minerals are also probably erroneous.
L. W. RIGGS.

Orthoclase containing barium. G. TSCHERMAK. *Min. petrog. Mitt.* 32, 543-4 (1914).—Specimens of sanidine and adularia yielded resp. 1.17 and 0.78% BaO .
A. D. BROKAW.

The chemical composition of aluminous augite. G. TSCHERMAK. Vienna. *Min. petrog. Mitt.* 32, 520-34 (1914).—The comp. of aluminous augite has previously been explained by supposing the presence of an aluminosilicate in isomorphous mixt. with diopside. Boeke showed statistically the analyses of alkali-free aluminous augites including those with up to 5% alkali, considering these to be isomorphous mixts. of the oxides. The projections show, however, that diopside (CaMgSiO_6) is the fundamental compound, while isomorphous mixt. of any or all of the following compds. occur: $\text{MgAl}_2\text{SiO}_6$, $\text{CaAl}_2\text{SiO}_6$ and $\text{Mg}_3\text{Si}_2\text{O}_6$.
A. D. BROKAW.

Anthophyllite from Podoli near Bobrau, Mähren. KARL SCHIRMEISEN. Brunn. *Min. petrog. Mitt.* 32, 512-9 (1914).—S. describes anthophyllite found near the contact of granite and serpentine and suggests its contact metamorphic origin. A somewhat incomplete analysis is given.
A. D. BROKAW.

Analysis of rumpfit. G. TSCHERMAK. *Min. Petr. Mitt.* 32, 542-3 (1914).—As the optical properties of this mineral indicate its identity with clinocllore, a new analysis has been made by T. Panzer, yielding SiO_2 31.31, Al_2O_3 20.07, Fe_2O_3 0.82, FeO 1.36, MgO 33.30, K_2O 0.85, Na_2O 0.39, H_2O 12.87, sum 100.97. This is compared with a typical analysis of clinocllore, both directly and after combining Fe_2O_3 with Al_2O_3 and FeO with MgO , and the compns. found to be quite similar, although the rumpfit contains somewhat more Al_2O_3 and alkalis, and less H_2O , indicating admixture of mica.
E. T. W.

The mineral rumpfit. KARL A. REDLICH. Prague. *Centr. Min. Geol.* 1914, 737-40.—The significance of the presence of this chlorite mineral in the alpine talc deposits having been pointed out by R. and Cornu (*C. A.* 2, 1950) its exact comp. becomes of interest, especially since Tschermak (preceding abst.) has suggested its identity

with clinocllore. Material from 3 localities was analyzed in duplicate by separate analysts, and the results show essential agreement and indicate that rumpfite is a distinct species, composed, according to T.'s theory of the chlorites, of from 2 parts serpentine to 3 amesite to 3 to 7 of each, resp. Other analyses indicate admixts. of sericite, talc, etc., with the rumpfite. E. T. W.

The Fisher, Polk Co., Minnesota, meteorite. GEORGE P. MERRILL. *Proc. U. S. Nat. Mus.* 48, 503-6(1915).—The history and whereabouts of specimens of this fall are given, and the superficial and microscopic features described. The metallic and silicate portions were analyzed separately by J. E. Whitfield, the combined result yielding the bulk comp.: SiO_2 38.70, Al_2O_3 4.39, FeO 16.18, MnO 0.336, NiO 0.204, CaO 1.939, MgO 26.018, chromite 0.708, Fe 9.724, Ni 1.618, Co 0.084, sum 99.901; traces of S and Na were present, but no Ba, Sr, Zr, or K. The sp. gr. = 3.37. The stone is an intermediate chondrite, Ci or Cia of Brezina's classification. E. T. W.

Preliminary note on the meteorites in the Bloemfontein Museum. W. A. DOUGLAS RUDGE. *Trans. Roy. Soc. S. Africa* 2, 211-21(1912); *Neues Jahrb. Min. Geol.* 1914, II, Ref. 378.—Descriptions with partial analyses of specimens from Kroonstadt and Winburg (cf. C. A. 8, 2329). E. T. W.

The iron-ore deposits of eastern and western France. PAUL NICOU. *Iron Coal Trades Rev.* 89, 385-6, 413-4(1914).—Statistical and descriptive. H. L. OLIN.

Molybdenite and wolframite in New South Wales. ANON. *Iron Coal Trades Rev.* 88, 914(1914).—A promising field at Winglebong is being developed.

Wolframite in lower Burma. E. M. LEFROY. *Eng. Mining J.* 99, 684(1915).—A description of the geography of the region, the market for the ores, the geological relations, the mining costs and the output. The wolframite occurs in quartz veins traversing granite, in association with cassiterite, molybdenite, and various sulfides.

E. T. W.

Geologic-petrographic studies in the region of the fracture zone of the Erzgebirge west of Bodenbach. HERMANN MICHEL. *Min. petr. Mitt.* 32, 281-401(1914).—Includes descriptions of occurrence and optical properties, with some discussion of comp. or mode of formation, of the minerals analcite, apophyllite, bronzite, chabazite, fluorite, iddingsite, limonite, natrolite, olivine, pyroxene, scolecite, thomsonite, and zeophyllite; and petrographic descriptions of basalt, gaulteite, glassy basalt, granite-porphyry, leucite-nepheline-tephrite, nepheline-basalt, quartzporphyry, rhönite-basalt (with chem. analysis), sodalite-analcite-phonolite, sodalite-tephrite, amphibolite, and gneiss.

E. T. W.

Analysis of a "bread-crust-bomb" from Santorin. LUISE KICHLER. *Vienna. Min. petr. Mitt.* 32, 265(1913).—The analysis of this volcanic bomb given shows it to be identical in comp. with the ordinary lavas of the island.

E. T. W.

New occurrences of rocks of the alkali series in Timor. H. A. BROUWER. *Batavia. Centr. Min. Geol.* 1914, 741-5; continuation of C. A. 7, 3949.—An alkali-rhyolite is described as to occurrence and microscopic petrography, and a complete analysis by E. W. Morley is given. Norms are calc. from this and the rock found to fall in the sub-rang Pantellerose: II.(3).4.1.4. Two new analyses, less complete, by F. Pisani of other rocks from Timor are also given, and their classification discussed. E. T. W.

Inclusions in the south Styrian basalt tuffs and their minerals. J. SCHADLER. *Graz. Min. petrog. Mitt.* 32, 485-507(1914).—S. describes the mineralogy of the inclusions with optical studies and 6 analyses, one each of olivine, bronzite, Cr-bearing diopside, bombs made up of these 3 minerals, same, altered, hornblende, and pyroxene.

A. D. BROKAW.

Diopside(malacolite)-rock from Mixnitz. J. STINY. Bruck. *Centr. Min. Geol.* 1914, 745-6.—The rock is described petrographically and an analysis given. This is recalcd. according to Becke (*C. A.* 8, 1255) and the relation of the rock to previously described ones discussed.
E. T. W.

Quartzite-schist from the Veitsch and rumpfte-schist from Neuberg. H. MICHEL. *Min. Petr. Mitt.* 32, 175-6(1913).—An analysis of each of the rocks is given.
E. T. W.

Quantitative chemical composition of the Stassfurt salt deposits. M. RÓZSA. Budapest. *Z. anorg. Chem.* 90, 377-86(1915).—A discussion of the comp. of salt deposits of various ages at Adachi Dayà-Busen, from which data it is argued that Ochsenius' bar hypothesis as applied to the explanation of the abnormal thickness of anhydrite layers, is in contradiction to physicochem. principles. R. explains the periodic differentiation between anhydrite and NaCl layers chiefly by climatic variations.
G. W. MOREY.

The investigation of deep-sea deposits. J. JOLY. *Sci. Proc. Roy. Dublin Soc.* 14, 256-67(1914).—A description and working diagram of a hydraulic engine which utilizes the pressure of water prevailing at great depths and which is intended to bore into the soft sediments and oozes on the ocean floor. The machine is constructed with a strong cylinder fitted with a piston and discharges into a receptacle which retains the working substance (water) after it has done its work in the engine which is of the ordinary reciprocating type with the usual directions of the pressures reversed and acting from without inwards. If the receptacle holds 10 l. and the plunger of $\frac{1}{2}$ cm². in area has a stroke of 30 cm., then 666 strokes at a force of 110 kg. (242 lbs.) are possible at a depth of 1000 fathoms. At the rate of one stroke per second, this amounts to the development of about 0.4 h. p. for 11 minutes.
R. L. SIBLEY.

The exhalations of Etna. I. G. PONTE. Univ. Catania. *Atti accad. Lincei* 23, II, 341-7(1914).—The new theory of Brun on the anhydrous state of magmatic gas has opened a vast and new field of exptl. research on volcanic exhalations from the geochem. and geophysical point of view. A volcanic rock raised to the m. p. behaves like lava in its paroxysmal phase; the gases exhaled from it are anhydrous, independent of the geographic position of the volcano and of the petrographic nature of its magma. Deville (1856) said that the nature of the smoke of an active volcano in a given period varies with the distance from the eruptive center. The nature of the exhalations of an active volcano in a given place varies with the time elapsing between the beginning and end of an eruption. The 3 recent eruptions of Etna (1908, 1910, 1911) have permitted observations on the truth of the above generalizations. It was demonstrated that the recent lateral eruptions have a direct relationship with the eruptive chimney and that the central crater is always the center of volcanic manifestations. In 1910 enormous masses of ashes were emitted. The temp. 30 m. below the edge was 85°, but sublimed S at this point showed that the vapors had been above 113°. The ashes showed CaSO₄ 2.40 and NaCl 0.34% and traces of HCl, SiO₂, Mg, Al, KCl, Fe and NH₄ and liquid hydrocarbons. In Sept., 1908, Mt. Rosso was active. CO₂, SO₂, HCl, trace of chlorides and H₂O were found qualitatively in the exhalations. Samples collected near the mouth showed CO₂ 84.5, N₂ 8.2, SO₂ 1.2, H₂S 1.6, H₂ 1.5, CO 2.3 and CH₄ 0.7%; and as a sublimate in the tube the chlorides and fluorides of Na, K and Fe were found. Gas evolved from the flowing lava (600°) showed CO₂ 32.7, N₂ 63.3, SO₂ 3.8%, H₂S, CH₄ and CO in traces, rare gases 0.2%; also fluorides, chlorides and sulfates of Na, NH₄ and Fe in the sublimate. The rivulet of lava had a pasty crust. A blue flame was seen in the tube while the gas was being collected so that it was not analyzed in its unoxidized form. The observations verify the generalizations previously made.
E. J. WITZEMANN.

Mine gases. FRANK HAAS. *Colliery Eng.* 35, 375-9(1915).—New view points on the origin, occurrence and behavior of gases usually found in mines are presented.
C. A. COLE.

The development of continuous countercurrent decantation in cyanidation of slime. W. J. PENTLAND. *Met. Chem. Eng.* 13, 105-7(1915).—A review and general discussion of the subject.
J. S. G.

Grinding ore for cyanidation: A suggested modification for all-slime practice. W. J. PENTLAND. *Met. Chem. Eng.* 13, 205-6(1915); cf. *C. A.* 9, 48.—P. believes that advantages would result by providing sep. treatment for the slime and for the sand with the accompanying concentrate, and combining the 2 portions at some later stage after sand and concentrate had received special treatment. Suggestions are given for a simple arrangement of a plant for accomplishing this.
C. A. NOWAK.

A chart for determining tailings value. W. J. MCCAULEY. *Engineering Min.* 99, 575(1915).—An illustrated description of a chart for the quick solution of the equation usually employed in detg. tailings value in terms of cents per ton of dry pulp. The general form of chart may also be used for the detn. of cyanide in lbs. per ton of dry pulp and is useful in pulp problems.
J. S. G.

Separation of white metal and gunmetal borings. R. H. WALTON AND G. T. BAILEY. *Met. Chem. Eng.* 13, 204(1915).—The small borings pass from bin to a magnetic separator, are picked up by a revolving belt fitted with pockets, and conveyed to a bin above classifiers. From this bin the borings gravitate to classifiers and are sepd. into 3 grades. From bins No. 1 and No. 2 containing the coarse material, the borings gravitate on to a short revolving belt fitted as above and are delivered into a bin over the furnaces and here gravitate to the furnaces. These furnaces are constructed of Fe tubes, one fitting inside the other. The outer one, being several in. larger in diam. than the inner one, is supported by means of brackets to the floor and carries in the intervening space between the 2 tubes a coil of iron pipe with suitable size perforations for heating the walls of the inner tube by gas. The inner tube is revolved and the hot borings and liquid white metal pass into the revolving screens, smaller in mesh than the last classifier, and the liquid white metal mixed with the borings allowed to escape through the screen into an outer vessel surrounding the screen, heated by a gas coil. In this way the white metal does not cool, but collects at the bottom and can be run into molds. The clean borings pass along the screen into a hand truck on wheels; this can be taken to the foundry and the borings smelted and utilized for ordinary gunmetal castings.
C. A. NOWAK.

Problems in copper leaching. L. D. RICKETTS. *Mining Press* 110, 515-9(1915).—A general discussion with specific reference to R.'s experiences with the Ajo ore in S. W. Arizona; (cf. Croasdale, *C. A.* 8, 3409 and following abstr.). Ajo ore is an oxidized chalcocite in a matrix of granite with a large % of secondary quartz replacing feldspar. Ca, Fe and Al are present in sol. form. Cuprite is found in small amts.

only partly sol. in dil. H_2SO_4 . The amt. of Ag is small. The experiences of Croasdale, Saist, Wedge and others, with Ajo ore are given and the following deductions drawn: Dil. H_2SO_4 gives a very high extn. in which time is more important than strength of acid. A max. size of 6 mm. cube permits percolation and the production of a clear soln. with practically no slime. The ore mined at a cost of between \$0.25 and \$0.50 per ton is commercial on a \$0.12 market, even if leached with H_2SO_4 and the Cu pptd. with pig Fe, leading to waste of acid and Fe and the production of an impure cement Cu requiring further treatment. R. gives results of expts. on electrolytic recovery of Cu from leached CuSO_4 with hard Pb anodes and composite anodes of hard Pb and coke. These and the removal of Fe and Al from the sulfate liquor have proved practicable.

J. S. G.

Considerations which govern leaching-plant operation. S. CROASDALE. *Engineering Min. J.* 99, 575-6(1915); cf. C. A. 8, 3409.—A detailed account with tabulated results obtained in leaching Cu ores. The importance of studying the gang even if it is not acid-consuming is emphasized. Conditions of max. yield are discussed.

J. S. G.

Hydrometallurgical treatment of Michigan copper tailings. R. D. LEISK. *Met. Chem. Eng.* 13, 133-4(1915).—The Calumet & Hecla Mining Co. is developing a combination regrinding and leaching treatment for the accumulation of tailings below its great mill on Torch Lake. If successful, the method will probably be applied to all the old mill dumps in the Cu country which can be profitably worked. The process may also solve the problem of treating mine rock in which the Cu is so finely divided and flaky that losses in ordinary milling treatment are excessive. It is planned to complete the leaching treatment in a 91 to 96 hr. cycle. In treating tailings containing 12 to 13 lbs. of Cu per ton it is expected to recover $5\frac{1}{2}$ to 6 lbs. on the tables and from $4\frac{1}{2}$ to 5 lbs. by leaching. The cost of leaching is estd. at about 35 cents per ton, and the recovery upwards of 70%. An accompanying diagram gives the cycle of treatment.

C. A. NOWAK.

Aluminium precipitation at Nipissing. E. M. HAMILTON. *Eng. Mining J.* 99, 568-71(1915).—A discussion of the Al methods of pptn. in use at the Nipissing low-grade mill with a metallurgical and monetary comparison of Zn and Al as precipitants. The paper is an answer to the criticisms of Johnston and of Clevenger (cf. C. A. 8, 892, 3176). Al is not desirable as precipitant in the treatment of all-gold ores. Its use means a saving in fluxes and fuel in melting the ppt. and a saving in cyanide. In estimating the dissolving efficiency of a soln., H. objects to the use of KI as indicator and since double zinc cyanide has no solvent effect on Ag. compds., he recommends titrating the soln. in terms of free instead of "total cyanide."

J. S. G.

Ore-treatment system of Nevada-Douglas Con. Copper Co. A. J. OREM. *Mining Eng. World*, 42, 770(1915).—The sulfide is treated in a digester with HNO_3 to form sulfates of Fe and Cu, and the HNO_3 is regenerated from the NO formed. The digester mass is discharged into a tank and allowed to settle, after which the Fe'' and Cu'' sulfates soln. is decanted to a stock tank; the residue is thoroughly washed. Part of the washings containing small amts. of Cu and Fe'' sulfates are returned to the NO absorption towers, and are later sent to the digester, after proper acidification. The soln. of sulfates in the stock tanks, containing much H_2SO_4 , is applied to mixed ores containing chalcocite and to oxidized calcareous ores, resulting in the reduction of a portion of the Fe'' to Fe' sulfate and an enrichment of the soln. in Cu. The Cu is pptd. on scrap or pig Fe, the soln. being evapd. and the $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ dehydrated in a special drier; the FeSO_4 is ignited in muffles to Fe_2O_3 , the S gases forced through a H_2SO_4 tower and the acid produced either marketed or used in the treatment of oxidized ores. The residual gases are forced through a tower into which a thick pulp is discharged

from a compartment tank actuated by air lifts, and arranged so that oxidized or roasted ore is continuously fed to the app., and the tailings continuously discharged to a replacement tank. The resultant solns. are mixed with the liquors originating in the digesters as they pass to pptn. launders, reducing to some extent the $\text{Fe}_2(\text{SO}_4)_3$. *Advantages claimed:* Regeneration of HNO_3 and of H_2SO_4 , cheap method of evapn. and drying, the means devised for utilizing the mixed gases and the SO_2 arising from the furnaces, Fe_2O_3 obtained is a marketable product. A process is being developed for the electrolytic pptn. of Cu from solns. heavily charged with Fe. F. W. SMITHER.

Mine and smelter of the United Verde Copper Co. C. A. TUPPER. *Mining Eng. World* 42, 717-27(1915).—A detailed description with numerous illustrations. "The ore bodies are in the form of lenticular lenses and occur in a large shear zone of schist and porphyry. The country rock is diorite and the schist is an alteration of this rock. The porphyry is siliceous and is an intrusive in the schist. The ores are mostly chalcopryite, except on the upper levels where considerable amts. of chalcocite, black oxide and other secondary minerals occur." The Cu ore is classified according to the gang rock: (a) most important, termed "iron raw", assays 32-40% Fe, 35-45% S, 4-10% SiO_2 , Cu varies from a low to a high grade ore; there are immense lenses of low-grade FeS_2 enriched along the lines of contact of the schist and porphyry and along intrusions (locally termed "water courses") to com. ore. These ore bodies extend to within 150 ft. of the surface, over which oxide ores occur carrying good values in Au and Ag and small values in Cu. (b) Chalcopryite in a schist gang; these ore bodies extend almost to the surface with but little alteration or enrichment. (c) Ores in a quartz and quartz porphyry gang, extending to the surface as an Fe-stained quartz cropping. Portions of this latter class of ore are so siliceous that it is used for converter flux, as are parts of the oxide ores overlying the pyrites. The capacity of the plant will approach 3,000 tons daily. F. W. SMITHER.

New Anaconda leaching and acid plants. E. P. MATHEWSON. *Eng. Mining J.* 99, 723-7(1915).—A description, with illustrations, of the 2000-ton-a-day leaching plant and its adjunct, the acid plant. The roasting furnaces are of a modified McDougall type. The values will be pptd. from the soln. by scrap Fe. The H_2SO_4 is produced by the chamber process in a 100-ton plant. F. W. SMITHER.

Boron steel. GERHARDT HANNESSEN. Göttingen. *Z. anorg. Chem.* 89, 257-79 (1914).—A detn. of the T-X diagram in the system B-Fe from 0 to 8.5% B by means of thermal analysis and microscopical exam. Many photomicrographs are given. Attempts to prepare the mixts. by the aluminothermic reaction failed, so mixts. were made using Goldschmidt ferroboration fusions in an atm. of H. An attempt to analyze the products by oxidation in a current of O containing H_2O failed; the method used was the Na_2CO_3 fusion method of Wedekind. The liquidus for the system falls from 1522°, the m. p. of Fe, to the eutectic at 1170° and 4% B; from 0 to 1.38% B the primary solid phase is mixed crystals of δ -Fe, from 1.38 to 4% B, of λ -Fe. The solidus falls to 1415° and about 0.28% B; the satd. δ -mixed crystals of this compn. react with the melt with formation of λ -mixed crystals slightly poorer in B; the δ - λ inversion in the iron was found at 1415°. From the eutectic at 4% B the fusion curve rises to a max. at the compn. of the compd. Fe_3B_2 and 1351°, then falls to 1295° at 8.5% B, which is as far as the system was followed; over the whole of the above range Fe_3B_2 is the primary crystn. Both the λ - β Fe inversion (found at 895°) and the β - α inversion (at 800°) are lowered by addition of B; the various thermal effects found in this region are discussed and compared with the corresponding inversions and unmixings in the Fe-C diagram, but the discussion cannot be briefly abstracted. The B steels are strongly magnetic. Chilled reguli containing from 0.125 to 4% B have a hardness of 5-6; slowly

cooled reguli containing from 0.25 to 1% B a hardness of 6-7, the increase in hardness being due to B pearlite; the compd. Fe_3B_2 has a hardness greater than 9. G. W. M.

The influence of coalescence on the properties of steel and alloys. A. PORTEVIN. *J. Iron Steel Inst.* 90, 204-12 (1914); *J. Chem. Soc.* 108, II, 57.—Bronze contg. 16% of Sn, and consisting of the α - and δ -constituents, was heated in a salt bath at 525° for 1 hr., and cooled from 525° to 475° during 5 hrs. After re-heating rapidly to 525° the slow cooling was repeated. The eutectoid structure disappeared, the masses of δ coalescing, and the hardness (Brinell) diminished. The effect on a steel contg. 25% of Sn was less marked. Annealing a eutectoid steel at 700° for 30 hrs. caused coalescence of the pearlite and a great diminution of hardness. A steel contg. 0.50% of C, annealed at 800° for 10 hrs. and very slowly cooled to 700°, showed segregation of the ferrite into parallel bands without coalescence of the pearlite, while annealing for 30 hrs. at 700° brought about coalescence. E. J. C.

The hardening of metals. ROBERT HADFIELD. *Iron Coal Trades Rev.* 89, 670 (1914).—Presidential address read before the Faraday Society. H. L. OLIN.

Hardness of copper-zinc alloys. D. MENEGHINI. Padova. *Ann. chim. applicata* 3, 95-101 (1915).—The values for hardness were calcd. from the formula $\Delta = P/S$, in which P is pressure used and S is surface of the impression made, which equals $\pi D[(D/2)\sqrt{(D^2/4) - (d^2/4)}]$, D and d being, resp., the diams. of the sphere used and of the impression made by it. The values of Δ were 19.4 for pure Cu, 15.9 for pure Zn, and a max. of 72.5 for the alloy contg. 33.65 parts Cu (P was taken at 10.87 kg). The curves of hardness did not give sufficient evidence of the existence of compds. of definite constitution, although the max. of hardness coincides with the comp. Cu_2Zn , but confirmed the idea that the alloys in question are technically useful only to a max. of 40% Zn. S. LEVY.

The binary alloy copper-zinc and the ternary alloy copper-zinc-lead. N. PARRAVANO, with C. MAZZETTI AND R. MORETTI. Univ. Rome and Padova. *Gazz. chim. ital.* 44, II, 475-502 (1914).—Alloys of Cu-Pb and of Zn-Pb are characterized by the presence of a liquid break from 36 to 85% Pb in Cu-Pb and from 0.5 to 96.5% Pb in Zn-Pb. The temps. of invariant equil. with 2 liquids are 962° and 418°, resp.; the eutectic of Cu-Pb coincides practically with that of Pb and of Zn-Pb with 1% Zn. The alloy Cu-Zn is characterized by a notable complexity. The literature on this alloy is reviewed and discussed. 43 alloys were studied carefully and the temp. and duration of sepn. and transformation of the α , β , γ , δ , ϵ and η forms were detd. The data are summarized in the diagram. The m. p. diagram for Zn-Cu differs from those of Shepard and of Carpenter and Edwards only as regards the equil. horizontals at 905°, 838°, 700°, 595°, 545°, and 425°. The duration of these reactions at the temp. indicated was detd. and the character of the horizontals was established in this way. In Guertler's diagram, the allotropic Cu

360° is included as a transformation of η , but Benedicks and Arpi (cf. *C. A.* 9, 260) have shown that this transformation of Zn does not exist. The alloys of Cu-Zn-Pb have a special importance as brasses because of the ease with which they are worked mechanically. The Pb (Guillet, *Rev. métal.* 2, 100; 3, 243) has the effect of diminishing the number and size of the crystals. These alloys are interesting from the theoretical point of view because of the miscibility breaks. Seven series in which the % Pb was 2, 4, 10, 15, 20, 30, and 50, resp., were examd. In the 2% Pb series the Pb remains uniformly distributed throughout the whole mass of the metal. In the 4% Pb series, Pb remains fairly evenly distributed in the alloys rich in Cu, but as the proportion of Cu increases beyond 40% liquation begins and becomes more accentuated as the % of Pb is increased in other series. It may be said that Pb is practically not dissolved in either α or γ (a brass with 60% Cu at ordinary temp. shows α and γ) and the Pb in Pb brasses is simply mixed with the characteristic crystals. This conclusion, drawn from the duration of the arrests, is further confirmed by the results of Carpenter on the influence of the addition of Pb on the critical point at 470° (*Rev. métal.* 10, 457(1913)). The results are confirmed by photomicrographs of 3 alloys with 2% Pb. E. J. WITZEMANN.

The alloys of zinc and manganese. N. PARRAVANO, with U. PERRET. Univ. Paira and Rome. *Gazz. chim. ital.* 45, I, 1-6(1914).—The alloys of Zn with Mn are not known like those of Mn with Cd and Hg. The behavior of Zn with Fe, Ni and Co is known and the compds. FeZn_7 , FeZn_3 , CoZn_4 and NiZn_3 are formed. It was found in the alloys studied (0 to 30% Mn, because of the volatility of Zn) that 2 compds. MnZn_7 and MnZn_3 were formed and the fusion diagram had the same characteristics as that of Zn-Fe. This similarity in the compds. formed is not rare for elements of the same group but different compds. are more frequently found. The expts. of Tammann on Zn-Fe were done at atm. pressure and so are not strictly comparable. An alloy rich in Mn was first prepared and this added in calc. amts. to the proper amts. of Zn to make a total of 100 g. Twenty-three alloys were studied and the m. p. diagram was constructed. The initial temp. of solidification rose in a gentle convex curve from 419° (m. p. of Zn) to 810°, the solidification temp. of the 29.70% Mn alloy. The 1st temp. of arrest was 417-20°; the 2nd 580-90°; 3rd 725-730°; temp. of transformation 260°. The existence of the 2 compds. given above was deduced from the thermal data. The photomicrographs showed crystals of MnZn_7 and MnZn_3 .

E. J. WITZEMANN.

The possibilities in steel construction by the use of high alloy steels. GEO. L. NORRIS. *Iron Coal Trades Rev.* 89, 801(1914).—The addition of V, up to 0.15%-0.20%, to simple C steels is the simplest means of producing steels of high elastic limit without having recourse to excessive heat treatment.

H. L. OLIN.

Heat treatment of steel wire. JOHN F. TINSLEY. *Iron Coal Trades Rev.* 88, 948-50(1914).—A discussion of the effects of various methods of annealing, patenting and tempering on the tensile strength and ductility of wire.

H. L. OLIN.

Internal corrosion of colliery boilers. EDWARD INGHAM. *Colliery Guardian* 108, 1068-9(1914).—A discussion of boiler troubles such as pitting, smooth wasting, furrowing, etc., and of methods for detecting and preventing them.

H. L. OLIN.

The retardation of the oxidation of iron by bases, chromium chloride and chromates. P. ROHLAND. *Elektrochem. Z.* 21, 203-6(1914); cf. *C. A.* 8, 2070.—It is pointed out that wrought Fe, steel, etc., used in reinforced concrete structures is protected by the basic action of the lime in the cement. $\text{K}_2\text{Cr}_2\text{O}_7$ in dil. soln., borax and KOH are also protective.

W. E. RUDER.

Welding. J. F. LINCOLN. *Proc. Am. Inst. Elec. Eng.* 34, 433-8(1915).—Elec. arc welding can be applied to all metals, but the process has not received the attention it deserves. Approximate estimates of costs, partially comparative, are given.

V. H. GOTTSCHALK.

Efficiency of the oxy-acetylene welded joint. A. L. SMITH. *Am. Mach.* 42, 591-3(1915).—A method of testing the welds is described and the results of a series of comparative tests are given.

Brit., 28,410, Dec. 9, 1913. Z. D'AMICO. In forming a protective coating on aluminium, the surface is treated with a soln. of caustic alkali until a thin layer of aluminate is formed, whereupon the surface, without being washed as described in 22,684, 1910 (C. A. 6, 1427), is treated with a soln. containing CuCl_2 or CuSO_4 , chlorides of NH_4 , Fe, Zn, and Sn, K ferrotartrate, and preferably also powdered CaCO_3 and caustic alkali. The coating thereby produced is washed with lime H_2O and warm H_2O and then heated to a temp. of at least 200° . A layer of C may be formed by immersion in a mixt. of oils and balsams and again heating.

Brit., 28,440, Dec. 9, 1913. R. B. CARNAHAN. Ingot iron contains at least 99.8% of Fe, with or without alloying metals such as Cr, Ni, Cu, or V, not more than 0.14% C, Mn, P, Si, and S in the aggregate, and not more than 0.05% O. It is obtained by prolonging the "blow" in a basic Bessemer converter, and subsequently deoxidizing and degasifying in the manner described in 27,201, 1909, and 5,015, 1911 (C. A. 6, 2228). A phosphorized Fe may contain from 0.05 to 0.5% P.

Brit., 28,450, Dec. 9, 1913. R. B. THOMAS, H. S. THOMAS and W. R. DAVIES. Tin,terne, and other metal-coated plates are manufd. by passing the plates separately through a machine comprizing a pickling-bath, a swilling-bath or other swilling-device, a Sn or like pot, a grease-pot, and branning or dusting app., the spaces between the various parts of the machine being occupied by guides, rollers, or other transferring-mechanism which renders unnecessary the employment of hand-labor between the introduction of the plates into the machine and their removal therefrom. Cf. C. A. 8, 3656.

Brit., 28,571, Dec. 11, 1913. R. B. CARNAHAN. In working pure iron by rolling or forging, the operations are arrested while the temp. passes through the zone of non-malleability, which is stated to be roughly between 1000 and 800° .

Brit., 28,593. Dec. 11, 1913. R. B. CARNAHAN. The process of 28,571 (*supra*), for working iron, is extended to Fe and Fe alloys which, while not pure, are substantially free from Mn, C, and O. Cf. C. A. 8, 1561.

Brit., 28,604. Dec. 11, 1913. E. J. HORWOOD. Treating crude ores, slimes, tailings, concentrates, or mixed sulfides to remove sol. salts, then heating to render 1 or more of the sulfides other than ZnS unfloatable, and then submitting them to a flotation or granulation process. In an example, the ore is washed with H_2O , heated to 400° , as described in 1,789, 1909, and subjected to a flotation process at a temp. of $120^\circ F$. Cf. C. A. 6, 1273, 2232.

Fr., addition 18,721, Mar. 22, 1913, to 463,615 (C. A. 8, 2669). THE MADAGASCAR MINERALS SYNDICATE, LTD. Nickel is obtained from the soln. of the sulfates of Mg and Ni, after oxidation and pptn. of Fe, Al, Cr by $CaCO_3$, by means of pulverulent MgO as $Ni(OH)_2$, which is freed from Mg by heating to a dark red to render the NiO insol., and then dissolving out the MgO . The $MgSO_4$ crystg. from the mother liquor is worked up into Na_2S for the sulfide pptn., according to the equation: $MgSO_4 + 2NaCl + 4C = MgCl_2 + Na_2S + 4CO$, or it is converted into MgO with C.

Ger., 281,094, Apr. 20, 1913. F. MEYER and H. KERSTEIN. Reduction of anhydrous metal chlorides which are volatile, or upon the reduction of which volatile intermediate products result, as $SnCl_4$ and $TiCl_4$, by heating them, in admixt. with a flowing supply of H or of an equivalent gas mixt., preferably under pressure.

C. A. ROUILLER.

Terpenes and ethereal oils. O. WALLACH. Univ. Göttingen. CXVII. Isomerism in the thujamenthone series. *Ann.* 408, 163-82 (1915); cf. C. A. 8, 1572.—I. α -Thujamenthone. α -Thujamenthone (A) is obtained by the reduction of isothujone with Na and EtOH and subsequent oxidation with CrO_3 ; purified through the oxime, it b. $209-9.5^\circ$, $d_{15} 0.8915$, $n_D 1.4474$. The oxime (B), large prisms, m. 97° . Semicarbazone, m. 185° . α -Thujamenthol (C), b. $212-4^\circ$, $d_{15} 0.8990$, $n_D 1.4611$. 15 g. (C), warmed with 30 g. $ZnCl_2$ 25 min. at 190° , gave a thujamenthene, b. $163-5^\circ$, $d_{15} 0.8085$, $n_D 1.4503$, also obtained from (C) and dil. H_2SO_4 at 150° . Nitrosochloride, blue, volatile with steam. (With WALTHER LOHSE.) (B), reduced with Na in abs. alc., gave α -thujamenthylamine (*Ann.* 323, 354, (1902)), b. $196-7^\circ$. Hydrochloride, m. 187° . Acetate, m. $106-7^\circ$. Urea, m. 205° . Phenylurea, m. $111-2^\circ$. Trimethylammonium iodide, m. $199-200^\circ$. 12 g. of the HCl salt, in 24 cc. H_2O , treated drop-wise with 6 g. $NaNO_2$ in 20 cc. H_2O , gave (C) and hydrocarbons. II. β -Thujamenthone. By the reduction of isothujone with $PdCl_2$ and H in MeOH (C. A. 5, 3276) β -thujamenthone (D) is obtained, b. $215-6.5^\circ$, $d_{15} 0.8990$, $n_D 1.4511$. Oxime (E), m. $130-1^\circ$. Warmed with 3 cc. AcOH and 6 cc. H_2SO_4 , an iso-oxime is formed, m. 102° . Reduced with Na and $C_6H_{11}OH$ a secondary base is obtained. Oxidized with 1% $KMnO_4$ a hydroxy iso-xime results, m. $148-9^\circ$. (E) was also prepd. by direct reduction of the oxime. Towards the close of the reaction the reduction is hastened by addition of a little dil. HCl. As a by-product an organic base (isothujylamine?) is obtained, b. 207° . Benzole, m. $147-8^\circ$. Urea, m. 160° . Phenylurea, m. $167-8^\circ$. Sulfophenylurea, m. $151-2^\circ$. β -Thujamenthol, b. $216.5-7.5^\circ$, $d_{15} 0.8995$, $n_D 1.4583$. Heated with $ZnCl_2$ 10 min. at 190° it yields a thujamenthene, b. $161-4^\circ$, $d_{15} 0.8100$, $n_D 1.4514$. β -Thujamenthylamine, b. 206.5° , $d_{15} 0.8550$, $n_D 1.4571$. Hydrochloride, m. above 230° , difficultly sol. in H_2O . Acetate, m. $115-6^\circ$. Benzole, m. 112° . Urea, m. 214° . Phenylurea, m. 165° . Sulfophenylurea, m. 183° . Trimethylammonium iodide, m. 230° .

With HNO_2 the amine gives *tertiary thujamenthol* (I), b. 204° , m. 93° . The HO group is loosely bound and is easily split off by warming 1 part alc. and 5 parts dil. H_2SO_4 1 hr. at 110° in a sealed tube, giving a *thujamenthene* (II), b. $164-6^\circ$, d_{21} 0.8100, n_D

1.4466. (II) differs from the 2 menthenes described above by forming a very difficultly sol. *nitroschloride*, m. 108° ; this easily splits off HCl by warming its soln., giving *isothujone oxime*, m. 119° , which upon reduction with Pd and H gave (E). This establishes the constitution of (I) and (II). (D), oxidized with KMnO_4 , gives the same keto-acid, $\text{C}_{10}\text{H}_{18}\text{O}_3$, and dibasic acid, $\text{C}_9\text{H}_{16}\text{O}_4$, as does (A). CXVIII. Transformation products of methylheptanone and related compounds. *Ibid* 183-202.— $\text{Me}_2\text{CHCH}_2\text{CH}:\text{CHAc}$ is reduced by Na and EtOH to *methylheptanol*, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CH}(\text{OH})\text{Me}$, b. 173.5° , d_{20} 0.8155, n_D 1.4198. The satd. ketones from α - and γ -methylheptenones are identical. Reduced with Na and moist Et_2O this gives the above alc. and the *pinacol*, $\text{C}_{12}\text{H}_{24}\text{O}_2$, b. about 300° , b_{14} 170° , m. $43-4^\circ$. Tetrahydro-linalool (Barbier, C. A. 8, 3009), prepd. by the action of EtMgI upon $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{Ac}$, b. $195.5-7^\circ$, d_{20} 0.8280, n_D 1.4335. Warmed to 170° with 3 parts ZnCl_2 0.5 hr. it gave $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CMe}:\text{CHMe}$, b. $162-3^\circ$, d_{20} 0.7490, d_{21} 0.7475, n_D 1.4273. *Nitrosate*, cryst. *Nitrolpiperidide*. The constitution was established by oxidation to $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{Ac}$. The hydrocarbon was also prepd. from $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{Ac}$, $\text{MeCHBrCO}_2\text{Et}$ and Zn, by decomp. the acid, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{C}(\text{OH})\text{MeCHMeCO}_2\text{H}$, splitting off H_2O and CO_2 . Attempts to prep. the unsatd. ketone, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CH}:\text{CMeAc}$, from the nitrosate, failed. $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{Ac}$ and HOBr gave $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CO}_2\text{H}$. *Monobromomethylheptanone*, from 1 mol. $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{Ac}$ and 1 mol. Br in dry Et_2O , b_{14} $94-7^\circ$. Treated with 1 mol. Na in MeOH or shaken 5-6 hrs. with 1.5 mols. of 2% aq. KOH, this gives *heptonylcarbinol*, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{COCH}_2\text{OH}$, b_{12} 90° , d_{20} 0.9160, n_D 1.43196. *Semicarbazone*, m. 170° . *Oxime*, m. 89° . *Sodium bisulfite compound*. *Ozone*, yellow-brown leaflets, m. 117° . *Dibromomethylheptanone*, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{COCHBr}_2$, b_{12} $130-2^\circ$, b_{18} $139-41^\circ$. Shaken with an excess of aq. KOH it gives an unsatd. *octic acid*, $\text{Me}_2\text{CH}(\text{CH}_2)_3\text{CH}:\text{CHCO}_2\text{H}$, b_{12} $122-3^\circ$, d_{20} 0.938, n_D 1.4511. *Silver salt*. *Amide*, m. 153° . *Isopropyl butylketone*, $\text{Me}_2\text{CHCO}(\text{CH}_2)_3\text{Me}$, obtained by reducing $\text{Me}_2\text{CHCOCH}_2\text{CH}:\text{CHMe}$ (Ann. 319, 112 (1901)) with Pd and H, b. $158-9^\circ$, d_{20} 0.816, n_D 1.4113. *Semicarbazone*, m. $110-1^\circ$. *Oxime*, b_{22} $135-7^\circ$. Upon reduction this gives the base, $\text{C}_8\text{H}_{17}\text{NH}_2$, b. $158-9^\circ$; *hydrochloride*, m. $74-5^\circ$; *urea*, m. $136-7^\circ$. *Isopropylbutylcarbinol*, by reduction of the ketone in moist Et_2O with Na, b. $167-8^\circ$, d_{21} 0.820, n_D 1.4249. *Pinacol*, b_{14} $170-5^\circ$, m. $46-7^\circ$. *Methylisopropylbutylenecarbinol*, $\text{Me}_2\text{CHCMe}(\text{OH})\text{CH}_2\text{CH}:\text{CHMe}$, b. $174-7^\circ$, d_{17} 0.849, n_D 1.4486. *Hydrocarbon*, C_9H_{18} , a by-product in the Grignard reaction, b. $146-9^\circ$. Treated with H_2SO_4 an isomeric hydrocarbon is obtained, which gives a *nitrosate*, m. $122-5^\circ$. *Ethylisopropylbutylenecarbinol*, b. $188-91^\circ$, d_{17} 0.850, n_D 1.4521. *Hydrocarbon*, $\text{C}_{10}\text{H}_{18}$, b. $158-61^\circ$. *Ethylisopropylbutylcarbinol*, b. $191-5^\circ$, d_{20} 0.8455, n_D 1.4378. *Hydrocarbon*, $\text{C}_{10}\text{H}_{20}$, b. 155.7° , d_{20} 0.7570, n_D 1.4302. CXIX. Transformation of trimethylethylene into trimethylcyclopentenone. With JOHANNES RECHENBERG and FRITZ RIESNER. *Ibid* 202-211.—*Methyl amylenenitrolacetoacetate*, $\text{MeC}(:\text{NOH})\text{CMe}_2\text{CHAcCO}_2\text{Me}$, prepd. from $\text{Me}_2\text{C}(\text{ONO}_2)\text{C}(:\text{NOH})\text{Me}$ and $\text{AcCH}_2\text{CO}_2\text{Et}$ in EtONa , m. $145-6^\circ$. 10 g. Me or Et ester, boiled 4 hrs. with 100 cc. of 50% KOH, gives *trimethylcyclopentenone*, $\text{C}_8\text{H}_{12}\text{O}$. *Semicarbazone*, leaflets, m. $199-200^\circ$. Reduced with Pd and H, it gives *trimethylcyclopentanone*, b. $164-7^\circ$, d_{18} 0.8829, n_D 1.4336. *Semicarbazone*, m. 209° . *Oxime*, m. 105° . This reaction is probably as follows: The aceto-

acetic ester compd. undergoes the ketone decompn., and the resulting oxime is hydrolyzed to the corresponding diketone which then suffers inner condensation. In order to establish the constitution of the resulting product homologs were prepd. and partially studied. *Ethyl amyleneisotrolmethyloacetate*, m. 153°. *Ethyl derivative*, m. 163°. *Propyl derivative*, m. 166°. If the above Me or Et ester is treated with EtONa , a yellowish brown compound, $\text{C}_{10}\text{H}_{15}\text{O}_5\text{N}$, is obtained, sol. in alkalis with a red color.

C. J. WEST.

Spectrochemical investigations. K. v. AUWERS, A. BOENNECKE, F. KROLL-PFEIFFER AND G. PETERS. Univ. Greifswald and Marburg. *Ann.* 408, 212-84 (1915). —A consideration of the question as to how far spectrochemistry would help to det. the equil. relations between keto and enol forms led to the optical study of series of O-containing C_6H_5 derivs. I. Spectrochemistry of benzene derivatives. An *o*- or *m*-Me group does not change the exaltation of the parent substance but this is regularly increased by a *p*-Me group, varying from 30 to 70%. This difference is so marked that the *p*-deriv. may be distinguished from the *o*- or *m*-derivs. by this means. The earlier established rule that aldehydes have a higher exaltation than the corresponding ketones and acid esters is confirmed by an exam. of homologs. The action of the MeO group is much stronger than that of Me. Here all 3 positions have a higher exaltation than the parent substance, but the *p*-deriv. may be again distinguished because its value is twice that of the original. A further proof of the slight effect of an *o*- or *m*-Me group is seen in the fact that such a group, introduced into an *o*-MeO aldehyde, does not change the $\text{E}\Sigma$ -value. The ethers of aromatic hydroxy aldehydes, ketones and acid esters have a considerably lower exaltation than the parent compds. The Ac compds. have a smaller exaltation than the corresponding Me ethers. The presence of an *o*-HO group causes a marked increase in the exaltation of the parent substance. The above points are illustrated by several tables of compds. The following data are given: *o*- $\text{MeC}_6\text{H}_4\text{CHO}$, b_{111} 195°, d_4^{20} 1.038, n_D 1.54233, n_D 1.54852, n_D 1.56502, n_D 1.57978 at 19°, $\text{E}\Sigma_\alpha$ 0.93, $\text{E}\Sigma_D$ 1.01. *m*- $\text{MeC}_6\text{H}_4\text{CHO}$, b_{115} 195°, d_4^{20} 1.020, n_D 1.53444, n_D 1.54068, n_D 1.55676, n_D 1.57168 at 21.4°, $\text{E}\Sigma_\alpha$ 1.10, $\text{E}\Sigma_D$ 1.18; *p*- $\text{MeC}_6\text{H}_4\text{CHO}$, b_{118} 198-200°, d_4^{20} 1.016, n_D 1.54015, n_D 1.54693, n_D 1.56413, n_D 1.58000 at 16.6, $\text{E}\Sigma_\alpha$ 1.37, $\text{E}\Sigma_D$ 1.47. *o*- $\text{HOC}_6\text{H}_4\text{CHO}$, b_{118} 86, b_{111} 91°, d_4^{20} 1.167, n_D 1.56526, n_D 1.57358, n_D 1.59674, n_D 1.62097 at 19.7°, $\text{E}\Sigma_\alpha$ 1.52, $\text{E}\Sigma_D$ 1.66. *o*- $\text{MeOC}_6\text{H}_4\text{CHO}$, b_{118} 124-5°, d_4^{20} 1.133, n_D 1.55245, n_D 1.55966, n_D 1.57947, n_D 1.59912 at 20.2°, $\text{E}\Sigma_\alpha$ 1.10, $\text{E}\Sigma_D$ 1.21. *o*-Acetoxybenzaldehyde, $\text{AcOC}_6\text{H}_4\text{CHO}$, from 23 g. $\text{OHCC}_6\text{H}_4\text{ONa}$ and 15 g. II. Spectrochemistry of heterocyclic compounds. Cyclopentadiene, furane and thiophene are spectrochem. the same. The depression of the parent substance—the proof is yet lacking for cyclopentadiene—is either decreased or changed into exaltation, depending upon the nature of the substituent; the action of the same substituent in the various parent substances is different in degree. Coumarone and thionaphthene derivs. have nearly the same sp. exaltation. β -Me or MeO groups have no influence, though they act as disturbing substituents in a conjugation. The spectrochem. behavior of the esters of coumarilic acid is not essentially changed by the introduction of a *m*-Me or MeO group. On the other hand the exaltation of the chromenes is depressed if a Me group is introduced into the conjugation between the double bond of the O-containing ring and a double bond of the C₆H₅ ring. Furfurane, d_4^{20} 0.9366, n_α 1.41837, n_D 1.42157, n_β 1.42967, n_γ 1.43668 at 20° , EZ_α —0.97, EZ_D —1.10. α,α -Dimethylfurfurane, b . $93-4^\circ$, d_4^{20} 0.888, n_α 1.43173, n_D 1.43508, n_β 1.44313, n_γ 1.45008 at 21.6° , EZ_α —0.19, EZ_D 0.19. C. J. WEST.

Dinitronaphthylpyridinium chloride and its transformation products. TH. ZINCKE AND FR. KROLLPFEIFFER. Marburg. *Ann.* 408, 285-314 (1915); cf. C. A. 7, 1711, 2207.—1,3-Dinitronaphthyl-4-pyridinium chloride (a), prepd. by heating 1 part finely pulverized $(O_2N)_2C_{10}H_6Cl$, 1 part C_5H_5N and 8 parts EtOH 20 min., filtering hot from the red by-products, and recrystg. from MeOH containing a little concd. HCl, compact, slightly yellow crystals with 1 mol. MeOH, or needles with 1 mol. AcOH, m. 140° (decompn.), sol. in alc. with a yellowish color (probably due to a slight dissociation or hydrolytic decompn.). The decompn. is complete if the dil. HCl soln. is repeatedly concd. to dryness, or if (a) is dissolved in Ac_2O . Chloroplatinate, yellowish white, sinters 220° , m. 260° (decompn.). In the presence of NaOAc or $NaNO_3$ (a) is hydrolyzed into C_5H_5N and $(O_2N)_2C_{10}H_6OH$; the latter reacts with unchanged (a) to give dinitronaphthylpyridinium dinitronaphtholate, obtained in a yield of 20% in alc. soln., deep red leaflets or needles, m. 210° (decompn.). It is decompd. in hot AcOH. 1 part (a) in 100 parts H_2O , satd. with H_2S , gives dinitronaphthyl mercaptan, yellow powder, m. $117-8^\circ$ (decompn.), sol. in NH_3 with a brown color; NaOH gives a brown-red salt, fine clusters. A small amt. of the disulfide is also formed, brown-red powder, sinters 115° , m. 145° (decompn.), insol. in alkalis. In alc. soln. the principal product is dinitronaphthyl sulfide, yellow needles, m. $273-4^\circ$ (decompn.); yield, 90%. Alkalies give a deep blue-violet ppt., which is unstable. If 1 g. (a) in 20 cc. H_2O is treated with 20 cc. of N NaOH and the blue-violet ppt. at once treated with 25 cc. of N HCl, there results a red compound (b), $(O_2N)_2C_{10}H_6NHCH:CHCH:CHCHO$; this is more easily obtained by treating 10 g. (a) in 200 cc. alc. with 50 cc. of 5% EtONa and then decomp. with alc. HCl (yield, 75-80%); small ruby-red prisms with metallic luster from $CHCl_3$, m. 190° (explosive decompn.). Alc. KOH gives a blue-violet soln. HCl in AcOH (exclusion of H_2O) regenerates (a). 2N HCl gives a trace of (a) but principally $(O_2N)_2C_{10}H_6NH_2$ and the aldehyde $C_6H_4O_2$ (*Ann.* 333, 306 (1904)). Long treatment with acetone in the cold, more quickly upon warming, changes (b) into a yellow modification (c), purified by pptn. from $C_2H_5Cl_4$ with EtOH, m. 190° (decompn.). This form is

not as reactive as (b). Alc. KOH gives a blue-violet color, from which soln. HCl ppts. yellow or brown products. HCl-AcOH gives principally $(O_2N)_2C_{10}H_8Cl$. Alcs. change (b) in various ways; probably the end product is the same as from acetone. MeOH gives an *olive-green compound*, m. $170-80^\circ$, changed into (c) by acetone. C_6H_5OH gives a *yellowish brown modification*, m. 170° (decompn.), changed into (c) by acetone. (b) *acetate*, $C_{10}H_8(NO_2)_2N:CHCH:CHCH:CHOAc$, by b. (b) in 4 parts Ac_2O until soln. resulted, yellow, m. $166-7^\circ$ (decompn.); yield 35-40%; alc. KOH sapon. it to (b). Suspended in MeOH, HCl decomps. it into $(O_2N)_2C_{10}H_8NH_2$. *Benzoate*, prepd. by shaking 1 g. (a) in 60 cc. EtOH with 5 cc. of 5% EtONa soln. and 1 cc. BzCl 10 min., yellow powder, m. $170-80^\circ$ (decompn.). *Carbethoxy derivative*, prepd. as above, using $ClCO_2Et$ in place of BzCl, small citron-yellow prisms, m. 180° (decompn.). *Phenylhydrazine compound*, $C_{10}H_8(NO_2)_2NHCH:CHCH:CHCH:NNHPh$ (d), prepd. from an alk. soln. of (a) and $PhNHNH_2$ in alc., black cryst. powder, m. 140° (decompn.), very insol. Alc. HCl decomps. it into $(O_2N)_2C_{10}H_8NH_2$ and $PhNHC_6H_5NCl$. *Oxime*, brownish red scales with green luster, sinter 164° , m. $166-7^\circ$ (decompn.). This is decompd. by HCl-MeOH. *Amine*, $C_{10}H_8(NO_2)_2N:CHCH:CHCH:CHNH_2$ (f), prepd. by treating 5 g. pure (a) in 250 cc. MeOH with 10 cc. of 25% NH_3 , dild. with the same vol. MeOH, brownish violet powder with bronze luster, m. $143-5^\circ$ (decompn.). Alkali liberates NH_3 , upon warming also C_6H_5N . $PhNHNH_2$ gives (d). *Hydrochloride*, golden orange leaflets, decompd. by H_2O , but sol. in dil. HCl. *Chloroplatinate*, red. *Nitrate*, red powder, somewhat more stable than the chloride. AcOH decomps. it into NH_3 , $(O_2N)_2C_{10}H_8OH$ and the dinitronaphthylate. Ac_2O and BzOH give the corresponding derivs. of $(O_2N)_2C_{10}H_8OH$. *Dinitronaphthol benzoate*, yellow needles, m. 174° . HCl decomps. (f) into C_6H_5N , NH_3 , $(O_2N)_2C_{10}H_8NH_2$ and regenerates a small amt. of (a). If an AcOH soln. of (f) is allowed to stand 1 hr., or if a soln. in C_6H_6 is boiled 3 hrs. the *secondary amine*, $[C_{10}H_8(NO_2)_2N:CHCH:CHCH:CH]_2NH$, is formed, fine black powder, which forms dark brown scales when boiled with H_2O , m. $195-200^\circ$ (decompn.). Conc'd. HCl or H_2SO_4 gives a deep blue soln. *Methylamine derivative*, black-green aggregates, m. $123-5^\circ$ (decompn.). It behaves like the amine. *Hydrochloride*, light red needles. *Dimethylamine derivative*, black scales with green luster, m. $178-180^\circ$ (decompn.). *Hydrochloride*, dark red scales with metallic luster. C. J. W.

Dinitronaphthylisoquinolinium chloride and its transformation products. TH. ZINCKE AND FR. KROLLPFEIFFER. Marburg. *Ann.* 408, 314-39(1915); cf. preceding abstr.—1,3-Dinitronaphthyl-4-isoquinolinium chloride (A), prepd. by boiling a mixt. of 10 g. finely pulverized $(O_2N)_2C_{10}H_8Cl$ in 100 cc. EtOH and 5 g. isoquinoline 1 hr., filtering hot, washing the product with cold MeOH, and pptg. with Et_2O , seps. from MeOH- Et_2O containing a little conc'd. HCl in small compact prisms, sinters 100° , m. $160-5^\circ$ (decompn.). The solns. are somewhat yellow because of dissociation. *Nitrate*, small needles, m. 170° (decompn.). In the presence of AcONa or $NaNO_3$ (A) is decompd. into $(O_2N)_2C_{10}H_8OH$, isoquinoline and HCl. *Dinitronaphthylisoquinolinium dinitronaphtholate* (B), small brick-red needles, m. 205° (decompn.). In H_2O , H_2S gives $(O_2N)_2C_{10}H_8SH$ and $[(O_2N)_2C_{10}H_8S]_2$; in alc. $[(O_2N)_2C_{10}H_8]_2S$. *Pseudo or carbinol base* (C), $(O_2N)_2C_{10}H_8N:CH:CH.C_6H_4.CHOH$, prepd. by treating 5 g. (A) in 250

cc. H_2O with 30 cc. of 2 N Na_2SO_3 , dark brown amorphous powder, sinters 165° , m. 200° (decompn.). Dil. acids dissolve it, forming (A). Heated with H_2O for some time it is decompd., giving (B). Heated with Ac_2O $C_9H_7N.O.C_{10}H_8(NO_2)_2$ (D) is formed. *Methyl ether* (E), by boiling (C) with MeOH, dark red needles, m. 160° (decompn.). Boiled with Ac_2O (D) is formed. *Ethyl ether*, small, brownish violet leaflets with slight metallic luster, m. 150° (decompn.). *Isobutyl ether*, nearly black, m. 118° (decompn.). *Anhydro base hydrochloride*, $C_{38}H_{25}O_9N_4Cl$, obtained as a light red powder, insol. in dil.

HCl, when (C) is extd. with HCl, m. 110° (decompn.). Conc'd. HCl gives (A). MeOH-NH₃ gives (E). Alc. in a sealed tube forms (B). Ac₂O gives (C) and C₉H₇N.O.C₁₀H₄(NO₂)₂. (A) reacts with PhNH₂ and *p*-MeC₆H₄NH₂ to give the corresponding derivs. of (O₂N)₂C₁₀H₄OH. The carbinol base and its ethers react to give the isoquinoline derivs. In the case of MeNH₂ or EtNH₂ both (A) and (C) react in the same way, (O₂N)₂C₁₀H₄NH₂ pptg. and the soln., after acidifying with HCl, containing the alkylisoquinolinium chloride. *Dimethylpseudoammonium base*, prep'd. by adding 4 cc. of 33% Me₂NH to 1 g. (A) in 20 cc. MeOH, deep bluish dark scales, m. 155° (decompn.). Dil. acids change it to (A). Alcs. give the ethers. If (A) is boiled with Me₂NH, (O₂N)₂C₁₀H₄NH₂ is formed. The decompn. of the pseudo base is probably simply a hydrolytic process. 10 g. (A) in 200 cc. warm alc., treated with a mixt. of 10 g. PhNHNH₂ in 10 cc. alc., gives the *phenylhydrazine compound*, (O₂N)₂C₁₀H₄NHCH:CHC₆H₄CH:NHNHPh, brown-red scales with a golden luster, m. 145° . Alc. HCl decomps. it into (O₂N)₂C₁₀H₄NH₂ and C₉H₇N(NHPh)Cl. By the action of Na₂CO₃ upon C₉H₇N(NHPh)Cl, there is formed a *reddish brown compound* (F), probably C₉H₇N:NPh. *Anilinoisoquinolinium pseudocyanide*, PhNHN.CH:CH.C₆H₄CHCN, ob-

tained by adding an excess of KCN to C₉H₇N(NHPh)Cl in 50 parts H₂O, nearly colorless needles, m. 110° . AcOH splits off HCN, giving the acetate. In MeOH KCN splits off PhNH₂, giving *isoquinaldinic nitrile*, also obtained by the action of KCN upon (F), felt-like needles, m. 93° . Conc'd. H₂SO₄ gives the amide (Reissert, *Ber.* 38, 3428 (1905)).

C. J. WEST.

Bromination of aromatic amines. WALTER FUCHS. Univ. Vienna. *Monatsh.* 36, 113-41 (1915).—The bromination of aromatic amines is best carried out in AcOH. The number of Br atoms entering the comp'd. depends upon the conditions of expt. The directing influence of the NH₂ group is stronger than that of any other group. 5 g. *p*-MeC₆H₄NH₂ in 20 cc. glacial AcOH, treated with 46 cc. of a Br soln. (50 g. Br in 200 cc. glacial AcOH), gave 17 g. of the HBr salt and 13 g. 4,2,6-MeBr₂C₆H₂NH₂, m. 79° . 5 g. *p*-H₂NC₆H₄NHAc in 20 cc. AcOH is treated with 5 g. AcONH₄ and 43 cc. Br soln., giving 10 g. *dibromoacetylphenylenediamine*, needles, m. 239° (decompn.). Upon sapon. this gave 3,5-Br₂C₆H₂(NH₂)₂, m. 138° ; diazotized and treated with CuBr, 3,4,5-Br₃C₆H₂NH₂, m. $118-9^{\circ}$, is formed, while if it is diazotized according to Witt (K metabisulfite and conc'd. HNO₃) and poured into alc. CuSO₄, it gives 3,5-Br₂C₆H₂NHAc, m. 231° . Treated with 1 mol. Br in AcOH it gives 3,4,5-Br₃C₆H₂NHAc, m. $255-6^{\circ}$. 5 g. *p*-H₂NC₆H₄Ac in 220 cc. AcOH, treated with 48 cc. Br soln., gave 11 g. *methyl 4-amino-3,5-dibromophenyl ketone*, prisms, m. 180° . *Hydrazone*, golden yellow needles, m. not sharply 146° , cannot be recrystd. Diazotized with conc'd. HNO₃ as above, it yields 3,5-*dibromoacetylphenone*, needles, m. 66° , which is oxidized to 3,5-Br₂C₆H₂CO₂H, m. 209° . *p*-H₂NC₆H₄SO₃H reacts very slowly with Br in the cold, while if the soln. is warmed, *s*-Br₂C₆H₂NH₂ is the principal product. H₂NC₆H₄SO₂NH₂ and Br give 3,5-*dibromosulfanilic amide*, small leaflets, m. 237° . Heated 1 hr. with 75% H₂SO₄ it yields 2,6-Br₂C₆H₂NH₂, m. 83° . 5 g. *p*-H₂NC₆H₄OEt in 15 cc. AcOH, treated with 47 cc. Br soln., and distd. with steam, gave 4 g. 4-*amino-3,5-dibromophenyl ethyl ether*, glistening needles, m. 79° . The constitution was established by diazotizing and reducing, 3,5-Br₂C₆H₂OEt, b. $266-7^{\circ}$, being formed. 33 g. *o*-MeC₆H₄NH₂ in 60 cc. AcOH, treated with 180 cc. Br soln., gave 80 g. 2,4,6-MeBr₂C₆H₂NH₂, m. 45° . 2 g. *o*-H₂NC₆H₄CHO, treated with 22 cc. Br soln., gives 4.5 g. 2-*amino-3,5-dibromobenzaldehyde*, m. 110° , probably identical with the product of Bamberger and Demuth (*Ber.*, 34, 1338 (1901)) and of Muller (*C. A.* 4, 205). The constitution was established by diazotizing and reducing, thus forming 3,5-Br₂C₆H₂CHO, m. 90° , and oxidation of this to 3,5-Br₂C₆H₂CO₂H. 2 g. *o*-H₂NC₆H₄Ac and 19 cc. Br soln. gave 4 g. *methyl 2-amino-3,5-*

di-bromophenyl ketone, golden yellow rods, m. 130° . This yields $3,5\text{-Br}_2\text{C}_6\text{H}_3\text{CHO}$ upon diazotizing and reducing. $o\text{-H}_2\text{NC}_6\text{H}_4\text{OMe}$ gives 14.5 g. of the *2-amino-3,5-di-bromophenyl methyl ether hydrobromide*. The free base is an oil. *Hydrochloride*, needles. *Acetate*, prisms, m. 145° . This gives $3,5\text{-Br}_2\text{C}_6\text{H}_3\text{OMe}$ when diazotized and reduced. Diazotized according to Witt, a compound, needles, m. 86° , is obtained. It contains N. 5 g. PhNH_2 in 10 cc. AcOH , treated with 100 cc. Br soln., gave 17.5 g. $\text{Br}_2\text{C}_6\text{H}_3\text{NH}_2$. $m\text{-MeC}_6\text{H}_4\text{NH}_2$ gave a quant. yield of $3,2,4,6\text{-MeBr}_2\text{C}_6\text{H}_2\text{NH}_2$. 3.3 g. $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ gave 8 g. $3,2,4,6\text{-O}_2\text{NBr}_2\text{C}_6\text{H}_2\text{NH}_2$. 5 g. $m\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$ gave 10 g. $3,2,4,6\text{-H}_2\text{NBr}_2\text{C}_6\text{H}_3\text{CHO}$, m. 147° , which, when diazotized and reduced, gave $\text{Br}_2\text{C}_6\text{H}_3\text{CHO}$. *Oxime*, $\text{C}_7\text{H}_4\text{ONBr}_2$, needles, m. 175° . 1.5 g. $m\text{-H}_2\text{NC}_6\text{H}_4\text{Ac}$ in 40 cc. AcOH , treated with 22 cc. Br soln., gave 4 g. *methyl 3-amino-2,4,6-tribromophenyl ketone*, long prisms, m. 121° . *Hydrazone*, needles, m. 120° . Diazotized and reduced, it yields *2,4,6-tribromoacetophenone*, glistening scales, m. 93.5° . Oxidized with alk. KMnO_4 , this yields *tribromophenylglyoxylic acid*, $\text{Br}_3\text{C}_6\text{H}_2\text{COCO}_2\text{H}$, fine needles, m. 174° . When this is boiled with H_2SO_4 it yields $\text{Br}_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$, m. 186° . If 5 g. PhNH_2 in 25 cc. AcOH are treated with 34 cc. Br soln. drop-wise, and the product pptd. with aq. AcONa , 9 g. $p\text{-BrC}_6\text{H}_4\text{NH}_2$ are formed. 5 g. $m\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ in 75 cc. AcOH , treated with 23 cc. Br soln., gave 9 g. $3,4\text{-O}_2\text{NBrC}_6\text{H}_3\text{NH}_2$, m. $125\text{--}6^{\circ}$. In the same way $o\text{-O}_2\text{NC}_6\text{H}_4\text{NH}_2$ gives $2,4\text{-O}_2\text{NBrC}_6\text{H}_3\text{NH}_2$, m. $111\text{--}2^{\circ}$. 5 g. $o\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ gave 9 g. $5,2\text{-Br}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ as the HBr salt, from which the free base is obtained by crystg. from AcONa soln.

C. J. WEST.

Condensation of terephthalaldehyde with methyl 2,3-hydroxynaphthoate. KARL LUGNER. Univ. Vienna. *Monatsh.* 36, 143-67(1915).—In the condensation between $\text{C}_6\text{H}_4(\text{CHO})_2$ and $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{Me}$ only 1 CHO group was reactive, though the 2nd CHO group reacted with MeOH , PhNH_2 , etc. *Methyl 1-[chloro-p-aldehydobenzyl]-2-hydroxy-3-naphthoate (A)*, obtained by condensing bimol. amts. of $\text{C}_6\text{H}_4(\text{CHO})_2$ and $\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{Me}$ in abs. Et_2O with HCl , and allowing to stand several days, yellow needles, m. 180.5° . The yield is small. *Concd. H}_2\text{SO}_4* gives an intense brick-red color, changing to emerald-green upon adding *concd. HNO}_3*. *AcOH* containing 10% H_2SO_4 gives a red color. SnCl_4 gives a red color with an orange fluorescence, changing to light yellow upon warming. FeCl_3 gives a green color which increases in intensity upon standing. *Bromo derivative (B)*, by condensing with HBr , yellow, m. $169\text{--}70^{\circ}$. *Concd. H}_2\text{SO}_4* gives a blue-violet color, changing to green with HNO_3 . SnCl_4 gives a rose color, while the substance becomes a dark brown. *Hydroxy derivative (C)*, best prepd. by treating the Br compd. in acetone with the *calcd. amt.* of H_2O , yellow compact prisms, m. 166° . FeCl_3 gives a deep indigo-blue color, changing to dark green upon warming. The Br compd. decomps. about 10 times as fast as the Cl deriv. *Methyl 1-[methoxy-p-dimethoxymethylbenzyl]-2-hydroxy-3-naphthoate*, prepd. by boiling 3 g. (A) and 100 cc. MeOH 4 hrs., long thin, yellow plates or needles, m. 150° . FeCl_3 gives a green color. *Methyl 1-[methoxy-p-aldehydobenzyl]-2-hydroxy-3-naphthoate*, obtained by boiling (A) and PhOH in C_6H_6 with Na , fine needles from acetone, m. 171° . *Concd. H}_2\text{SO}_4* gives an orange-red color, becoming brick-red upon adding HNO_3 . FeCl_3 gives a yellowish green color. *p-Cresoxy derivative*, small light yellow needles, m. 203° . *p-Cymoxy derivative*, yellow rhombic leaflets, or long needles, m. 186° . FeCl_3 gives a green color. NH_3 reacts with (A) but no definite compd. could be isolated. If 2 mols. PhNH_2 and 1 mol. (A) are boiled 1.5 hrs. in C_6H_6 , *methyl 1-[anilino-p-phenylasomethinbenzyl]-2-hydroxy-3-naphthoate* results, short, thin rods, m. 171° . The same product is obtained with 3 mols. PhNH_2 . *Concd. H}_2\text{SO}_4* gives a yellow color, changing to olive-green and then brown upon adding HNO_3 . SnCl_4 gives a yellow-brown color. *1-[Anilino-p-aldehydophenylhydrazonobenzyl] derivative*, prepd. by b. 2.4 g. anil and 0.7 g. PhNHNH_2 in C_6H_6 , m. 202° (decompn.). It is unstable in the air or light.

Warm concd. H_2SO_4 gives a brick-red color, which is changed by HNO_3 into olive-brown and then emerald-green. HClO_4 gives a citron-yellow soln., while the substance is colored olive-green. 1-[Hydroxy-*p*-aldehydophenylhydrazonobenzyl] derivative, from mol. amts. of (C) and PhNHNH_2 , by boiling 10 min. in C_6H_6 , m. 215° . Concd. H_2SO_4 gives a dark violet color, changed to light olive-green by adding HNO_3 . HClO_4 gives a pale green color but colors the compd. violet-black. Methyl 1-[piperidino-*p*-aldehydobenzyl]-2-hydroxy-3-naphthoate, prep'd. by treating 1 mol. (A) with 2 mols. $\text{C}_8\text{H}_{11}\text{N}$ in little CHCl_3 , boiling 0.5 hr. and adding 10 vols. Et_2O and filtering after 0.5 hr., 6-sided leaflets, m. 171° . H_2SO_4 gives a golden yellow soln., which HNO_3 changes to olive-brown. FeCl_3 gives a reddish yellow color, changing very rapidly through lilac and violet to dark blue. 1-[Azobenzeneamino-*p*-azobenzene-*p*-asomethinbenzyl] derivative, $\text{PhN}:\text{NC}_6\text{H}_4\text{N}:\text{CHC}_6\text{H}_4\text{CH}(\text{NHC}_6\text{H}_4\text{N}:\text{NPh})\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{Me}$, from 1 mol. (A) and 3 mols. $\text{PhN}:\text{NC}_6\text{H}_4\text{NH}_2$, long orange needles, m. 219° . Hydrochloride, violet-red. Concd. H_2SO_4 gives a brick-red, HClO_4 a deep reddish yellow, SnCl_4 a deep orange-red, FeCl_3 a red-yellow color. 1-[Hydroxy-*p*-aldehydthiosemicarbazonebenzyl] derivative, $\text{H}_2\text{NCSNHN}:\text{CHC}_6\text{H}_4\text{CH}(\text{OH})\text{C}_{10}\text{H}_6(\text{OH})\text{CO}_2\text{Me}$, long, thin, microscopic, yellow needles, m. 210° . Concd. H_2SO_4 gives a brick-red soln. which HNO_3 changes through blue and violet into green, finally becoming brown. HClO_4 gives a brick-red color, which upon warming becomes olive-green and then reddish brown. FeCl_3 gives a green color gradually becoming darker. Silver salt, white amorphous flakes which soon form a dark brown powder. It is rather stable in the light and gradually carbonizes above 150° . C. J. WEST.

Chlorination of cyclic ketones with antimony pentachloride. ALFRED ECKERT AND KARL STEINER. Univ. Prag. *Monatsh.* 36, 175-89 (1915).—In the reaction of SbCl_5 upon cyclic ketones, perchloro derivs. are first obtained, which then are more or less decomp'd. into halogen acids and hydrocarbons. Ordinarily 1 part substance was heated 6-8 hrs. with 15-20 parts SbCl_5 and a trace of I. After cooling the Sb and SbCl_5 were removed by washing with HCl and with H_2O . 10 g. $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_4$, treated as above, gave 3 g. $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})_2$, sep'd. by extn. with HCl , 5 g. $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})\text{COC}_6\text{Cl}_5$, extd. with dil. Na_2CO_3 , 5 g. C_6Cl_6 , extd. with Et_2O or C_6H_6 , and about 6 g. $\text{Cl}_4\text{C}_6(\text{CO})_2\text{C}_6\text{HCl}_3$, which remains after the residue is extd. with glacial AcOH . Heptachloro-anthraquinone, $\text{Cl}_4\text{C}_6(\text{CO})_2\text{C}_6\text{HCl}_3$, yellowish green needles from PhCl , m. 380° , difficultly sol. in concd. H_2SO_4 . Zn and NaOH or $\text{Na}_2\text{S}_2\text{O}_4$ gives a red dye-bath. Treated with SbCl_5 for 8 hrs., about 0.5 is recovered unchanged while the remainder is found as C_6Cl_6 , $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})_2$ and $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})\text{COC}_6\text{Cl}_5$. Perchlorobenzoylbenzoic acid, $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})\text{COC}_6\text{Cl}_5$, diamond-like 6-sided tables, m. 266° (decompn.). Chloride, m. 180° , does not react with cold H_2O or alc. Methyl ester, by boiling the chloride with a large excess of MeOH several hrs., m. 213° . 1 g. acid heated 0.5 hr. with 10 cc. concd. H_2SO_4 at $200-250^\circ$, gave $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})_2$ and C_6HCl_3 . Heated with SbCl_5 the acid gives $\text{Cl}_4\text{C}_6(\text{CO}_2\text{H})_2$ and C_6Cl_6 . $(\text{C}_6\text{H}_5)_2\text{CO}$ and SbCl_5 give $(\text{C}_6\text{Cl}_5)_2$, m. 340° , and pentachloro-*o*-phenyltetrachlorobenzoic acid, $\text{Cl}_5\text{C}_6(\text{CO}_2\text{H})\text{CCl}_5$, extd. as the Na salt with Na_2CO_3 and purified by pptn. of the acid from AcOH by H_2O , and finally subliming *in vacuo*, leaflets, m. 264° . From MeOH it crystals with 1 mol. MeOH . The same acid is obtained by treating 1 part $(\text{C}_6\text{H}_4\text{CO})_2$ with 15 parts SbCl_5 , heating 3 hrs., then adding 10 parts SbCl_5 and heating 5 hrs. Xanthone gave a small amt. of $\text{C}_6\text{Cl}_6\text{CO}_2\text{H}$, m. 199° , and C_6Cl_6 , besides octochloroxanthone, yellowish needles, m. 324° , sublimes undecomp'd. *in vacuo*. Acridone gave as the only cryst. reaction product octochloroacridone, long slightly yellow needles, m. 340° . PhCl gives a red-violet soln., with a brownish red fluorescence. Warm H_2SO_4 gives a green soln. with a yellowish green fluorescence. If the compd. is heated longer with SbCl_5 , there results a small amt of C_6Cl_6 and $\text{Cl}_4\text{C}_6\text{CO}_2\text{H}$. Methylacridone gave the same reaction products as acridone. Only small amts. of the acid were obtained. C. J. WEST.

Action of organo-magnesium compounds upon methyl *o*- and *p*-cresotinate. H. BERLITZER. Univ. Vienna. *Monatsh.* 36, 191-209(1915).—A soln. of 3 mols. of EtBr and Mg, after warming 1 hr., is treated with 1 mol. 2,3-(HO)MeC₆H₃CO₂Me in Et₂O, the mixt. warmed 4-5 hrs. and decompd. with dil. AcOH with cooling, giving 72% of 3-methyl-2-hydroxy-1-diethylmethanolbenzene, (HO)MeC₆H₃C(Et)₂OH, flat leaflets from dil. alc. Boiled with Ac₂O and 1.5 times its wt. of AcONa for 10 hrs., a 75% yield of 3-methyl-2-acetoxy-1-[1-ethyl-1-propene]benzene, (AcO)MeC₆H₃CET:CHMe, is formed, *b*₁₁ 124-7°. Sapond. by boiling 3 hrs. with 25% alc. KOH it gives the 2-hydroxy derivative, *b*₁₃ 108-12°. This adds Br without evolution of HBr but upon concg. the CS₂ soln. HBr is given off and no cryst. compd. was isolated. 3-Methyl-2-hydroxy-1-dipropylmethanolbenzene, long wide prisms, *m.* 157°. Yield, 80%. 3-Methyl-2-acetoxy-1-[1-propyl-1-butene]benzene, *b*₁₁ 138-42°. Sapond. this gives the 2-hydroxy derivative, (HO)MeC₆H₃CPr:CHET, *b*₁₁ 124-7°. 3-Methyl-2-hydroxy-1-dibenzylmethanolbenzene, purified by distn. of the (PhCH₂)₂ with steam and crystn. of the residue from C₆H₁₁OH, thin prisms, *m.* 121-2°. In attempting to prep. an unsatd. deriv., the compd. was boiled 6 hrs. with Ac₂O and AcONa, treated with AcCl in C₆H₅N, with Ac₂O and H₂SO₄ and boiled 5 hrs. with 40% H₂SO₄, but no definite compd. could be isolated. 3-Methyl-2-hydroxy-1-[diphenylmethanol]benzene, compact monoclinic prisms, *m.* 120-1°. Conc'd. H₂SO₄ gives a dark red soln. The same compd. was obtained by using 5 mols. PhMgBr. 3-Methyl-2-hydroxy-1-[di- α -naphthylmethanol]benzene, *m.* 214°. The yield is 10%, much C₁₀H₈ being isolated. The soln. is unstable in the air. 5-Methyl-2-hydroxy-1-diethylmethanolbenzene, from 4 mols. EtMgBr and 1 mol. 5,2-Me(OH)C₆H₃CO₂Et, flat leaflets from dil. alc., *m.* 81-2°. 5-Methyl-2-acetoxy-1-[1-ethyl-1-propene]benzene, *b*₁₂ 138-9°. 2-Hydroxy derivative, *b*₁₀ 116-9°. 5-Methyl-2-hydroxy-1-dipropylmethanolbenzene, wide needles, *m.* 84-5°. Yield, 80%. 5-Methyl-2-acetoxy-1-[1-propyl-1-butene]benzene, *b*₁₂ 150-2°. 2-Hydroxy derivative, *b*₁₁ 136-8°. 5-Methyl-2-hydroxy-1-dibenzylmethanolbenzene, compact crystals, *m.* 111-2°. 5-Methyl-2-hydroxy-1-diphenylmethanolbenzene, hexagonal crystals, *m.* 166-7°; conc'd. H₂SO₄ gives an orange color. Heated above its *m. p.* it decomp., giving 7-methyl-*o*-phenylxanthene, microscopic needles, *m.* 145°. 5-Methyl-2-hydroxy-1-di- α -naphthylmethanolbenzene, microscopic crystals, *m.* 184°.

C. J. WEST.

Asymmetric synthesis of mandelic acid and production of ethyl benzylidenetartarate and benzylidenetartaric acid. EMIL ERLÉNMEYER. Dahlen. *Biochem. Z.* 68, 351-67(1915); cf. *C. A.* 8, 3431.—Even though it has not been possible to isolate a pure asym. optically active BzH from the reaction product of BzH and (HOCHCO₂H)₂ (which is practically impossible because of the ease with which it is racemized), yet the fact that optically active PhCH(OH)CO₂H may be obtained in a yield of 0.05% indicates its existence. Neither of the 2 principal reaction products mentioned below, when treated with KCN, gives an optically active PhCH(OH)CO₂H. Diethyl benzylidenetartarate, PhCH

$$\begin{array}{c} \text{OCHCO}_2\text{Et} \\ \diagup \quad | \quad \diagdown \\ \text{PhCH} \quad \text{OCHCO}_2\text{Et} \end{array}$$
 , freed from BzH by first distg. *in vacuo*, and then removing the traces with steam and from BzOH by shaking with NaHCO₃, large compact crystals from petrol. ether, *m.* 48-9°, [α]_D -40°. 100 g. BzH and 150 g. C₆H₆O₆ gave 2.5 g.; using alc. HCl as the condensing agent, 5 g. ester were obtained from 50 g. C₆H₆O₆. The NaHCO₃ washings gave benzylidenetartaric acid, also obtained by sapon. of the ester, fine needles from C₆H₆, *m.* 124°, [α]_D -31°. It is very unstable, so that the *m. p.* is 80° after a few hrs. Boiled with H₂O it is decompd. into BzH and C₆H₆O₆. The difficultly sol. amorphous silver salt is more stable.

C. J. WEST.

Rate of saponification of derivatives of ethyl benzoate. HAMILTON MCCOMBIE AND HAROLD A. SCARBOROUGH. Univ. Birmingham. *J. Chem. Soc.* 107, 156-62

(1915); *Proc.* **30**, 294-5.—M. and S. have studied the velocity of sapon. at 30° of the following Et esters: BzOEt and the 3 isomeric $\text{MeC}_6\text{H}_4\text{CO}_2\text{Et}$, $\text{ClC}_6\text{H}_4\text{CO}_2\text{Et}$, $\text{BrC}_6\text{H}_4\text{CO}_2\text{Et}$, and $\text{IC}_6\text{H}_4\text{CO}_2\text{Et}$. Their methods have been previously described (cf. *C. A.* **8**, 3024). Phenolph. was the indicator used. Halogen substituents show a marked increase in the rate of sapon. in comparison with BzOEt, the influence of the halogen being greatest in the *m*-, least in the *o*-position. The influence of $\text{Cl} > \text{Br} > \text{I}$ (except when the halogens occupy the *p*-positions, when the order is reversed; cf. Meyer and Kellas, *Z. physik. Chem.* **24**, 221). When graphs are drawn, taking the at. wt. of the halogen radicals (in any 1 position) as abscissas and the corresponding sapon. velocities (*k*) as ordinates, *straight lines* are obtained in all 3 cases (*o*, *m* and *p*), the value of *k* for the Br-substituted ester being (in each case) a mean between the values of *k* for the corresponding Cl and I isomers. The introduction of the Me group causes a marked retardation in the rate of sapon. Retardation is also produced by NH_2 , MeO and HO groups, while the NO_2 group causes a decided acceleration. M. and S. find that for BzOEt and KOH at 14.4°, in H_2O , $k = 0.83$, whereas in abs. EtOH, $k = 0.00543$, but offer no explanation.

LOUIS E. WISE.

Hydroaromatic ketones. III. 1-Isopropylcyclohexan-3-one. ARTHUR W. CROSSLAY AND WALTER R. PRATT. King's College, London. *J. Chem. Soc.* **107**, 171-6 (1915).—The greater part of this work has been previously outlined (cf. *C. A.* **9**, 613). *iso*-Pr.CH.CH₃.CO.CH:C(OH).CH₃ (A) (70% yield), was prepd. by the following

method: 23 g. Na in 275 cc. abs. EtOH were heated on a steam bath with 170 g. $\text{CH}_2(\text{CO}_2\text{Et})_2$ and 112 g. of $\text{Me}_2\text{CHCH}:\text{CHAc}$ for 2 hrs., the mixt. evapd., dild. to 2 l. and treated with 900 g. of 10% aq. KOH, boiled for 0.25 hr., acidified with aq. H_2SO_4 and again boiled to expel CO_2 . (A) sepd. as an oil which crystd. The *anilide* of (A), needles, m. 175°. The following derivs. (whose mother substances have been previously described) were also prepd.: 5-chloro-1-isopropyl- Δ^4 -cyclohexene-3-one *semi-carbazone*, plates, m. 193° (decompn.); 1-isopropylcyclohexanyl 3-benzoate, b₃₅ 210°.

LOUIS E. WISE.

Synthesis of *p*-thiol- β -phenylethylamine. HAROLD KING. *J. Chem. Soc.* **107**, 222-30 (1915).—The synthesis of *p*-thiol- β -phenyl ethylamine (A), $\text{SHC}_6\text{H}_4(\text{CH}_2)_2\text{NH}_2$, hexagonal leaflets, m. 216-7° (from H_2O), may be outlined as follows: *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Sn} + \text{HCl}$ in EtOH

$\text{H}_4(\text{CH}_2)_2\text{NHBz} \xrightarrow{\text{H}_2\text{NC}_6\text{H}_4(\text{CH}_2)_2\text{NHBz} \text{ (B), m. 133.5-4.5° (cf. Barger and Walpole, C. A. 4, 1018)}}$ $\xrightarrow{\text{diazotization} + \text{K xanthate}}$

$\text{EtSOCSN}_2\text{C}_6\text{H}_4(\text{CH}_2)_2\text{NHBz}$
(not isolated) $\xrightarrow{\text{benzo-}p\text{-xanthyl-}\beta\text{-phenylethyl amide, } p\text{-EtSOCS.C}_6\text{H}_4(\text{CH}_2)_2\text{NHBz}}$
(not purified) $\xrightarrow{\text{hydrolysis in EtOH with aq. KOH}}$

$\xrightarrow{\text{benzo-}p\text{-thiol-}\beta\text{-phenylethylamide, micro-} + \text{alk K}_3\text{Fe(CN)}_6}$

needles, very sensitive to oxidation $\xrightarrow{\text{dibenzodi-}\beta\text{-phenylethylamide}}$
p-disulfide, $[\text{SC}_6\text{H}_4(\text{CH}_2)_2\text{NHBz}]_2$, minute needles (from AcOH), m. 199-201°, hydrolysis at 150° with 20% aq. HCl

$\xrightarrow{\text{di-}\beta\text{-phenylethylamine } p\text{-disulfide dihydrochloride}}$
(C), $[\text{SC}_6\text{H}_4(\text{CH}_2)_2\text{NH}_2\text{HCl}]_2$, microscopic hexagons (from 5% aq. HCl), m. 339.5-40.5°

$\xrightarrow{\text{Sn} + \text{HCl in EtOH}}$ $\xrightarrow{\text{hydrochloride of (A), filmy leaflets (from abs. EtOH), neutralization} + \text{NaOH}}$
m. 31.5-3.0° $\xrightarrow{\text{(A). The picrate of (A), orange needles, m. 156.5-7.5° (decompn.).}}$

The hydrochloride of (B), hexagons, decomp. 283-5°; sulfate, leaflets, m. 278-9° (decompn.). Acetyl derivative of (B), rectangular leaflets, m. 209.5-10.5°. The sulfate corresponding to (C) forms silky leaflets; the corresponding picrate, *syphnate* and the free base, $[\text{SC}_6\text{H}_4(\text{CH}_2)_2\text{NH}_2]_2$ (D), are oils. (A) when heated with H_2SO_4 gives a purple color, does not respond to Millon's test, and gives a primrose-yel-

low ppt. with $(\text{AcO})_2\text{Pb}$. (A) has about $1/4$ the pressor activity while (D) approx. $1/30$ the activity of $p\text{-HOC}_6\text{H}_4(\text{CH}_2)_3\text{NH}_2$, when intravenously injected into cats.

LOUIS E. WISE.

Nitroguaiacols. DAVID CARDWELL AND ROBERT ROBINSON. Univ. Manchester and Sidney. *J. Chem. Soc.* 107, 255-9(1915).— $o\text{-(MeO)}_2\text{C}_6\text{H}_4$ (A) was readily nitrated, with the formation of $1,2,4\text{-(MeO)}_3(\text{O}_2\text{N})\text{C}_6\text{H}_3$ (B), (99% yield), by gradually adding 25 g. of (A) to a cooled mixt. of 20 cc. HNO_3 (d. 1.42) and 20 cc. H_2O . When 5 g. (B) are heated on a steam bath with 15 cc. satd. HBr , 5-nitroguaiacol (C), $1,2,5\text{-(HO-(MeO)(O}_2\text{N))C}_6\text{H}_3$, pale yellow needles, m. $104\text{--}5^\circ$, is obtained; *acetate*, m. 101° . (C) is also obtained by the semi-methylation of nitrocatechol, and by the nitration of $o\text{-AcO(MeO)C}_6\text{H}_4$. When 5 g. nitroveratrole were boiled under reflux with 10 g. KOH , 50 cc. MeOH and 20 g. H_2O , for 12 hrs., 4-nitroguaiacol (D), pale yellow needles, m. $101\text{--}2^\circ$, were formed. (D) has been previously prepd. by Rupe (*Ber.* 30, 2446) and (C) has been synthesized by Cousin (*J. pharm. chim.* 9, 276), but the 2 products were erroneously believed to be identical. Mixts. of (C) and (D) m. $72\text{--}6^\circ$. When 6-nitrohomoveratrole was heated with glacial AcOH and satd. aq. HBr , 6-nitro 4-hydroxy-m-tolyl methyl ether (E), $1,3,4,6\text{-Me(MeO)(HO)(O}_2\text{N)C}_6\text{H}_3$, yellow prisms, m. $138\text{--}40^\circ$, was obtained. Its *potassium salt* formed yellow needles; *acetate*, feathery needles, m. $138\text{--}9^\circ$. A by-product in the (E) synthesis was identical with Cousin's non-volatile nitrohomocatechol (cf. *Bull. soc. chim.* 9, 53, 157).

LOUIS E. WISE.

Silicon compounds. VIII. Preparation and constitution of silico-oxalic acids, and the action of methyl and ethyl alcohols on trisilicon octachloride. GEOFFREY MARTIN. London. *J. Chem. Soc.* 107, 319-28(1915).—Neither Friedel and Ladenburg (*Ann.* 203, 250(1880)) nor Gattermann and Weinlig (*Ber.* 27, 1943(1894)) were able to prepare pure silico-oxalic acid, $(\text{SiO}_2\text{H})_x$, by the decompn. of disilicon hexahalides. An acid of 99-100% purity was obtained by hydrolysis of $\text{Si}_2(\text{OEt})_6$ with cold H_2O for 48 hrs. It is a white, amorphous, hygroscopic solid, decomp. explosively when scratched, rubbed, or suddenly heated, evolves the theoretical amt. of H when treated with 50% aq. KOH . If warmed, or prepd. by means of hot H_2O , or if unduly handled, it evolves too little H. An attempt was made to prep. $\text{Si}_2(\text{OEt})_6$ in order to effect a similar synthesis of mesosilico-oxalic acid, $\text{HO}_2\text{Si.Si(OH)}_2\text{SiO}_2\text{H}$ (A). However, the action of EtOH on Si_2Cl_4 resulted in the formation of Si(OEt)_4 , and an inseparable mixt. of very labile products which could not be isolated. Similar results were obtained with MeOH , except that the decompn. of the Si.Si.Si chain was not quite so marked, as was shown by the greater evolution of H when the products of the reaction were treated with alkali (*C. A.* 6, 2923; 8, 345). (A), prepared by exposing Si_2Cl_4 to atm. moisture, is much more explosive than $(\text{SiO}_2\text{H})_x$, as would be expected from the great instability of the Si_3 chain observed above.

M. HEIDELBERGER.

Condensation of acetone and benzaldehyde with glycerol. Preparation of glycerol α -methyl ether. JAMES C. IRVINE, JAMES L. A. MACDONALD AND CHARLES W. SOUTAR. Univ. St. Andrews. *J. Chem. Soc.* 107, 337-51(1915).—An attempt to derive information as to the mechanism of the formation of condensation products between polyhydric alcs. and acetone or BzH . Since only 1 Me group can be introduced into isopropylideneglycerol (A), formulas based on a condensation with acetone in the enol form may be discarded and only (I) and (II) need be considered. To obtain (A)

free from unchanged glycerol (*B*) it is best prepd. by the following modification of Fischer's method: 100 g. freshly distd. (*B*) were shaken until dissolved with 650 cc. dry acetone containing 1% HCl. After 24 hrs. the soln. was neutralized with PbCO_3 , or with Ag_2CO_3 , warmed with bone-black, and shaken with a large excess of CaCl_2 . The soln. was decanted from the syrupy residue, evapd., and fractionated *in vacuo*. Yield, 88.7 g., $b_{11} 86.5^\circ$, $d_4^{18} 1.0727$, $n_D 1.4383$. To 80 g. (*A*) in 280 g. MeI were gradually added 200 g. Ag_2O . After the first vigorous reaction had ceased, the mixt. was boiled 6 hrs. and then extd. with Et_2O . This yielded 61 g. *isopropylideneglycerol methyl ether*, mobile liquid, $b_{11} 57^\circ$, $b_D 75^\circ$, $d_4^{16} 0.9900$, $n_D 1.4177$, readily hydrolyzed by traces of acids. When boiled 20 min. in 75% alc. containing 0.5% HCl it gives *glycerol α -methyl ether* (*C*), $b_{11} 110^\circ$, $d_4^{17} 1.1197$, $n_D 1.4463$, sol. in H_2O . *o*- $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ and (*C*) give a mixt. of mono- and di-acid phthalates which could not be resolved, owing to the difficulty in sepg. the alkaloidal salts. Dry HCl was slowly bubbled into *l*-menthone until the vol. corresponding with a 1% soln. had been absorbed. The soln. was then dild. with an equal vol. of Et_2O and shaken 48 hrs. with (*C*). Neutralization of the product with Ag_2CO_3 could be completed only after adding a small amt. of H_2O . The resulting *l*-menthylideneglycerol methyl ether, $b_{11} 135-6^\circ$, did not cryst., and could not be resolved by partial hydrolysis. PBr_3 and (*C*) in CHCl_3 , finally boiled 45 min., allowed to stand overnight, and washed with aq. Na_2CO_3 and H_2O , gave chiefly non-volatile sirup of the formula $(\text{HO})_2\text{POCH}_2\text{CHBrCH}_2\text{OMe}$ or $\text{BrCH}_2\text{CH}[\text{OP}(\text{OH})_2]\text{CH}_2\text{OMe}$, and a small amt. of a mixt. of the bromohydrin and $\text{BrCH}_2\text{CHBrCH}_2\text{OMe}$ (*D*). After 2 treatments with PBr_3 the latter was obtained pure. PBr_3 and (*C*) yielded chiefly P-containing, non-volatile material and a little (*D*) contaminated with a small amt. of a substance containing more Br. In an attempt to produce a mixed ether with EtI and Ag_2O , oxidation also occurred and *ethyl β -methoxy- α -ethoxypropionate* was formed, mobile liquid, $b_{11} 57-8^\circ$. (*C*) was synthesized as follows: $\text{MeOCH}_2\text{CH}:\text{CH}_2$ was prepared by methylating $\text{C}_4\text{H}_9\text{OH}$ by the Ag_2O reaction and from $\text{C}_4\text{H}_9\text{I}$ and NaOMe ; on bromination it yielded *dibromo- α -methoxypropane* (*D*), which was fractionated until its n was const.; it $b_{11} 81^\circ$, $d_4^{20} 1.8329$, $n_D 1.5143$; heated at 160° with aq. alc. AgOAc for 30 hrs. it gives (*C*) after complete hydrolysis with 5% aq. $\text{Ba}(\text{OH})_2$ of the partially hydrolyzed acetate first formed. A product identical with (*D*) was prepd. from (*C*) by heating this at 180° for 2 hrs. with $(\text{CO}_2\text{H})_2$ and a trace of $(\text{NH}_4)_2\text{SO}_4$, then at 230° for 8 hrs., with occasional addition of more $(\text{CO}_2\text{H})_2$, and brominating the resulting distillate of MeOC_4H_9 . Benzylideneglycerol (Gerhardt, *C. A.* 7, 868), when methylated with Ag_2O and MeI free from acid and I, gave *benzylideneglycerol methyl ether* (*E*), $b_{11} 121^\circ$, $d_4^{15} 1.1263$, $n_D 1.5170$, is hydrolyzed even by the traces of acid in lab. air. Hydrolysis yields (*C*). The (*C*) prepd. from (*A*) gives (*E*) when condensed with BzH , and the (*C*) prepd. from (*E*) yields (*A*) when condensed with acetone. By the above methods it is therefore demonstrated that (*A*) and the corresponding benzylidene deriv. have the constitution (II).

M. HEIDELBERGER.

Removal of oxygen from triethylphosphine oxide. JOHN N. COLLIE AND FRANK REYNOLDS. London. *J. Chem. Soc.* 107, 367-9.—It is well known that Et_3PO (*A*) is unchanged by ordinary reducing agents and may even be distd. over Na. It may also be distd. over Zn and Mg. 5.66 g. (*A*) and 8 g. PCl_3 reacted readily. After distg. off the POCl_3 the resulting *triethylphosphine dichloride* crystd. With H_2O it gives back (*A*); reduced by boiling in alc. with Na-Hg, it gives Et_3P . The dichloride could not be prepd. pure; on distn. it decompd., giving EtCl and other inflammable gases, C, yellow P, and a mixt. containing traces of Et_3PCl_2 and Et_2PHCl . This was again distilled, but again decompd. to a great extent. In another expt., by adding the distillate from the dichloride to dil. HNO_3 , evapg. to dryness, and converting into the Ag salt of $\text{Et}_3\text{PO}_2\text{H}$ with Ag_2O and b. H_2O , it was shown that the chief product of the decompn.

is Et_3PCl , according to the equation $\text{Et}_3\text{PCl}_2 = \text{Et}_2\text{PCl} + \text{EtCl}$. This behavior is similar to that of analogous compds. of As and Bi.

M. HEIDELBERGER.

Some benzopyranol derivatives. JOHN N. COLLIE AND GERALD N. WHITE. London. *J. Chem. Soc.* **107**, 369-76.—A paper dealing with an additional simple condensation of $-\text{CH}_2\text{CO}-$ derivs. (cf. C., C. A. **2**, 798). Condensation of orcinol and CH_3Ac , either undil. or in soln., is readily effected by means of concd. HCl, dry HCl, concd. HBr, or H_2SO_4 , giving salts of 2 bases, $\text{C}_{12}\text{H}_{12}\text{O}_2$ (I) and (II). Since each

of the starting products may be obtained from HOAc, the reaction may be summarized as follows: $7\text{H}(\text{CH}_2\text{CO})\text{OH} = \text{C}_{12}\text{H}_{12}\text{O}_2 + 2\text{CO}_2 + 8\text{H}_2\text{O}$. The orange hydrochloride of (II), 5-hydroxy-2,7-dimethyl-4-methylene- γ -benzopyranol, is best sep'd. from the lemon-yellow hydrochloride of (I), 7-hydroxy-2,5-dimethyl-4-methylene- γ -benzopyranol, by means of its lower solubility in concd. HCl. Both cryst. with 1 mol. H_2O , which is driven off at 100° ; both decomp. between 200° and 235° . Below are given data for the derivs. of (I) and (II), resp.: *Free bases*, orange, sol. in NaOH with a pale yellow color; violet, almost colorless in NaOH, gives a pale brown soln. in alc., changing to violet when hot. *Hydrobromides*: Greenish yellow and orange, sep'd. in the same way as the HCl salts. *Chloroplatinates*: Yellow, evolve Cl when boiled a few moments in soln. and give chloroplatinites, crystals. *Perchlorates*: Greenish yellow, readily sol. in cold aq. HClO_4 , the soln. decomp. when warmed; orange crystals with 1 H_2O , difficultly sol. in aq. HClO_4 ; both deflagrate when heated. HgCl_2 gives a mixt. of mercurio- and mercurichlorides of which the latter are sol. in cold $\text{C}_6\text{H}_5\text{N}$. *Mercurichlorides*: Deep orange, gives a crimson soln. in $\text{C}_6\text{H}_5\text{N}$; purple, gives a violet color in $\text{C}_6\text{H}_5\text{N}$; both are reduced to the mercuriochlorides in cold alc. *Mercuriochlorides*: Orange and purple, insol. in $\text{C}_6\text{H}_5\text{N}$. Reduction of the HCl salts with Zn in boiling HCl gave colorless, amorphous dihydro derivatives (A); feebly basic; that from (I) gave a similar tetrahydro derivative with Al-Hg, has no basic properties. Both (A), nitrated in AcOH, give needles, decomp. at 100° ; formulas: $\text{C}_{12}\text{H}_{12}\text{O}_4\text{N}$ and $\text{C}_{12}\text{H}_{12}\text{O}_6\text{N}_2$. Reagents reacting with keto groups gave indefinite results, it thus appearing that, at least in basic solns., the compds. (I) and (II) do not react in the quinoidal form. The Ac derivs. (not described) do not have basic properties, strange to say. With concd. HCl, phloroglucinol and CH_3Ac (excess) gave first a yellow hydrochloride, $\text{C}_{11}\text{H}_{10}\text{O}_4\text{HCl}$, and later, an orange salt, $\text{C}_{17}\text{H}_{14}\text{O}_6\text{HCl}$, the latter a condensation product of phloroglucide.

M. HEIDELBERGER.

Double halides of quinine and urea. II. P. G. GOLUBEV. *J. Russ. Phys. Chem. Soc.* **47**, 14-7(1915); (cf. C. A. **8**, 2549).—A double hydriodide of quinine and urea, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2\text{HI} \cdot \text{CH}_4\text{ON}_2\text{HI} \cdot 5\text{H}_2\text{O}$ (a), was made by mixing hot solns. of quinine bisulfate and urea. If the diln. is not too great (8-10%), the cooled soln. deposits within 24 hrs. a mass of long, transparent, bright, yellow crystals (yield, 80-5%), m. $62-4^\circ$, sol. in 18 parts of cold H_2O , loses all of its H_2O of hydration in the air. At its 1st recrystn. from 8-10 parts of hot H_2O it leaves a small amt. of a red, amorphous powder (not examd.). (a) may also be made from urea and com. quinine dihydriodide, but then it contains more of the red powder. Heated to 100° , (a) decomp. into $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 \cdot 2\text{HI} + \text{CO}_2 + 2\text{NH}_3$. A small amt. of an insol. red powder is also produced in this

decompn. On evapg. a soln. of (a) in 20-5 parts of H_2O by exposure to the air at ordinary temp., partial decompn. takes place with formation of *quinine sesquihydriodide*, $C_{20}H_{24}O_2N_2 \cdot 1.5H_2I$ (b), white, silky, filiform crystals, m. $42-5^\circ$, sol. in 22 parts of cold H_2O . Being considerably lighter than (a), (b) floats on the surface when the 2 are shaken with H_2O , and may thus be sepd. from (a). (b) may be changed to (a) by dissolving it in H_2O and adding a little urea and 2-3 drops of HI soln. The white com. *Chininum hydriodicum* was found to be impure $C_{20}H_{24}O_2N_2 \cdot HI \cdot H_2O$. H. M. GORDIN.

Action of anhydrous aluminium chloride and trioxymethylene on cyclohexane. A. M. NASTYUKOV AND N. V. GURIN. *J. Russ. Phys. Chem. Soc.* 47, 46-52(1915).—Neither C_6H_{12} nor C_6H_{14} interact with $AlCl_3$ and $(CH_2O)_3$. Naphthenes, C_7H_{16} , C_8H_{18} and cyclohexane (a) react under these conditions, forming both dehydrogenation and condensation products, together with sol. formolite. From the reaction product of (a) no definite compd. could be isolated, save a small amt. of C_6Me_6 . H. M. G.

Relation between absorption and structure. V. A. ISMAIL'SKII. *J. Russ. Phys. Chem. Soc.* 47, 63-100(1915).—A critical exam. of the proposed hypothesis on the relation between color and structure. Both the carbonium hypothesis of Baeyer and Villiger (*Ber.* 38, 571) and the quinoid or quinone-carbonium hypothesis of Gomberg (*Ann.* 376, 183) and other investigators are considered inadequate to account for the various phenomena of halochromy. The existence of colored substances in which the carrier of color is in some cases an org. group acting as anion (anhalochromy), while in other cases it acts as cation (cathalochromy), and the possibility of converting the same skeleton of C atoms from the position of cation (chromonium state) to that of anion (chromaci state) speak against the carbonium hypothesis which ascribes color to the basic properties of individual C atoms. Against the quinoid hypothesis speaks the fact that the absorption of light changes continuously when the constitutional factors of the colored substance are changed, it being impossible to tell where the benzoid form ends and the quinoid begins. The most promising hypothesis is that of Kaufmann (*Valenzlehre*, 480) and Gebhard (*J. prakt. Chem.* 84, 561) which ascribes color to a particular condition of the whole mol. resulting from a "shattering," of the valences of a central C atom which becomes the center of color. This hypothesis, in connection with the electronic principle of competition, will be elaborated in another paper. H. M. GORDIN.

Oxonium compounds. A. FAVORSKII AND É. VENUS. *J. Russ. Phys. Chem. Soc.* 47, 133-41(1915).—The *pinacol*, $PhC : CCPh(OH)C(OH)Me_2$ (a), made by the interaction of $BzC(OH)Me_2$ with $PhC : CMgBr$ (yield, about 44%), m. $93-3.5^\circ$. By heating (a) with 20% H_2SO_4 a new oxonium base, *hydroxydimethyldiphenyldihydrofurane* (b), $HOCPh.CH : CPh.O.CMe_2$, m. $101-2^\circ$, was obtained; *hydrochloride*, $C_{18}H_{18}O_2 \cdot$

$2HCl \cdot 2H_2O$ (from (b) in concd. HCl), greenish yellow crystals, m. $61-2^\circ$; *hydrochloride*, $C_{18}H_{18}O_2 \cdot 2HCl$ (from (b) and HCl in Et_2O), yellow crystals, m. $105-7^\circ$; *chloroplatinate*, $(C_{18}H_{18}O_2 \cdot HCl)_2PtCl_4$, orange powder; *chloroaurate*, $C_{18}H_{18}O_2 \cdot HCl \cdot AuCl_3$, yellow powder; *chlorostannate*, $C_{18}H_{18}O_2 \cdot HCl \cdot SnCl_4$, pale green powder; *hydrobromide*, $C_{18}H_{18}O_2 \cdot 2HBr$ (from (b) and HBr in C_6H_6), orange powder, m. 157° in open and 154° in a closed capillary, decomp. when placed in H_2O , first into a yellow hydrated salt, and then into free (b) and acid; *bromostannate*, $C_{18}H_{18}O_2 \cdot HBr \cdot SnBr_4$, yellow powder, m. $180-2^\circ$ in an open and $179-80^\circ$ in a closed capillary; *hydriodide*, $C_{18}H_{18}O_2 \cdot 2HI$, lilac-brown powder, m. $174-6^\circ$ (in a closed capillary); *acid sulfate*, $C_{18}H_{18}O_2 \cdot 2H_2SO_4$ (from (b) and H_2SO_4 in Et_2O), yellow, very hygroscopic powder, m. 163° ; *trichloroacetate*, $C_{18}H_{18}O_2 \cdot 2CCl_3CO_2H$, pale green powder, m. $116-8^\circ$ (decompn.); *acetyl derivative*, $C_{18}H_{17}AcO_2$ (from (b) and Ac_2O), colorless crystals, m. $141-2^\circ$, is not decompd. by alc. KOH and, instead of basic, has acid properties, being sol. in dil. alkalies, giving a soln. from which

it is not extd. by Et_2O . As seen from the comp. of the above salts, the simple salts contain 2 mols. of acid for 1 of (b), hence in them both O atoms are tetravalent. In the double salts, however, there is only 1 mol. of acid for 1 of (b), hence in these 1 O atom only is tetravalent. Since in oxonium bases the basic properties of the O of an OH are very weak, it must be the cyclic O of (b) that is tetravalent in the double salts, the other O being divalent. It is, however, also possible that the double salts are formed with elimination of 1 mol. of acid, giving compds. of the following formula in which both O atoms are tetravalent:

(X = halogen). It is not quite clear why the Ac deriv. with the more basic O intact is devoid of basic properties. H. M. GORDIN.

Stereoisomerism of symmetrical diethyldiphenylethane. A. I. L'YEPIN AND V. N. REIKH. *J. Russ. Phys. Chem. Soc.* 47, 149-60(1915).— EtPhCHOH (a) was made by the action of EtMgBr on BzH ; yield, 77%. Heating with HBr in a sealed tube to 100° converted (a) into EtPhCHBr (b); yield, 78%. By warming (b) to 50° with Na in C_6H_6 a mixt. of PhCH:CHMe , PhBr and *sym. diethyldiphenylethane*, $(\text{CH-PhEt})_2$, was obtained. The latter was produced in 2 stereoisomeric modifications: a liquid of agreeable odor and violet fluorescence (c), b_{767} $297-8^\circ$, d_{20}^{20} 0.9591, n_D^{20} 1.54622; and a solid (d), m. 90° , b_{767} $304-5^\circ$. Oxidation with CrO_3 and KHSO_4 in AcOH converted both (c) and (d) into EtBz . (c) and (d) are partly converted into each other when they are heated with a trace of I in a sealed tube to $250-65^\circ$. Since (c) and (d) contain 2 asym. C atoms in *sym.* arrangement, the hydrocarbon, $\text{C}_{18}\text{H}_{22}$, ought to exist in 4 stereoisomeric modifications. Of these (c) probably is the *dl*-, and (d) the *i*-modification. H. M. GORDIN.

Isomerism of the organo-metallic combinations of pyrrole and their interaction with ethyl carbonate and with ethyl chlorocarbonate. V. V. CHELINTZEV AND S. G. KARMANOV. *J. Russ. Phys. Chem. Soc.* 47, 161-9(1915).—The chief product of the interaction of $\text{C}_4\text{H}_4\text{NMgBr}$ (from Mg , EtBr and $\text{C}_4\text{H}_5\text{N}$) with Et_2CO_3 is *ethyl N-pyrrole-carboxylate* (a), b_{748} $179-80^\circ$, d_{40}^{20} 1.0697, n_{20} 1.4779. Along with (a) are produced small amts. of what seems to be the corresponding α -ester (Oddo, *C. A.* 4, 2460) and of what probably is carbonylpyrrole (Ciamician and Magnani, *Ber.* 18, 419), for which the name carbpyrrole is proposed. The formation of (a) proves that, contrary to Hess (*C. A.* 8, 2706), pyrrol-Mg compds. are, like the K derivs. of pyrrole, capable of giving, according to the conditions, either *N*- or α -pyrrole compds. With the K compds. the tendency is to form *N*-derivs., while the pyrrol-Mg compds. tend to form α -derivs. Most probably in both cases there is a mixt. of the 2 tautomeric forms, CH:CH.CH:CH.NR and CHR.CH:CH.CH:N which, according to the

conditions, change into one another, the ring itself undergoing isomerization. A repetition of Oddo's expts. with ClCO_2Et corroborated his statements, but it was not possible to obtain his $\alpha\text{-C}_4\text{H}_4\text{NCO}_2\text{Et}$ in *cryst.* form. H. M. GORDIN.

Methods of obtaining α,α -dipyrrol ketone. V. V. CHELINTZEV AND D. K. SKVORTZOV. *J. Russ. Phys. Chem. Soc.* 47, 170-6(1915).—Ciamician's method (*Ber.* 18, 1828) for making α,α -dipyrrol ketone (a) gives a very poor yield. The following

2 methods are much better: $\alpha\text{-C}_4\text{H}_4\text{NCO}_2\text{H}$ is changed by means of PCl_5 to the chloride, $\text{C}_4\text{H}_4\text{NHCOCI}$, and the latter is treated with a pyrrol-Mg compd. (b), e. g., that obtained from $\text{C}_4\text{H}_5\text{N}$ and iso-AmMgCl. Yield, over 11%. The 2nd method consists in treating (b) with COCl_2 , 2 mols. of (b) giving 1 mol. of (a). Yield, 28.5%.

H. M. GORDIN.

Action of salts of heavy metals on magnesium-organic compounds. N. V. KONDUIROV AND D. A. FOMIN. *J. Russ. Phys. Chem. Soc.* 47, 190-8(1915).—The interaction of Mg-org. compds., e. g., EtMgI , EtMgBr or PrMgBr , with CuCl , CuBr , CuI , CuCN , CuCNS , CuBr_2 , FeCl_3 , FeCl_2 , CoCl_2 , NiCl_2 , $\text{Fe}(\text{CNS})_2$, $\text{Cr}(\text{CNS})_3$ or $\text{Mo}(\text{CNS})_3$, gives a mixt. of satd. and unsatd. hydrocarbons and Mg salts, while the salt of the heavy metal is reduced, frequently to the metallic state. Thus EtMgBr and CuBr gave C_2H_6 , C_2H_4 , MgBr_2 , and Cu . The aryl-Mg compds. give under these conditions hydrocarbons of double the mol. wt. of the aryl group. Thus PhMgX gives Ph_2 . A repetition of the expts. of Iotzich and Rozhdestvenskii (*J. Russ. Phys. Chem. Soc.* 1908, 1113) with CCl_3CHO and AcPh showed that the reaction is of the same kind as the above, though with CCl_3CHO they failed to isolate the C_6H_6 . The main results of Bennett and Turner (*C. A.* 8, 2361) were corroborated, but K. and F. think CrCl_3 is of value only for making aromatic hydrocarbons, and that CrCl_3 and EtMgBr give not diisamyl, but C_4H_{10} and C_4H_{12} .

H. M. GORDIN.

Action of pyridine on some sulfurated and selenated organic compounds. M. RAFFO AND G. ROSSI. Univ. Bologna. *Gazz. chim. ital.* 45, 28-34(1915).—In a preceding note (*C. A.* 8, 2683) it was shown how $\text{C}_4\text{H}_5\text{N}$ acts catalytically on certain S compds. to give H_2S and more complex compds. PhSH (a), PhCSNH_2 (b), and allylthiourea (c), were similarly treated and the previous results were here, too, verified. In these 3 cases $\text{C}_4\text{H}_5\text{N}$ acts as a catalyzer, giving $(\text{PhS})_2$ with (a), $(\text{C}_4\text{H}_5\text{NCPH})_2\text{S}$ (d) with (b), and an isomer of (c) with (c). Similarly it was thought that $\text{C}_4\text{H}_5\text{N}$ ought to give the same effect with Se derivs. Diphenylselenourea (e) b. with $\text{C}_4\text{H}_5\text{N}$ gave H_2Se , PhNH_2 , carbanilide and $\text{PhN:C}(\text{NHPh})_2$. The PhSH was boiled with a small amt. of $\text{C}_4\text{H}_5\text{N}$ for 10-12 days; the $(\text{PhS})_2$ m. $60-1^\circ$. (b) boiled similarly until H_2S was no longer evolved (many days) gave a yellow cryst. substance (d), $\text{C}_{22}\text{H}_{20}\text{N}_2\text{S}$, m. $202-4^\circ$, identical with the compd. obtained from $\text{PhC}(\text{NH}_2):\text{NH.HCl}$ and the Na salt of PhCSNH_2 (Jamieson, *J. Am. Chem. Soc.* 26, 177), and constitution of which is now detd. by the method of prepn. (c) boiled some days with $\text{C}_4\text{H}_5\text{N}$ evolve H_2S and $\text{C}_4\text{H}_5\text{NCS}$ and gave a cryst. substance, m. 117° , isomeric with (c), $\text{MeCH}_2\text{S.C}(\text{NHPh})_2\text{N.CH}_3$.

(Prager, *Ber.* 22, 2993). When (e) was treated with $\text{C}_4\text{H}_5\text{N}$ and boiled a little H_2Se was evolved. After the $\text{C}_4\text{H}_5\text{N}$ had been removed by distn. the temp. was raised and PhNH_2 passed over (b. $180-2^\circ$). The next fraction, carbanilide, passed over at 260° and crystd. in the receiver, m. 235° . The tarry residue, was treated with Et_2O . The Et_2O was washed with dil. H_2SO_4 and the acid soln. after decolorizing with charcoal was made alk. with NH_3 . The yellowish ppt. was $\text{PhN:C}(\text{NHPh})_2$, m. 143° .

E. J. WITZEMANN.

Introduction of the guanidine nucleus into the molecule of the polypeptides. I. Synthesis of guanidoglycylglycine. ANTONIO CLEMENTI. Univ. Heidelberg. *Gazz. chim. ital.* 45, 56-9(1915).—The chem.-physiol. importance of guanidine (a) arises from the intimate relation between (a) and urea, the presence of the (a) nucleus in creatine and creatinine, the participation of the (a) nucleus in the protein mol. and the formation of urea from the latter by the hydrolyzing action of an imidolytic ferment. C. has worked out a process for prepg. simple guanidopolypeptides which was successfully applied to the prepn. of guanidoglycylglycine (b) or glycocyamylglycine. Glycocyamine is said to be the mother substance of creatine (Jaffe, *Z. physiol. Chem.*

48, 430 (1903)). 1.13 g. glycylglycine (Fischer) in a small amt. of H_2O + 0.36 g. CNNH_2 + a few drops of NH_4OH were kept at room temp. and showed crystals in 4.5 days. In 10 days a mass of white needles of (b) had sepd. (b) is insol. in EtOH and Et_2O , difficultly sol. in H_2O , browns $218-20^\circ$, blackens and decomps. 235° ; the biuret and $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO}$ tests are negative. E. J. WITZEMANN.

Phototropy in solutions. I. B. FORESTI. Univ. Bologna. *Atti accad. Linzei* 23, 270-6 (1914).—Numerous phototropic solids are known but only 1 substance (diphenantholamine) is known which is phototropic in soln. (Schmidt, Lump, *C. A.* 3, 544). Stobbe and Nowak (cf. *C. A.* 8, 114) studied the action of light on PhCH:NNH-Ph (a) in EtOH , but Baly and Tuck (*J. Chem. Soc.* 1906, 988) had shown that this is an oxidizing action and does not take place in the absence of O. F. observed that the same action takes place more quickly in C_6H_6 but not out of contact with the air. 1-2 g. (a) in 100 cc. C_6H_6 in diffuse light becomes rose-colored in 24-48 hrs. and becomes phototropic. Exposed to direct sunlight the rose color becomes lemon-yellow in 15-30 sec., and reverses in 10-15 mins. The change in color may be thus produced and reversed many times. But if the soln. is exposed to the sun too long it loses its capacity for reversing and remains yellow. A lack of O prevents the soln. from becoming phototropic; excess of O causes the soln. to lose its phototropic capacity. If phenylhydrazones (b) altered by contact with the air are used, the phototropy is obtained at once without the presence of O. Such transformed (b) always has an odor of BzH so that the product studied is of unknown constitution. When solns. of (b) are treated with BzH and O the phototropy is accentuated; with much BzH and little O the soln. is colored orange-brown without becoming phototropic. Anhydrous solns. of (a) in C_6H_6 do not become phototropic in contact with the air, but if BzH is added the phototropy appears at once, so that moisture is probably necessary for the hydrolysis by which BzH is produced. The change is probably composed of 2 phases: (1) the BzH is formed; (2) the combined action of O + BzH produces the phototropic substance. Of other solvents tried only PhMe and xylene gave the same effect. Padoa and Minganti (*C. A.* 8,

1368) have shown that $\text{A}_2 \xrightleftharpoons[\text{dark}]{\text{light}} 2\text{A}$ represents the equil. between 2 phototropic forms

and that light has a depolymerizing action. But since in this case light causes an exaltation of the tone of color instead of a diminution and since the phototropic soln. preserves its properties in atms. of inert gases (thus excluding the auto-oxidation and

reduction of Stobbe and Mallison, *C. A.* 7, 2566) it becomes probable that $2\text{A} \xrightleftharpoons[\text{dark}]{\text{light}} \text{A}_2$

represents an action of light. As will be shown below, light acts on phototropic solns. to restrict the region of absorption which Jones and Uhler (*C. A.* 1, 814) have said indicates an increase in mol. complexity. A 40 cm. tube containing 0.5 g. (a) in 100 cc. C_6H_6 was examd. with light having a continuous spectrum and the soln. stable in the dark (rose) absorbed the violet, blue and green, i. e., the visible spectrum from $550\mu\mu$ on. After having been illuminated, absorption began at $510\mu\mu$, i. e., it became permeable to green rays. Aq. solns. which would absorb all but definite wave lengths were interposed between the light and the dark stable soln.: chrysoidine (concd.), absorbs $682-625\mu\mu$, the phototropic soln. remains rose colored; chrysoidine (dil.), $682-582$, rose; chrysoidine + nitrosodimethylaniline, $672-558$, rose-yellow; brilliant green + nitrosodimethylaniline, $568-502$, lemon-yellow; brilliant green and crystal violet, $505-442$, gold-yellow; crystal violet, $475-400$, rose-yellow. The max. effect lies between $508-502\mu\mu$. The temp. coeff. was detd. by the method of P. and M., i. e., by the time necessary to produce a certain modification in the color. In this way the temp. coeff. for decoloration for $20-30^\circ$ was 1.20, $30-40^\circ$ 1.17, and $40-50^\circ$ 1.12. In the coloration reaction the velocity was found to be independent of the temp. E. J. W.

Scission of decahydroquinoline into its optical antipodes. II. L. MASCARELLI AND F. NIGRISOLI. Univ. Bologna. *Atti accad. Lincei* 23, II, 276-81 (1914); *Gazz. chim. ital.* 45, I, 1, 106-19 (1915).—Other compds. besides decahydro- β -naphthol (C. A. 6, 3096) have the peculiarity of occurring in a smaller number of stereoisomers than are theoretically possible. M. and N. state that this always occurs when in bicyclic compds. the 2 C atoms common to both nuclei (*i. e.*, 9 and 10) become asym. owing to the introduction of substituents. C atoms 9 and 10 must always show an opposite rotation in order to maintain the stability of the ring and accordingly the number of theoretically possible isomers is diminished by 2. Decahydroquinoline (*a*) fulfills the same requirements. The pure compd., m. 48.5°, b. 203-5°, was split as the *d*-bromocamphorsulfonate into the *d* and *l* optical antipodes. A mixt. of equal parts of the 2 antipodes of the free base as well as the hydrochloride showed the same properties as the original material, so that synthetic (*a*) must be a racemic mixt. (*a*) was synthesized according to Skita (C. A. 7, 2558) by reducing quinoline with H_2 + colloidal Pt. All reductions do not give (*a*) (cf. Skita, *Chem. Ztg.* 1914, 605). *d*-Decahydroquinoline *d*-bromocamphorsulfonate, needles from H_2O , m. 239-40°, sol. in hot EtOH and MeOH, also in AcOH and $CHCl_3$, $[\alpha]_D^{25}$ 69.53° (in 2.03% aq. soln.) and $[\alpha]_D^{25}$ 72.26° (in 0.80% aq. soln.), $[M]_D^{25}$ 320.0 (av.). *d*-Decahydroquinoline, $C_{10}H_{17}N$, compact, white mass, b. 200-2°, softens 70°, m. 75-6°, $[\alpha]_D^{25}$ 4.57° (in 2.84% EtOH soln.) and 4.75° (in 4.00% EtOH soln.), $[M]_D^{25}$ 6.69 (av.). The odor resembles that of the fatty acids and suggests peppermint oil, sol. in org. solvents, hygroscopic, absorbs CO_2 ; hydrochloride, crystals from H_2O , m. 303-4°, $[\alpha]$ in H_2O soln. is very small. *l*-Decahydroquinoline *d*-bromocamphorsulfonate is difficult to purify and showed somewhat variable physical consts. The purest product was obtained as crystals, m. 192°, $[\alpha]_D^{25}$ 61.3° (av. of a number of detns. in H_2O), $[M]_D^{25}$ 276.0 (av.). *l*-Decahydroquinoline, colorless highly refractive oil, b. 200-1°, solidifies on cooling into a cryst. mass, m. 74-5°, softens 70°, $[\alpha]_D^{25}$ -4.58° (in 7.31% EtOH soln.), $[M]_D^{25}$ -6.37°; the hydrochloride was obtained as tablets from $HCl \cdot H_2O$, m. 305°, blackens 300°; its optical rotation in H_2O is very small. Besides the above described salts considerable of a "rubbery" residue was obtained from the mother liquor from which other products have not been sepd. as yet.

E. J. WITZEMANN.

Scission of decahydroquinoline into its optical antipodes. III. L. MASCARELLI. Univ. Cagliari. *Atti accad. Lincei* 23, II, 281-3 (1914); *Gazz. chim. ital.* 45, I, 127-32 (1915); cf. preceding abstr.—Exact details on the fractional sepn. of the fractions obtained from *l*-decahydroquinoline *d*-bromocamphorsulfonate. The fraction, m. 175°, was taken as the product sought since the mol. refraction coincided with that calcd. from the components. M. ascribes the difficulty of purification of the product to the probable presence of 2 forms of *d*-bromocamphorsulfonic acid and cites observations of other authors in support of this. The small abs. rotation of the 2 decahydroquinolines is ascribed to the small asymmetry of the compds.

E. J. WITZEMANN.

Some new derivatives of azoxybenzene. BRUNO VALORI. Univ. Florence. *Atti accad. Lincei* 23, II, 284-92 (1914).—It was previously noted (C. A. 8, 79) that in detg. which of the 2 possible formulas $(PhN(:O):NC_6H_4R)$ and $(PhN:N(:O)C_6H_4R)$ represents the constitution of the azoxyphenols (*a*), the criteria used in the case of the azoxybenzenes (*b*) do not apply. The latter do not react with Br and the 2nd form does not react with HNO_3 but both forms of (*a*) react. In general (*a*) furnishes derivs. more easily than (*b*). Ordinary azoxybenzene in concd. AcOH soln. gives no NO_2 deriv. with cold HNO_3 (d. 1.48) but azoxyphenetole (*c*), $(EtOC_6H_4)_2N_2O$ gives a di- NO_2 compd. With (*a*) in $CHCl_3$ Br gives a mono-Br (*d*) and di-Br deriv. (*e*). (*d*) (m. 126°) reduced in EtOH-HCl with Sn gives *p*- $NH_2C_6H_4OEt$ and 4,2- $NH_2BrC_6H_4OEt$ (*f*), and is probably 3,4- $Br(EtO)C_6H_4N:N(:O)C_6H_4OEt$, (*e*) m. 153°, reduced similarly gives

2 mols. (f) so that it is $3,4\text{-Br(EtO)C}_6\text{H}_2\text{N}(\text{:O})\text{NC}_6\text{H}_5(\text{OEt})\text{Br}$. Another di-Br deriv., m. 165° , is formed in very small amts. HNO_3 acting on (c) in AcOH gives a mono- NO_2 deriv. (like (f)) m. 153° , and a di- NO_2 deriv. (like (e)) m. 185° . In order to further verify Angeli's expts. on azoxyphenol (g) the behavior of the Et deriv. was studied. $\text{Ph(N}_2\text{O)C}_6\text{H}_4\text{OEt}$, m. 72° , in AcOH gave with HNO_3 a compd. which seems to be $4,3\text{-HO(O}_2\text{N)C}_6\text{H}_2\text{N:NPh}$ and a mono- NO_2 deriv., $4,3\text{-EtO(O}_2\text{N)C}_6\text{H}_2\text{N:N(O)Ph}$, so that in this case too the NO_2 enters more easily into the nucleus attached to N free from O when OEt is substituted in it. (g), m. 156° , is thus $\text{PhN(O):NC}_6\text{H}_4\text{OH}$ and its di- NO_2 deriv., m. 197° , is probably $4,3,5\text{-HO(O}_2\text{N)}_3\text{C}_6\text{H}_2\text{N:N(O)Ph}$. The isomer of (g) is $\text{PhN:N(O)C}_6\text{H}_4\text{OH}$ (h), which is confirmed by the fact that its Et deriv. m. 75° , in AcOH gives with Br a dibromo deriv. which with Sn, etc., gives (f) and $1,4\text{-BrC}_6\text{H}_4\text{NH}_2$ and therefore is $3,4\text{-Br(EtO)C}_6\text{H}_2\text{N(O):NC}_6\text{H}_4\text{Br}$. In this case 1 Br enters the PhN: group according to the rule. The same isomer of (g) with HNO_3 in AcOH gives a mono- NO_2 deriv. (NO_2 adjacent to OH), m. 171° , and a little of an isomer m. 263° , and a di- NO_2 deriv., m. 185° . 1 g. (c) in 6 cc. CHCl_3 + 0.33 cc. Br_2 in 2 cc. CHCl_3 after standing 0.8 hr. was treated with NaHSO_3 , the CHCl_3 was removed, the residue taken up in EtOH and *monobromoazoxyphenetole*, yellow needles, m. 126° , was obtained. 1 g. of this, covered with EtOH, was heated 0.5 hr. with 3 g. Zn + 15 cc. of satd. EtOH-HCl. The EtOH was distd. off, the residue made alk. and distd. with steam. On acidifying the distillate with HCl white crystals of the hydrochloride of $p\text{-NH}_2\text{C}_6\text{H}_4\text{OEt}$ and (f) were sepd. from the more sol. part. The *dibromo derivative*, fine, yellow needles, m. 153° , was obtained by warming 4 g. of the mono-Br compd. with excess of Br_2 and purifying as above. 0.25 g. (c) dissolved in 25 cc. AcOH is cooled and treated with 10 cc. HNO_3 in 10 AcOH; *mononitroazoxyphenetole*, bright yellow needles, m. 153° , seps. The preceding (0.5 g.) in 30 cc. of 99% AcOH + 30 cc. HNO_3 in 20 cc. AcOH was thrown into H_2O after 15 mins. in order to sep. the *dinitro derivative*, yellow cryst. powder, m. 185° . 0.6 g. of the Et deriv. of (g) in 3 cc. of 99% AcOH + 3 cc. HNO_3 in 2 cc. AcOH seps. *mononitroethoxyazobenzene*, yellow needles, m. 128° . 1 g. of this covered with 8 g. concd. H_2SO_4 on the H_2O bath 5 mins. and thrown into H_2O seps. *mononitrohydroxyazobenzene*, red-yellow cryst. powder, m. 129° . (g) m. 150° (0.9 g.), in 5 cc. AcOH + 3 cc. HNO_3 in 3 cc. AcOH pptd. *dinitroazoxyphenol*, golden-yellow needles, m. 197° . Ethoxyazoxybenzene, m. 75° , (0.5 g.) in 14 cc. AcOH + 1.6 cc. Br_2 in 2 cc. AcOH pptd. *dibromoethoxyazoxybenzene*, colorless powder, m. 135° . 0.5 g. of (h), m. 117° , in 5 cc. of 99% AcOH + 1.5 cc. HNO_3 in 1.5 cc. AcOH ppts. *mononitroazoxyphenol*, minute needles, m. 171° (NO_2 adjacent to OH). E. J. W.

The iso-oleic acid of the seeds of ivy. F. C. PALAZZO AND A. TAMBURELLO. Florence. *Atti accad. Lincei* 23, II, 352-6 (1914).—In a preceding paper (*Arch. farm.* No. 15 (1913)) a nonsatd. acid in the form of its glyceride was noted as constituting the major part of the fatty material in these seeds. It was thought to be erucic acid. More material has been obtained and it was found to be iso-oleic acid (a). The fats constitute 30-32% of the wt. of the air-dried seeds, m. 25.2° , f. 21.4° , n_D^{20} 1.402, acid no. 3.99, sapon. no. 190.5, I no. 91.8. Of the Pb salts 70-80% is insol. in dry Et_2O and this constitutes the iso-oleic acid salt. Recrystd. from hot EtOH, decompd. with HCl, etc., the various fractions showed uniform characteristics; m. $29\text{-}30^\circ$ (erucic acid m. $33\text{-}4^\circ$); b_{10} 254.5° , i. e., the b. p. of oleic acid (erucic, b_{18} $237\text{-}8^\circ$). The I no. and acid no. of the purified acid are 89.85 and 200.1, resp., as compared with the calcd. values, 90 and 198.5. The analysis of the Pb salt corresponds to that of Pb oleate. 2.6 g. of the acid in 100 cc. of 95% EtOH in the presence of Pd black absorbed the calcd. amt. of H_2 in a few mins. and deposited shining laminas of stearic acid, m. $69\text{-}70^\circ$, b_{18} 232° , acid no. 194.9. Of the known iso-oleic acids petroselinic acid (b), $\text{HO}_2\text{C(CH}_2)_4\text{CH:CH(CH}_2)_8\text{Me}$, m. $33\text{-}4^\circ$, f. 27° , and an iso-oleic acid, $\text{HO}_2\text{C(CH}_2)_{10}\text{CH:CH}$

(CH_2I_2 Me, of Fokin (C. A. 6, 2409), m. $34-5^\circ$; the b. ps. are not given. Fokin obtained 2 dihydroxystearic acids, m. 122° and $85-8^\circ$, resp., on oxidizing (c). The acid (a) oxidized with KMnO_4 gave the same HO acid, m. 122° , acid no. 178. Likewise with HNO_3 (a) gave the corresponding stereoisomer while F.'s acid remained unchanged. The elaidinic acid obtained m. 54° , which is identical with that of the isomer of (b) (Vongerichten, Köhler, Ber. 42, 1638(1908)); acid. no. 200.2, calcd. 198.5. The d_{40} 0.8700 and n_{40} 1.4533 of (a) coincide with the values observed for (b) so that the only difference is the m. p. and P. and T. think this is due to a difference in technique in detg. the m. p. and describe their own carefully. It is concluded that (a) and (b) are identical. The Et_2O -sol. portion of the Pb salts was composed of the ordinary Pb oleate containing a little of some less satd. acid. The pure oleic acid was isolated and identified. It was thus shown the oleic acid can occur in nature along with petroleic acid.

E. J. WITZEMANN.

Vanadylsalicylates. G. A. BARBIERI. Univ. Ferrara. *Atti accad. Lincei* 23, II, 408-11(1914); cf. C. A. 9, 617.—The vanadyl radical reacts to give vanadylsalicylates, $\text{OV}(\text{OC}_6\text{H}_4\text{CO}_2\text{M})_2$, analogous to the cuprisalicylates (Piria, Ann. 93, 262 (1855); Ley, Erler, C. A. 2, 2079) and the palladosalicylates (C. A. 9, 298). While the common vanadyl salts are green or blue, the vanadyltartrates are violet and the salicylates are white or yellow as solids and green in soln. The aq. solns. of alkali vanadylsalicylates with sol. salts of Ca, Ba, or Tl ppt. the corresponding vanadylsalicylates (a) as white cryst. powders. The Tl salt is anhydrous; the others are hydrated. The Ag salt was not obtained because AgNO_3 was reduced by VO and Ag was pptd. (a) are stable, can be recrystd. from H_2O and are not decompd. by weak alkalis. The stability of (a) is thought to depend on the same cause as in the case of the tartrates and their constitution is analogous to that assigned to the chromioxalates by Werner. *m*- and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ do not form complexes with Cu, Pd, or VO and it is thought that because the OH is farther from the CO_2H than in the *o*-deriv. it is more difficult to establish the secondary union between the metal and the HO and CO_2H groups. The same difficulty has been observed with the NH_4 acids in which NH_4 is β or γ to the CO_2H . 5 g. NH_4VO_3 in 50 cc. 20% H_2SO_4 was reduced with a stream of SO_2 , the excess of SO_2 was removed by boiling the soln. neutralized with NH_3 . 25 g. $\text{HOC}_6\text{H}_4\text{CO}_2\text{NH}_4$ in 100 cc. H_2O were added and NH_3 to make the mixt. alk. On cooling ammonium vanadylsalicylate, $\text{OV}(\text{OC}_6\text{H}_4\text{CO}_2\text{NH}_4)_2 \cdot 3\text{H}_2\text{O}$, seps. as white crystals, little sol. in cold H_2O ; NH_4 salts reduce its solubility. 5 g. NH_4VO_3 were calcined to remove NH_3 , dissolved in HCl, reduced with SO_2 , etc., neutralized with K_2CO_3 and treated with 20 g. *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ + 15 g. K_2CO_3 in 150 cc. H_2O ; on cooling potassium vanadylsalicylate, $\text{OV}(\text{OC}_6\text{H}_4\text{CO}_2\text{K})_2$, seps. The NH_4 salt + CaCl_2 gives calcium vanadylsalicylate, $\text{OV}(\text{OC}_6\text{H}_4\text{CO}_2)_2 \cdot \text{Ca} \cdot 3\text{H}_2\text{O}$. Similarly thallium vanadylsalicylate, $\text{OV}(\text{OC}_6\text{H}_4\text{CO}_2\text{Tl})_2$, was obtained.

E. J. WITZEMANN.

The bases formed on alkylating pyrroles. G. PLANCHER AND BRUNO TANZI. Univ. Parma. *Atti accad. Lincei* 23, II, 412-7(1914).—P. and Ravenna have recently (C. A. 8, 1763) taken up the study again of the bases formed by the action of alkyl iodides on pyrroles, and have stated that they are constituted like the indoles: i. e., may be pyrrolenine or methylenepyrroline. P. and Zambonini (C. A. 8, 1764) found that MeI acting on $\text{C}_4\text{H}_5\text{NMgX}$ in the presence of K_2CO_3 gave $\text{C}_4\text{HMe}_2\text{N}$ + MeI. Oddo and Nameli (C. A. 8, 1272) thought that $\text{C}_4\text{H}_5\text{NMgBr}$ + MeI form dihydropyridine but could not sep. it. P. and Z. studied the action of CHCl_3 on $\text{C}_4\text{HMe}_2\text{N}$ and believed that evidence for the pyrrolic formula was found, analogous to the earlier results with indole (P. and Carrasco, *idem* 14, I, 62, 704, etc.). All properties of the new bases are analogous to those of indolenine but a formula has not yet been assigned. The expts. on the alkylation of pyrrole are continued. 4.35 g. Mg +

29 g. MeI + 17 g. 2,5- $C_4H_7Me_2N$ in Et_2O gave a deriv.; the Et_2O was evapd. and 35 g. iso-PrI was added and the mixt. boiled 18 hrs. The aq. acid soln. was extd. with Et_2O and the Et_2O residue fractionated under 16 mm.: (1) 3 g. b. $90-103^\circ$; (2) 4 g. $103-8^\circ$; redistd. in air a fraction b. $216-7^\circ$ was found to be 2,5-dimethyl-3-isopropylpyrrole (a). Iso-PrNH₂ condensed with $(CH_3CO_2Et)_2$ in AcOH gave diethyl N-isopropyl-2,5-dimethylpyrrole-3,4-dicarboxylate, which when sapond. in dil. KOH gave the free acid, m. 200° (decompn.) and the latter distd. gives $\alpha, \alpha', N-Me_2(C_4H_7)C_4H_2N$, b. $182-3^\circ$, which differs from (a), thus proving (a) to be the 3-iso-Pr instead of the N-iso-Pr compd. The soln. extd. with Et_2O was made alk. and distd. with steam; a base, $C_{12}H_{19}N$, b₁₀ $86-110^\circ$, seps.; the picrate $C_{18}H_{23}N_5O_7$, m. $173-4^\circ$. An isomeric picrate, m. 107° , was also obtained, of which the free base has a marked camphor-like odor. These isomers are dimethyldiisopropylpyrrolenine, i. e., $(C_4H_7)_2C.CH.CMe.N:CMe$ or

$C_4H_7C.CH.CMe.N:CMe(C_4H_7)$. The product from 1.2 g. Mg + 6 g. MeI + 6 g. C_4H_7-

Me_2N reacting with 8.4 g. iso-PrI and boiled 12 hrs. finally gave the hydrochloride and picrate, m. $152-3^\circ$, of a base, $C_{11}H_{19}N$; with an odor like menthol, which is tetramethylisopropylpyrrolenine, i. e., either $C_4H_7(Me)C.CMe:CMe.N:CMe$ or

$MeC:CMe.CMe:NCMeC_4H_7$. The product from 31 g. EtBr + 5.55 g. Mg + 16.5

g. C_4H_9N (b. $130-1^\circ$), treated with 38.8 g. MeI and boiled 4 hrs., gave 3 fractions from the Et_2O ext. of the acid aq. soln.: (1) 1 g. b. $100-25^\circ$; (2) 6 g. b. $125-35^\circ$; (3) 0.5 g. b. $135-48^\circ$. Much of the C_4H_9N remained unchanged. The picrate, m. $218-9^\circ$, of a base, $C_7H_{12}N$, was sepd., i. e., trimethylpyrrolenine, either $MeC:C.CH:N.CMe_2$ or

$Me_2C.CH:CH.N:CMe$. The product from 2.2 g. Mg + 14.23 g. EtI + 10 g. 2,3,5-

$C_4H_7NMe_2$ was boiled 18 hrs. with 14.3 g. EtI. The Et_2O ext. of the acid aq. soln. gave back most of the pyrrole deriv. unchanged but the soln. from the Et_2O extn. gave finally 10 g. of a picrate, m. $199-200^\circ$, of a base, $C_9H_{14}N$, having a refreshing odor. A small amt. of another impure base was sepd., which is $EtMeC.CH:CMe.N:CMe$ or

$MeC:CH.CMe:N.CEtMe$. Hess and Wissing (Ber. 37, 1420) found $C_8H_{12}N$ here

which seems to be wrong. The product from 3.95 g. Mg + 23 g. MeI + 20 g. $\alpha, \alpha'-Me(iso-Pr)C_4H_7N$ was boiled 17 hrs. with 23 g. MeI and gave finally a picrate, m. $121-2^\circ$, of a base, $C_{10}H_{17}N$, with a refreshing odor, which is a trimethylisopropylpyrrolenine, i. e., one of 4 possible isomers. It has thus been shown that using the MgX deriv. (1) C_4HMe_2N gives a base with 1 more alkyl with MeI and iso-PrI; (2) 2,3,5- $C_4H_2Me_3N$ gives a base with 1 more alkyl; (3) $\alpha, \alpha'-C_4H_7Me_2N$ gives a base with 1 more alkyl; (4) $\alpha, \alpha'-C_4H_7Me(C_4H_7)N$ gives a base with 2 more alkyls; (5) C_4H_9N gives a base with 3 more alkyls. It was therefore shown that it is not necessary to methylate pyrrole completely in order to obtain these bases. E. J. WITZEMANN.

Vicinal 1,2,3-trinitrobenzene: a new trinitrotoluene and the corresponding dinitrohalogen substitution products. G. KÖRNER and A. CONTARDI. *Atti accad. Lincei* 23, II, 464-71 (1914).—Of the 3 $C_6H_3(NO_2)_3$, required by the theory only the 1,3,5- and 1,2,4-derivs. are known and all attempts to obtain the 1,2,3-deriv. have failed. It was easily obtained by substituting NO_2 for NH_2 in 2,6- $(O_2N)_2C_6H_3NH_2$, (a), m. 137.8° . 18 g. (a) suspended in 45 cc. HNO_3 (d. 1.38) was satd. at 0° with N_2O_5 , the excess N_2O_5 removed with an air current and most of the diazo nitrate (very explosive) was pptd. Crushed ice (45 cc.) was added and the ppt. collected on a Pt cone and washed with a little ice- H_2O . A soln. of 90 g. $CuSO_4.5H_2O$ + 30 g. $NaNO_2$ per l. was

prepd. The nitrate suspended in a l. of ice- H_2O was poured into 5 kg. crushed ice and then rapidly treated with the CuSO_4 soln.; a white cryst. mass seps. and N is evolved. After 12 hrs. 1,2,3-trinitrobenzene (b), white laminas from EtOH, m. 127.5° , was filtered off. EtOH- NH_3 reacts in the cold with (b) to give (a) even more easily than the sym. deriv. KOH or NaOH gives the corresponding o-dinitrophenolate. (b) may also be obtained by pouring the diazotization mixt. into 120 g. NaNO_2 in H_2O + 5 kg. ice. In both processes 18 g. (a) give 16 g. (b). 3 isomers of $\text{MeC}_6\text{H}_3(\text{NO}_2)_3$ are known but the 4th has never been encountered either in the lab. or commercially. By using 20 g. 4,3,5- $\text{H}_3\text{N}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{Me}$, m. 168° , and treating with 50 g. HNO_3 (d. 1.38) and working by the 1st method as with (a), 3,4,5-trinitrotoluene (c), colorless laminas, m. 137.5° , was obtained (yield 60%). The 2nd method gives a 60% yield in this case too. (c) reacts at once with alks., and with EtOH- NH_3 gives the parent PhNH_2 deriv. 550 g. H_2SO_4 (d. 1.8) at 60° are treated with 10 g. (c) and then at the same temp. gradually with 14 g. CrO_3 and kept at 60° for 16 hrs. This was poured into ice and the temp. was kept below 10° . The cryst. ppt. (9 g.) was 3,4,5-trinitrobenzoic acid, (d), opaque white needles from Et $_2\text{O}$, m. 168° (decompn.). Boiled, with H_2O (d) evolved N_2O_5 vapors and gave 4,3,5- $\text{HO}(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{CO}_2\text{H}$, m. 236° . In excess of NH_3 (d) gives the NH_4 salt of chrysanic acid. In abs. MeOH (d) at 110° gives dinitroanistic acid. These properties prove its constitution and show why these derivs. are not obtained by ordinary nitration. Heated, (d) loses CO_2 to give (b). The diazo nitrate of (a) suspended in H_2O and poured on CuCl soln. (25 g. H_2O + 12 g. NaCl + 100 g. conc. HCl + excess Cu, about 20 g.) and then into crushed ice, evolves N and ppts. 2,6- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Cl}$, yellow prisms from EtOH, m. 88° , identical with that obtained by Borsche and Rantscheff (*Ann.* 379, 152). A better result is obtained by pouring the diazotization mixt. into an excess of CuCl_2 soln., etc. Using CuBr 1-bromo-2,3-dinitrobenzene (e), yellow prisms, m. 107° , is obtained. With EtOH- NH_3 in a sealed tube at 150° (e) gives (a). With CuBr_2 a better yield (22 g. of (e) instead of 9 g. from 18 g. (a)) is obtained. Treating the diazonium nitrate of (a) with KI gives 2,6- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{I}$ (identical with a prepn. previously obtained by K.). In the same way were obtained the corresponding 4-chloro-3,5-dinitrotoluene, bright yellow needles, m. 114.5° ; 4-bromo-3,5-dinitrotoluene, yellow prisms, m. 118.4° ; and 4-iodo-3,5-dinitrotoluene, lemon-yellow needles, m. 158° . The best yield was obtained by the CuX_2 method. With EtOH- NH_3 the aniline was regenerated.

Strychnine and brucine. R. CIUSA AND L. VECCHIOTTI. Univ. Bologna. *Atti accad. Lincei* 23, II, 480-3 (1914).—C. and Scagliarini (*C. A.* 6, 3270) showed that isostrychnine with Br in glacial AcOH and subsequent treatment with boiling EtOH gives the compound (a), $\text{HBr.C}_{20}\text{H}_{21}\text{NBr}_3(:\text{NH})\text{CO}_2\text{Et}$. The supposition that the deriv. is a hydrobromide is supported by the fact that by treatment with NH_3 the free base, $\text{C}_{20}\text{H}_{21}\text{NBr}_3(:\text{NH})\text{CO}_2\text{Et}$, colorless needles, sol. in acids and EtOH, was obtained. The chloroaurate, $\text{C}_{20}\text{H}_{17}\text{O}_2\text{N}_3\text{Br}_3.\text{HAuCl}_4$, was obtained as yellow needles, difficultly sol. in H_2O . When (a) is treated with dil. NaOH and then with dil. NH_3

a mixt. of Br derivs. is obtained from which the hydrobromide $\text{HBr}(\text{C}_{20}\text{H}_{21}\text{NBr}_3) \begin{array}{c} \diagup \text{CO} \\ | \\ \diagdown \text{N} \end{array}$

was isolated by extg. with boiling dil. HBr; yellow scales containing 1 mol. of H_2O of crystn. Brucine treated with HNO_3 gives cacotheline (b), the nitrate of the nitrated base $\text{C}_{20}\text{H}_{21}(\text{NO}_2)_3\text{O}_2\text{N}_3$. (b) treated with $\text{NH}_4\text{OH.HCl}$ + Na_2CO_3 gives a dioxide, $\text{C}_{20}\text{H}_{19}\text{O}_4\text{N}_3(:\text{NOH})_2.3.5\text{H}_2\text{O}$, gold-yellow needles, m. $319-20^\circ$, sol. in alkalis and acids, insol. in org. solvents. This deriv. is to be studied further. E. J. WITZEMANN.

Aromatic nitro derivatives. II. Trinitrobenzoic acid and dinitrotoluidine corresponding to β and γ -trinitrotoluenes. MICHELE GIUA. Milan. *Atti accad. Lincei* 23,

II, 484-90(1914).—The $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{Me}$ (α, β, γ) are as yet imperfectly known. The sym. α -deriv. has acquired great importance as a substitute for picric acid in explosives, and the β - and γ -derivs. were studied by Hepp (*Ann.* 215, 366 (1882)). Will (cf. *C. A.* 8, 1590) detd. the constitution of the β -deriv. as 2,3,4- $(\text{NO}_2)_3\text{C}_6\text{H}_2\text{Me}$. W. found that it is formed on nitrating either 2,3- or 3,4- $(\text{O}_2\text{N})_2\text{C}_6\text{H}_2\text{Me}$ and that with $(\text{NH}_4)_2\text{S}$ it gives dinitrotoluidine. Of the possible $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$ only the sym. deriv. is known which was derived from the α -deriv. above. This acid is important because with it Meyer's esterification law was established experimentally. The $(\text{O}_2\text{N})_3\text{C}_6\text{H}_2\text{CO}_2\text{H}$ to be described were derived from the β - and γ -derivs. and give esters easily under normal conditions, which agrees fully with W.'s results and excludes the possibility of 2 NO_2 groups being *o*- to the Me in the β -deriv. W. found that the β - and γ -derivs. give different colors with NH_3 which change later in acetone. G. found that an NO_2 is substituted by NH_3 . The corresponding dinitrotoluidines (*a*) may be obtained in this way (Körner, Laudenhimer). The 1st phase is thought to be due to the formation of an addition product which gradually undergoes changes to give (*a*), having a different color. The β - and γ -derivs. were obtained by nitrating 100 g. *m*- $\text{NO}_2\text{C}_6\text{H}_4\text{Me}$ in 250 g. of a mixt. of anhydrous HNO_3 - H_2SO_4 (30% HNO_3) on a boiling H_2O bath for 6 hrs., and pouring into ice and H_2O ; there was formed 140 g. of oil (di- NO_2 -derivs.) which was placed in 500 g. of HNO_3 - H_2SO_4 mixt. and heated 6 hrs. The mixt. of β - and γ -derivs. obtained was recrystd. and gave finally not more than 15% of β -compd. 2.5 g. of the β -deriv. in 8 cc. HNO_3 (d. 1.52) at 150 - 60° in a sealed tube for 6 days and 1 day at 210° gave 2,3,4-trinitrobenzoic acid (*b*), prisms, m. 202 - 3° , loses CO_2 at 219° . 5 g. β -deriv. in 200 cc. concd. H_2SO_4 + 6 g. CrO_3 added gradually, and heated at 50 - 60° for 4 hrs. and then poured on ice seps. (*b*) and gives it more easily. (*b*) is very sol. in EtOH and AcMe, less so in H_2O and C_6H_6 . With excess of alkali (*b*) gives a red color. 2 g. (*b*) in 10 cc. EtOH (95%) + 1.5 cc. concd. H_2SO_4 boiled for 10 mins. seps. the ethyl ether, m. 79 - 80° . The H_2O soln. of (*b*) with AgNO_3 ppts. the silver salt, $\text{C}_7\text{H}_2\text{O}_2\text{N}_3\text{Ag}$, yellows in the air, explodes violently 230° . 4 g. of the γ -deriv. similarly treated with HNO_3 gave 2,4,5-trinitrobenzoic acid (*c*), brilliant laminas, m. 190 - 1° (loss of CO_2); also obtained by oxidizing with CrO_3 - H_2SO_4 . (*c*) gives a red-yellow color with alkalis. Boiled with 15 cc. EtOH + 1.5 cc. H_2SO_4 15 mins. 2 g. (*c*) gave the ethyl esters, shining laminas, m. 84° ; similarly the methyl ester, m. 102° , was obtained. The silver salt is also explosive on warming. 1.14 g. of the β -deriv. in 15 cc. acetone + 1.7 cc. NH_4OH (17%) gives a green color which becomes red in some hrs. Poured into H_2O after some days a compd., $\text{C}_7\text{H}_7\text{O}_2\text{N}_3$, needles, m. 93 - 4° , seps. 2.27 g. of the γ -deriv. similarly treated gave a compd., $\text{C}_7\text{H}_7\text{O}_2\text{N}_3$, needles, m. 192 - 3° .

E. J. WITZEMANN.

The Walden inversion. CECIL L. HORTON. *Chem. News* 111, 29-41(1915); cf. *C. A.* 8, 679.—A theory is advanced to explain the mechanism of this inversion. It is based on the formation of an additive intermediate product and on a consideration of the attraction or otherwise of the $-\text{CO}_2\text{H}$ and other groups involved, for the addendum. The case of the differing action of KOH on a chloro monobasic acid, where inversion does not occur, and on a di-acid, such as *d*-chlorosuccinic acid, where inversion results, is treated of. The action of Ag_2O is also considered, as well as the actions of HNO_3 and NOCl on NH_2 acids. For a complete discussion of the theory reference should be made to the original article as it is hardly suitable for abstracting.

NORMAN A. SHEPARD.

Aliphatic diazo compounds. H. STAUDINGER. Zürich. *Z. angew. Chem.* 27, I, 354-5(1914).—A whole series of new representatives of this at present relatively small class of compds. may be prepd. by the oxidation of the hydrazones of aldehydes and ketones. The products are diazo compds. and not tetrazones, as Curtius thought.

MeCN_2 and PhMeCN_2 could not previously be obtained in a pure condition and though diazo compds. containing only aromatic rests, like Ph_2CN_2 (a) and $(\text{MeC}_6\text{H}_4)_2\text{CN}_2$ (b), were previously isolated, they were considered to be very unstable. These substances are well crystd. and strongly colored. (b) resembles KMnO_4 . These new diazo compds. do not show all the reactions of $\text{N}_2\text{CHCO}_2\text{Et}$ because of their greater tendency to split off N. Of the new reactions observed, the behavior toward COCl_2 is most interesting. α -Chloro-substituted acid chlorides are thus formed, which can be converted into ketenes by the removal of halogen. (a) is thus converted into $\text{Ph}_2\text{CClCOCl}$ and finally into $\text{Ph}_2\text{C:CO}$. With $(\text{COCl})_2$ either $\text{ClCH}_2\text{COCO}_2\text{H}$ derivs. or α -diketones are formed, e. g., $\text{Ph}_2\text{CClCOCOC}$ from (a) and $(\text{COCH}_2\text{Cl})_2$ from CH_2N_2 . By the action of CSCl_2 substances of the compn. of thio-acid chlorides are obtained. These compds., however, have none of the properties of such substances. They do not give thioketenes with metals, but are converted into dichloroethylene derivs. (a) apparently gives $\text{Ph}_2\text{C:CClSCl}$, which is converted into $\text{Ph}_2\text{C:CCl}_2$ with the sepn. of S. It is a question whether CSCl_2 does not react here in its tautomeric form Cl.C.SCl . These thio compds. are colorless, while *thiobenzoyl chloride*, which was prepd. for comparison, is highly colored and shows the normal reactions of acid chlorides. Interesting results were obtained by the action of unsatd. substances on diazo compds. Nascent CO, from Ni(CO)_4 , gave no ketene, even at high pressure. By the action of SO_2 on (a) a sulfene $\text{Ph}_2\text{C:SO}_2$ was first formed, which could not be obtained in a pure state. It was identified by conversion into its Me ester, $\text{Ph}_2\text{CHSO}_2\text{Me}$. The free sulfene could not be obtained pure because it either reacted with H_2SO_4 , forming BzPh , or with the excess of (a), forming an addition product which readily loses N and SO_2 with the formation of $(\text{Ph}_2\text{C:})_2$.

NORMAN A. SHEPARD.

Colchicine. III. The study of several cleavage products. A. WINDAUS. *Innsbruck. Sitzb. Heidelberger Akad. Wiss.* [18] 1914, 9 pp.; through *Chem. Zentr.* 1914, II, 1455; cf. *C. A.* 5, 3417, 3418. I. The action of potassium permanganate on colchicine. The $(\text{MeO})_3\text{C}_6\text{H}(\text{CO}_2\text{H})_2$ obtained by the action of hot KMnO_4 soln. on colchicine is not 3,5,6-trimethoxy-*o*-phthalic acid, as previously stated, but must be the 3,4,5-acid. This conclusion is drawn from the work of Voswinkel and de Weerth (*C. A.* 6, 2604) and of Bargellini and Molina (*C. A.* 6, 3271) and also from the fact that the acid from colchicine is converted into gallic acid by boiling HI. II. The action of potassium permanganate on colchicinic acid. This acid, $(\text{HO})_3\text{C}_6\text{H}_2\text{O}(\text{OH})\text{-NH}_2$, is converted by hot KMnO_4 into oxalic and succinic acids. This latter acid, along with a very small amt. of picric acid, is also obtained by oxidation of colchicine with HNO_3 . III. The behavior of colchicine with molten caustic potash. After heating colchicine with 6 times its wt. of KOH and a small amt. of H_2O at 220° and then at 245° , the melt is dissolved in water. On treating this aq. soln. with hot concd. KMnO_4 , both terephthalic and trimellitic acids are formed. Colchicinic acid, treated in the same manner, also gives these same acids. This indicates that there is present in colchicine, besides the pyrogallol ring, a 2nd ring, which is broken down by oxidation, giving terephthalic and trimellitic acids.

NORMAN A. SHEPARD.

Colchicine. IV. The action of iodine and caustic potash on colchicine. A. WINDAUS. *Sitzb. Heidelberger Akad. Wiss.* [18] 1914, 9 pp.; through *Chem. Zentr.* 1914, II, 1455-6; see preceding abstr.—(Exptl. work by L. Krellwitz.) By treating colchicine in cold dil. NaOH with I in KI at a low temp., both oxidation and iodation take place with the formation of the compound $\text{C}_{10}\text{H}_{22}\text{O}_6\text{NI}$ (a), according to the equation: $\text{C}_{10}\text{H}_{22}\text{O}_6\text{N} + 4\text{I} + 5\text{NaOH} = (\text{a}) + 3\text{NaI} + \text{Na}_2\text{CO}_3 + 3\text{H}_2\text{O}$. The group $-\text{COH}$ is thus replaced by I. The new substance, unlike colchicine, does not give the FeCl_3 reaction and thus does not contain the enol group. Replacement of the I by H does not restore the enol character. Of the five atoms of O then, 3 are linked in MeO groups,

1 in the Ac rest on the N, and the 5th as an —OH group. (a) seps. in pointed prisms from alc., m. 228–30°, difficultly sol. in dil. Na_2CO_3 , but sol. in cold dil. NaOH. If the resulting soln. is dild. and heated to boiling, hydrolysis occurs, with the sepn. of (a) unaltered. This substance is therefore a very weak acid. Though the I is not removed by boiling KOH, it is easily replaced by H by reduction with Zn dust and AcOH. The resulting product, $\text{C}_{19}\text{H}_{21}\text{O}_4\text{N}$, seps. from dil. alc. in needle-like prisms, m. 150° (decompn.). It contains H_2O of crystn., which is with difficulty removed; after drying, it m. above 200°, is easily sol. in dil. alkalies, only slightly sol. in Na_2CO_3 and dil. acids. Boiling alc. HCl removes AcOH, with the formation of the salt $\text{C}_{19}\text{H}_{21}\text{O}_4\text{N} \cdot \text{HCl}$, which seps. in leaves shriveling above 200° and m. 241°. The Ac rest has thus been removed from the N, leaving the NH_2 group in the form of its hydrochloride. (a) gives with Ac_2O an Ac deriv. m. 144–5°.

NORMAN A. SHEPARD.

The constitution of anemonin. YASUHIKO ASAHINA. Univ. Tokyo. *J. Pharm. Soc. Japan* 1915, No. 396; cf. C. A. 8, 1780.—To the cold soln. of 2 g. anemonin (a) in 20 cc. 0.5N KOH, 1% KMnO_4 was added with violent agitation until the color persists (about 640 cc.). The temp. was not allowed to rise above 3°. (Under these conditions $(\text{CH}_3\text{CO}_2\text{H})_2$, the chief product isolated by H. Meyer on oxidizing (a) with KMnO_4 , is not obtained.) After filtering from MnO_2 , the soln. was decolorized with NaHSO_3 , almost neutralized with dil. H_2SO_4 and then concd. until K_2SO_4 began to sep. This residue was extd. 7 times with AcOEt , dried over Na_2SO_4 and evapd. $\text{CO}(\text{CH}_3\text{CH}_2\text{CO}_2\text{H})_2$; (b) sepd. from the concd. soln. in yellow radiating leaves. Yield, 6 g. from 30 g. (a). After 1 recrystn. from AcOEt and decolorization with bone-black in Et_2O , it seps. pure in rhombic crystals. With $\text{NH}_2\text{CONHNH}_2 \cdot \text{HCl}$ in concd. H_2O soln. (b) gives a semicarbazone which seps. in prisms on the addition of AcONa soln. This product, m. 204°, is difficultly sol. in most organic solvents and is especially valuable for identifying this acid. The formation of (b) cannot be explained by H. Meyer's formula for (a). (*Monatsh.* 20, 634.) A. considers this substance to have a dilactone and not an anhydride structure and assigns to (a) formula (I). This structure

(I)

(II)

(III)

accounts for the formation of (b), the addition of 4 ats. H, and the optical inactivity (the formula is sym.) of (a). By hydrolysis of the lactone ring, anemoninic (II) and anemonic (III) acids are formed.

NORMAN A. SHEPARD.

Inversion of sucrose by invertase. IX. Is the reaction reversible? C. S. HUDSON AND H. S. PAINE. Bur. Chem., Dept. Agr. *J. Am. Chem. Soc.* 36, 1571–81 (1914); cf. C. A. 9, 1342.—A soln. of the enzyme invertase which was prepd. by the rapid autolysis of yeast under the influence of PhMe, and purified by clarification with neutral $(\text{AcO})_2\text{Pb}$ and H_2S , and by subsequent dialysis, was allowed to act upon aq. invert sugar solns. which were maintained at various degrees of slight alkalinity and acidity in an attempt to detect a possible synthesis of sucrose by the enzyme. Although numerous expts. under various conditions were tried, not one showed any indication

of such a synthesis. A repetition of Osaka's expts. (*J. Coll. Sci., Imp. Univ. Tokyo*, 25, Art. I), which indicate the synthesis of sucrose from invert sugar in concd. soln., in the presence of HCl, shows that the change of polariscopic rotation which he observed is not due to synthesis, but is caused by the decomg. action of the acid upon fructose. A repetition of similar expts. by Visser (*Z. physik. Chem.* 52, 275) shows that his supposed synthesis of sucrose was only a change in rotation which is caused by the influence of HCl upon the rotatory power of fructose. An exam. of the expts. of Kohl (*Bot. Centr., Beih., Abt. I* 23, 64f-64o) and of Pantanelli (*C. A.* 1, 3025) on the synthesis of sucrose by the action of invertase upon invert sugar solns. shows the exptl. evidence to be very doubtful. Invertase from yeast accomplishes a complete hydrolysis of sucrose to yield invert sugar; the reaction does not establish a mobile equil. and is not a reversible or balanced reaction within the limits of detection.

H. S. PAINE.

Presence of a glucoside in the sunflower. AUGUSTO ZANOTTI. Bologna. *Boll. chim. farm.* 53, 4-5 (1914).—Sunflower leaves with the stems were cut into small pieces if green, or coarsely ground if dry, and extd. with H₂O (4 parts of H₂O for the green and 10 parts for the dry leaves). This soln. was filtered and the residue was extd. anew with H₂O, the 2nd ext. being added to the 1st; the mixt. was then defecated with basic Pb acetate and the excess of the latter was removed as PbSO₄ (addition of H₂SO₄) in large measure, the last traces being pptd. by H₂S. After 24 hrs. a considerable excess of 95% EtOH was added to the liquid (pptn. of a white, amorphous ppt. of Ca salts), the latter was rendered slightly alk. with Na₂CO₃, the alc. was removed by distn. and the remaining aq. soln. was slowly evapd. to dryness on a sand bath. The residue was dissolved in 96% alc. and the soln., after filtration, was again evapd. to dryness. The final, brown-colored residue, which was composed in great part of a glucoside, was deliquescent, sol. in H₂O and in alc. and insol. in Et₂O; its aq. soln. was alk. This soln. reduced NH₃-AgNO₃ after the addition of NaOH or KOH; after boiling with a dil. acid it reduced Fehling soln., as well as alk. Bi subnitrate. No reaction was observed with picric and tannic acids; a light blue ppt. was obtained with CuSO₄, and dil. Fe₂Cl₃ gave a red ppt. which redissolved with the production of an orange soln. Neutral (AcO)₂Pb caused a white ppt. The action of caustic alkalies and heat caused the soln. to assume a dark yellow color. A characteristic odor was evolved when K₂Cr₂O₇ and H₂SO₄ were added to the soln. Z. suggests the tentative formula C₁₁H₁₈O₆N₂ for the glucoside.

H. S. PAINE.

Optically active *N*-monomethyl derivatives of alanine, leucine, phenylalanine and tyrosine. EMIL FISCHER and WERNER LIFSCHITZ. Univ. Berlin. *Ber.* 48, 360-78 (1915); cf. *C. A.* 7, 2541; 9, 1057.—*p*-Toluenesulfonyl-*d*-alanine, obtained in 67% yield from 18 g. *d*-alanine in 110 cc. of 2 *N* NaOH shaken with 76 g. MeC₆H₄SO₃Cl in 200 cc. Et₂O and treated at 1 hr. intervals with 3 100-cc. portions of the same NaOH, the Et₂O removed after 4 hrs. shaking, the filtered aq. soln. satd. with 5 *N* HCl and the resulting oil seeded and allowed to stand 15 hrs. in the ice chest, needles from 13 parts H₂O, sinters about 130°, m. 134-5° (the m. ps. given are cor.), yields beautifully cryst. quinine and brucine salts, $[\alpha]_D^{20}$ in alc. -6.81°, and of the acid recovered from the quinine salt recrystd. 3 times from H₂O -7.26° (cf. Gibson, *C. A.* 9, 612, who calls his compd. an *l*-deriv.). Its hydrolysis requires long heating with conc. HCl at 100°, but there is no marked racemization; the *d*-alanine recovered after 8 hrs. with HCl of d. 1.19 showed $[\alpha]_D^{20}$ 9.5°. From 15 g. in 125 cc. of 2 *N* NaOH shaken about 20 min. with 18 g. MeI at 65-8° until completely dissolved, kept 20 min. more at the same temp., cooled and pptd. with HCl, is obtained 13 g. of the *N*-methyl derivative, needles or thick prisms from 70 parts H₂O, sinters about 117°, m. 121.5-2.5°, $[\alpha]_D^{20}$ -6.67°, hydrolyzed by HCl (d. 1.19) after 8 hrs. at 100° to *d*-*N*-methylalanine hydrochloride, needles from

alc.-Et₂O, sinters 158°, m. 165.5–6.0°, $[\alpha]_D^{20}$ 5.74° in H₂O, very hygroscopic, deliquesces in the air, gives no ppt. with KI.BiI₃, converted by boiling with PbO into the free *alanine*, needles with 1 H₂O from alc. (yield, more than 75%), m. about 300° (partial decompn.) when heated rapidly, partially subliming, tastes somewhat sweet. *Copper salt*, blue rhombic tables with 2 H₂O. *p-Toluenesulfo-l-leucine* (a), obtained in 50 g. yield from 30 g. formyl-*l*-leucine boiled 1.5 hrs. in 10 parts of 10% HCl, concd. to crystn. under 15–20 mm., taken up in a little H₂O, evapd. to dryness, dissolved in 75 cc. H₂O, neutralized with *N* NaOH, treated with more NaOH (about 450 cc. in all) until just dissolved, then with 72 g. MeC₆H₄SO₃Cl in 375 cc. Et₂O and shaken 4 hrs. with 279 cc. of 2 *N* NaOH added in 3 portions, sepd. from the Et₂O, satd. with 5 *N* HCl and crystd. from 1400 cc. of 20% alc., needles or prisms, m. 124°, $[\alpha]_D^{18}$ 4.40° in alc. *N-Methyl derivative* (b), obtained in 30 g. yield from 28.5 g. of (a), 6-sided tables from CS₂-petr. ether, m. 91–2°, $[\alpha]_D^{18}$ –21.09° in alc.; *ammonium salt*, needles from alc.-Et₂O, m. about 136°. *l-N-Methylleucine*, obtained in 64% yield after 15 hrs. heating of (b) with 10 parts of HCl (d. 1.19) at 100° or after 10–15 min. at 85–90° with 1 part PH₄I and 15 parts HI (d. 1.96), cryst. ppt. from H₂O-acetone, sublimes in needles on cautious heating with only slight decomp., $[\alpha]_D^{19}$ 20.44° in H₂O, sol. in 22.45 parts H₂O at 25°, tastes faintly bitter; its aq. soln. acidified with H₂SO₄ gives with phosphotungstic acid, even at relatively large dilns., a resinous ppt. quite easily sol. on warming; the satd. aq. soln. is pptd. by satd. (NH₄)₂SO₄; with a little concd. HNO₃ is obtained a *nitrate*, needles or prisms from alc.-Et₂O. *Hydrochloride*, needles, $[\alpha]_D^{19}$ 21.29° in H₂O. *Copper salt*, elongated 4- or 6-sided plates with 1 H₂O. *p-Toluenesulfonyl-d-phenylalanine*, obtained almost quant. from formyl-*d*-phenylalanine, hair-like needles from alc., m. 164–5°, $[\alpha]_D^{19}$ 2.42° in acetone, is *l*-rotatory in CHCl₃. *Sodium salt* seps. with 3.5 mols. H₂O. *N-Methyl derivative* (c), rectangular tablets with C₆H₆ of crystn. from C₆H₆-petr. ether, m. (solvent-free) 92–3°, $[\alpha]_D^{20}$ 32.63° in acetone; it is obtained pure through the *sodium salt*, needles with 2 H₂O, hygroscopic when dehydrated. *d-N-Methylphenylalanine hydrochloride*, obtained in 91% yield from (c) heated 16 hrs. with HCl at 100°, rectangular tablets from alc.-Et₂O, easily loses HCl, *l*-rotatory in H₂O, the rotation increasing on addition of HCl. Free *alanine*, from the HCl salt in alc. neutralized to litmus with 10% aq. LiOH, felted needles from 40 parts boiling H₂O, becomes strongly electrified on rubbing, sublimes partially undecompd., tastes sweetish bitter, easily sol. in dil. acids and alkalies, gives in faintly ammoniacal soln. with AgNO₃ on boiling a cryst. ppt. sol. in HNO₃, forms in acid soln. with phosphotungstic acid a resinous ppt. quite sol. on heating and in excess of the phosphotungstic acid, $[\alpha]_D^{18}$ –48.22° in 0.1 *N* NaOH, –17.7° in *N* HCl at 20°. *p-Toluenesulfonyl-l-phenylalanine*, m. 164–5°, $[\alpha]_D^{21}$ –2.11° in acetone; *sodium salt*, seps. with 3.5 H₂O. *N-Methyl derivative*, m. 92.5–4.0°, $[\alpha]_D^{19}$ –32.06° in acetone; *sodium salt*, seps. with 2 H₂O. *l-N-Methylphenylalanine*, $[\alpha]_D^{19}$ 49.06° in 0.1 *N* NaOH. *Ethyl N-p-toluenesulfonyl-l-tyrosine*, obtained in 65 g. yield from 60 g. HOC₆H₄CH₂CH(NH₂)CO₂Et.HCl, 12 g. soda and 60 cc. H₂O shaken with 360 cc. CHCl₃ and then with 47 g. MeC₆H₄SO₃Cl in 150 cc. CHCl₃, allowed to stand some hrs., again shaken 2 hrs. with 12 g. more soda in 60 cc. H₂O and the CHCl₃ layer dried with Na₂SO₄, concd., seeded and pptd. with petr. ether, needles, m. 114°, $[\alpha]_D^{17}$ 6.76° in alc., gives the Millon reaction, hydrolyzed by 5 *N* NaOH after 20 min. on the H₂O bath to *N-p-toluenesulfonyl-l-tyrosine* (yield, 40 g. from 45 g. ester), needles or prisms from 30% alc., m. 187–8°, $[\alpha]_D^{21}$ –0.85° in alc. $[\alpha]_D^{20}$ –8.58° in 0.5 *N* NaOH, easily sol. in excess of alkali, while the monoalkali and ammonium salts are relatively but little sol. in cold H₂O. Heated 75 min. at 70° with 3 mols. MeI in 3 mols. of 0.5 *N* NaOH, it gives almost quant. *N-p-toluenesulfonyl-O,N-dimethyl-l-tyrosine*, quadrangular plates from dil. alc., m. 141–2°, $[\alpha]_D^{20}$ –26.75° in alc., behaves towards Millon's reagent like *O,N*-dimethyltyrosine (Friedmann and

Gutmann, C. A. 5, 482); 5 g. heated 15 min. in a H_2O bath with 25 cc. HI (d. 1.96) and 3.5 g. PH_4I , gives $p\text{-MeC}_6\text{H}_4\text{SH}$ and 2.4 g. of $l\text{-N-methyltyrosine}$, $[\alpha]_D^{19}$ 19.75° in 11% HCl, identical with natural ratanhine (Goldschmiedt, C. A. 7, 589; by mistake, he reports it as being l -rotatory). The Me ester m. 111–2° (G., 116–7°). C. A. R.

Diacylamides. OTTO MUMM, HUGO HESSE AND HANS VOLQUARTZ. Univ. Kiel. Ber. 48, 379–91 (1915); cf. C. A. 4, 1750.—While many alkyl derivs. of acid amides are known in the 2 isomeric forms $RCONHR'$ and $RC(:NH)OR'$, thus far (with 1 possible exception; cf. Kuhara, C. A. 5, 1278) the corresponding acyl compds. have been obtained in only 1 form, to which has generally been assigned the amide structure, $RCONHCOR'$. In the prepn. of diacylamides by shaking an imide chloride in Et_2O or ligroin with the Na salt of an acid in H_2O , the O -acyl compd. is probably an intermediate product and rearranges into the N -acyl isomer: $RCCl:NR' + NaO_2CR'' \longrightarrow RC(O_2CR''):NR' \longrightarrow RCONR'COR''$, and attempts have now been made in various ways to isolate 2 such isomeric forms. To show whether intramol. rearrangement is possible under the conditions of the expt. $PhCCl:NPh$ was treated with $m\text{-O}_2NC_6H_4CO_2Na$ on the 1 hand, and $m\text{-O}_2NC_6H_4Cl:NPh$ with $BzONa$ on the other; if there were no rearrangement the products should be different, but as a matter of fact they were identical, $O_2NC_6H_4CONPhBz$. A residue of high mol. wt. was next chosen as the entering acyl; $PhCCl:NPh$ and Ph_3CCO_2Na gave *triphenylacetylbenzanilide*, microscopic needles from C_6H_6 , m. 185–6°, which again was identical with the product from $BzONa$ and *triphenylacetanilide imide chloride*, prismatic columns from ligroin, m. 137°; this chloride was obtained by warming with PCl_5 *triphenylacetanilide*, m. 167–8°, which, in turn, was prepd. from Ph_3CCOCl and $PhNH_2$. Similarly, $PhCCl:NPh$ with mono-Na malonate gave *malonylmonobenzanilide*, prisms from C_6H_6 , m. 100–1° (gas evolution); with $(CH_3CO_2Na)_2$, *succinyldibenzanilide*, prisms from $MeOH$, m. 146–7°; with Na fumarate, *fumaryldibenzanilide*, m. 194° (decompn.). It was thought that if the entering (aromatic) acyl or the imide chloride were substituted in the o -position, the rearrangement of the O - into the N -acyl compd. might be prevented, but again no isomeric forms could be detected. $PhCCl:NPh$ and $o\text{-MeC}_6\text{H}_4CO_2Na$ gave *o-toluybenzanilide*, m. 134–5°; $o\text{-MeC}_6\text{H}_4N:CPhCl$ and $NaOBz$ yielded *dibenzoyl-o-toluidide*, prisms from alc., m. 111–2°; *dibenzoyl-o-nitroanilide*, 4-sided tables from alc., was obtained from $O_2NC_6H_4N:CPhCl$ and $NaOBz$. *Dibenzoyl-m-toluidide*, needles from alc., m. 140–1°; *p-toluidide*, prisms from alc., m. 142–4°; *m-nitroanilide*, prisms from alc., m. 150–1°; *methylamide*, $MeNBz$, prismatic columns from alc., m. 94–5°; *benzylamide*, prisms from alc., m. 108°, were similarly obtained from $BzONa$. Thinking the strength of the acid whose radical enters might influence the stability of the O -acyl compd., salts of acids of the most varied strength and of various phenols were tried but again, except in the case of $PhOH$ itself, no isomers were obtained. $PhCCl:NCH_2Ph$ and $PhCH:CHCO_2Na$ gave *cinnamoylbenzoylbenzylamide*, prisms from alc., m. 113°. $PhCCl:NPh$ and $PhONa$ give $PhC(OPh):NPh$ (Hantzsch, Ber. 26, 926 (1893)), m. 105°, which, when heated 1 hr. at 240° and crystd. from alc., rearranges into $BzNPh_2$, m. 180°, obtained from $BzCl$ and $NHPh_2$ (Hofmann, Ann. 132, 166 (1865)). *Benzanilide-o-nitrophenyl ether*, from $PhCCl:NPh$ and $O_2NC_6H_4ONa$, cubes from alc., m. 116°, could not be converted into an isomer. *Benzpicrylanilide*, long needles from alc., m. 195–6°; *benzpicryl-o-toluidide*, light yellow rhombs from alc., m. 223–4°; [*o*-hydroxybenzoyl] *benzanilide*, prisms from C_6H_6 , m. 189°; [*o*-hydroxybenzoyl] *bens-o-toluidide*, needles from alc. or C_6H_6 , m. 122–3°. Treatment of $PhCCl:NPh$ in the presence of C_6H_5N with acids in abs. Et_2O (Claisen, Ann. 291, 106 (1896)) gave products identical with those obtained as above from the salts. The above syntheses do not permit of deciding whether in the diacylamides both acyl groups are really attached to the N or whether the compds. are not perhaps at

least partially *O*-acylated derivs. It was now attempted to clear this up by so choosing the acid residues that here would be a possibility of intramol. ring formation; from the structure of the resulting cyclic compd. it should then be possible to deduce that of the diacylamide. PhCCl:NPh and $o\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Na}$ give diphenylquinazolone (*C. A.* 4, 3233), so that the $\text{H}_2\text{NC}_6\text{H}_4\text{CO}$ residue must be attached to the N; on the other hand, the 3 isomeric $\text{O}_2\text{NC}_6\text{H}_4\text{N:CPhCl}$ and $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{Na}$ yield benzoylanthranil, so that the $\text{H}_2\text{NC}_6\text{H}_4\text{CO}$ must be attached to the O. With $\text{MeNHC}_6\text{H}_4\text{CO}_2\text{Na}$ is obtained [*o*-methylaminobenzoyl]benzanilide, prisms from AcOEt , m. 188° , which when boiled several hrs. with dil. HCl changes into an (apparently cyclic) isomer, $\text{NMe.C}_6\text{H}_4\text{CO.NPh.CPhOH}$, m. 142° . In some

cases, the decompn. of the diacylamides at room or elevated temp. may also throw light on their structure. Thus, *oxalylidibenzanilide*, from PhCCl:NPh and $(\text{CO}_2\text{K})_2$ prisms from alc., m. $212\text{--}3^\circ$ (gas evolution), when heated 1 hr. at $220\text{--}30^\circ$, gives 1 mol. each of CO , CO_2 and BzNPhCPh:NPh , showing that at least 1 side of it is acylated on the O. *Oxalylidibenz-o-toluidide*, m. $171\text{--}3^\circ$. When $(\text{CO}_2\text{K})_2$ reacts on $p\text{-O}_2\text{NC}_6\text{H}_4\text{N:CPhCl}$, not only does the *O*-acyl at once rearrange into the *N*-acyl compd. but the *Bz* is also replaced by a HO_2CCO group and the product obtained is *dioxalyl-p-nitrobenzanilide*, $\text{O}_2\text{NC}_6\text{H}_4\text{N(COCO}_2\text{H)}_2$, needles from AcOH , m. 270° (decompn.), converted by dil. HCl into $\text{O}_2\text{NC}_6\text{H}_4\text{NHCOCO}_2\text{H}$. $\text{HO}_2\text{CCO}_2\text{Na}$ and PhCCl:NPh likewise yield an *O*-acyl compd. which, however, spontaneously loses 1 mol. each of CO and CO_2 and forms BzNHPh . The great tendency of the *O*- to rearrange into the *N*-acyl derivs. is probably conditioned by partial valences on the migrating C and the N atom. That the compds. sometimes react like *O*-acyl derivs. is probably due to the fact that they exist in a tautomeric equil. of the 2 forms.

CHAS. A. ROULLER.

The use of aqueous mercuric acetate solution for the investigation of the terpene-constituents of ethereal oils. L. BALBIANO. Turin. *Ber.* 48, 394-400(1915).—By means of satd. $\text{Hg}(\text{OAc})_2$ paraffins, aromatic hydrocarbons, cycloparaffins, olefins and terpenes can be detected and detd. in mixts. of hydrocarbons. Purest pinene, prepd. by Wallach's method from the nitroso chloride (*Ann.* 258, 344(1890)), when boiled 2-4 hrs. under a reflux condenser with the required amt. of $\text{Hg}(\text{OAc})_2$ in 4 parts. of H_2O , is completely decompd.; a large part resinifies but about 50% is converted into dihydroxypinene (isolated as the semicarbazone); no appreciable amt. of cymene is formed. Petr. ether and pinane are not attacked and a large part is recovered when mixts. with pinene are treated as above with $\text{Hg}(\text{OAc})_2$. Camphene boiled 2 hrs. with aq. $\text{Hg}(\text{OAc})_2$ in the presence of AcOH gives a ppt. of the compd. $\text{C}_{10}\text{H}_{16}\text{O}(\text{HgOAc})_2$ (a) which regenerates camphene with Zn and HCl on the H_2O bath; if C_6H_6 or pinane are also present, they are largely recovered unchanged. The following is an example of a mixt. analyzed by this method: 5 cc. pinene, 2 cc. cymene, 2 cc. pinane and 1 g. camphene are boiled 2.5 hrs. with 33 g. $\text{Hg}(\text{OAc})_2$ in 132 cc. H_2O ; from the steam distillate of the reaction mixt. there seps. 3.5 cc. of an oily mixt. of cymene and pinane which no longer reacts with $\text{Hg}(\text{OAc})_2$, showing that the reaction is complete. From the ppt. of HgOAc and (a) there is obtained, by treatment with Zn and HCl and subsequent steam distn., about 0.6 g. camphene. The aq. soln. is concd. on the H_2O bath, the residue dissolved in Et_2O , the soln. washed with H_2O and concd.; there remains a red-yellow oil which with $\text{H}_2\text{NCONHNH}_2\cdot\text{HCl}$ and KOAc in alc. gives 0.8 g. of dihydroxypinene semicarbazone.

CHAS. A. ROULLER.

Polymerizations in tri- and tetra-alkylated pyrroles. HANS FISCHER. Univ. Munich. *Ber.* 48, 401-6(1915).—*Biskryptopyrrole* (I) is obtained as the HCl salt when kryptopyrrole (a) in Et_2O is treated with dry HCl . When 4 g. (a) picrate in 40 cc. AcOEt is boiled 2 hrs. or allowed to stand 15 hrs. at 48° and cooled in ice, 2 g.

unchanged (a) picrate seps. in about 2 hrs.; the mother liquors, treated with petr. ether and rubbed, yield in 4-5 hrs. orange-red crystals which, when treated with CHCl_3 , leave a small residue (0.02 g.) of a yellow picrate m. above 290° which does not give the Ehrlich aldehyde reaction. The CHCl_3 soln., treated with Et_2O , yields 0.5 g. of the orange *picrate* of (I), m. $154-5^\circ$ (cor.), gives a negative Ehrlich reaction; with NaOH

this yields the free (I) as an oil which does not depolymerize up to 170° *in vacuo* but above 200° the oil which distills over gives the picrate of (a). Phyllopyrrole (b) is polymerized even more easily; when its picrate is boiled only 0.5 hr. with AcOEt , on cooling there crysts. a product, m. $103-4^\circ$ (cor.), having approx. the comp. of Piloty's hemopyrrole g (C 51.59, H 5.74, N 14.70%); complete polymerization is effected by boiling 6.1 g. (b) and 11 g. picric acid in 170 cc. AcOEt for 2 hrs.; on treating with petr. ether to incipient turbidity, freeing the crystals of tar by rubbing with AcOEt or alc. and crystg. from alc. or CHCl_3 and petr. ether, there is obtained 5.3 g. of the light yellow *picrate*, m. 147.5° , of *bisphyllopyrrole* (II), which is non-cryst. and is not or only very slightly volatile with steam, being partially depolymerized by the steam, for the distillate contains a small amt. of (b); by distn. *in vacuo* at about 150° , about 50% of (b) is recovered from (II). That the polymerization does not occur at room temp. was shown in a special expt. Piloty's hemopyrrole e is polymerized (a), probably formed by long boiling with AcOEt in the sepn. of the pyrrole picrates; it is not originally present in the pyrrole mixt. F. in his work pours the boiling solvent on the pyrrole picrates, boils a few sec. at most, quickly filters and at once cools with ice. Hemopyrrole g is essentially (b) contaminated with the bis compd., and hemopyrrole f is doubtless a similar bis compd. Contrary to P.'s experience (C. A. 9, 57), F. again finds that phyllopyrrolecarboxylic acid is easily obtained from the phono acid and NaOMe (KOME is better) heated 3 hrs. at 225° (cf. C. A. 7, 1495). It is similarly obtained from the isophono acid (C. A. 8, 1770).

CHAS. A. ROULLER.

Synthesis of high molecular derivatives of papaverine. MARTIN FREUND AND KARL FLEISCHER. Univ. Frankfurt a/M. Ber. 48, 406-9 (1915).—Like narcotine and hydrocotarnine (C. A. 6, 2600-1), papaverine (a) contains a free H atom in the 5-position of the isoquinoline residue and like them it condenses with opianic acid (b) and HCHO . *Opian(lact)ylpapaverine*, $\text{C}_{40}\text{H}_{49}\text{O}_8\text{N}_2$, obtained in 46 g. yield from 33.9 g. (a) and 21.0 g. (b) allowed to stand 3 days in 120 cc. H_2SO_4 (90 g. of 96% acid: 10 g. H_2O), poured into cold H_2O , satd. with dil. NH_3 , filtered and warmed moderately with alc., microscopic needles from alc.- CHCl_3 , m. $168-70^\circ$, sol. in concd. H_2SO_4 , without color but turning a bright violet on the addition of a trace of dil. acid. *Hydrochloride*, thick felted needles with 1 H_2O , decomp. 167° . *Methylenedipapaverine* $\text{C}_{44}\text{H}_{49}\text{O}_8\text{N}_2$, obtained in 20 g. yield from 33.9 g. (a) and 25 cc. of 35% aq. HCHO allowed to stand 4 days with 80 cc. of H_2SO_4 (80 g. of 96% acid: 20 g. H_2O), filtered, dissolved in hot H_2O , pptd. hot with 10% NH_3 , filtered and warmed with alc., m. $204-6^\circ$, sol. without color in concd. H_2SO_4 and turning intensely blue on addition of a trace of dil. HNO_3 . *Dihydrochloride*, seps. with 2 H_2O .

A. GENERAL.

FRANK P. UNDERHILL.

Sensitiveness of the peroxidase reaction. A. BACH. *Genf. Ber.* 47, 2122-4 (1914).—The sensitivity of a very pure prep. of peroxidase made by pptn. with EtOH and subsequent filtration of the aq. soln. on a special filter so as to hold back only the colloidal ferment, was found to be of the order of 1 to 500 million when allowed to react with guaiacol and H_2O_2 for five min. Increasing the reaction time to 20 min. and 24 hrs. increased the sensitiveness to 1 to 1 billion and 1 to 2 billion, resp. E. M. F.

Notes on the mechanism of biological oxidation processes. OSCAR LOEW. *Ber.* 47, 2462-4 (1914).—L. regards the oxidative processes of the body as taking place not as a result of activated O, but rather by means of "labilized" H atoms of the proteins of the cells so that they react readily with mol. O_2 . The H_2O_2 formed in the reaction is at once removed by the catalase always present. This process he terms induced oxidation. E. M. FRANKEL.

Electric charge of the protoplasm and other substances in living cells. J. F. McCLENDON. Minneapolis. *Intern. Z. physik. chem. Biol.* 1, 159-62 (1914).—The anthocyan in vacuoles of living cells of red cabbage is red and cathodic (electrically positive). If alkali be added to the medium the anthocyan becomes blue and anodic before the death of the cell. It appears therefore to be an amphoteric electrolyte like egg albumen. E. M. FRANKEL.

Absorption of water through skin of the frog. J. F. McCLENDON. Minneapolis. *Intern. Z. physik. chem. Biol.* 1, 169-72 (1914).—Absorption of H_2O by a frog leg in which the circulation has stopped is the result of the osmotic pressure of the fluids in and between the cells of the tissues. E. M. FRANKEL.

Abderhalden's protective enzymes. C. BRAHM. Berlin. *Z. angew. Chem.* 27, I, 464-6 (1914).—Outline of theory and methods used. E. M. FRANKEL.

Optical rotation, adsorption and centrifugalization of pepsin solutions. M. RAKUZIN. *J. Russ. Phys. Chem. Soc.* 47, 141-3 (1915).—The rotation of pepsin in H_2O is $[\alpha]_D +64.5^\circ$. When an aq. soln. of pepsin is shaken with 10% by wt. of soln. of Al_2O_3 for 1 hr. there is a drop in the rotation and in the sp. gr., showing positive adsorption, while if the pepsin soln. be boiled for a few min. with 3% of gelatin the rotation drops to 0° (gelatin being levorotatory), but the sp. gr. increases, showing negative adsorption. An attempt to cause a sepn. of pepsin by centrifugalizing its soln. failed. H. M. GORDIN.

Optical and other properties of albumins. I. Rotation, adsorption and centrifugalization of egg albumen. M. A. RAKUZIN. *J. Russ. Phys. Chem. Soc.* 47, 144-7 (1915).—The rotation of egg albumen is $[\alpha]_D -39.73^\circ$, showing that the 2 modifications of albumin (Panormov, *J. Russ. Phys. Chem. Soc.* 1898, 302) are in the egg in unequal proportions. When a 50% soln. of egg albumen is digested for 24 hrs. *in vacuo* with 10% by wt. of soln. of Al_2O_3 the rotation decreases, showing positive adsorption, while if the albumen soln. is warmed for 15 min. to $40-50^\circ$ with 1% of gelatin the *l*-rotation and the sp. gr. increase, showing negative adsorption (gelatin being levorotatory). **II. Rotation, adsorption and centrifugalization of casein solutions.** *Ibid* 147-9.—A soln. of casein in H_3PO_4 (1:12) or in AcOH has $[\alpha]_D -86.6^\circ$, while in a 2% soln. of borax or in $H_2O + 0.2\%$ pepsin + 2% HCl $[\alpha]_D -95.3$ to 95.4° . When a soln. of casein containing 2% of borax is shaken with 10% by wt. of soln. of Al_2O_3 for 1 hr. the sp. gr. and the rotation decrease, showing positive adsorption. The latter is still

greater if the mixt. be digested for 24 hrs. Centrifugalization of a borax-containing soln. of casein caused a sepn. of but an insignificant amt. of it. H. M. GORDIN.

Spectroscopic investigation of the reduction of hemoglobin by tissue reductase. D. F. HARRIS AND H. J. M. CREIGHTON. Dalhousie Univ. and Swarthmore College. *J. Biol. Chem.* 20, 179-201 (1915).—Reductase was obtained from the liver of the cat, rabbit, pigeon, frog and mackerel, from cat and pigeon muscle juice, from the heart of the cat and rabbit and from the kidney, stomach and cortex cerebri of the cat. Its reducing action on oxyhemoglobin at 40° was studied spectroscopically. The liver juice of all the animals had the greatest reducing power, that of the pigeon reducing the oxyhemoglobin to the one-banded condition instantly at room temp. The muscle juice of the cat showed only slight reducing action while that of the pigeon brought about reduction in 2 mins. The juices of the other organs showed varying degrees of activity. Sol. Prussian blue was also reduced to the leuco base by the juices studied. The reductase is not specific as the reductase of any one animal reduces the blood of any other. The rate of reduction increases with the temp., being most rapid between 10 and 40° and decreasing rapidly above 40° and below 10°. Below 0° inhibition is complete but the juice regains its activity on raising the temp. The activity of the cat liver juice decreases with age and practically disappears after 8 days. A logarithmic curve is obtained by plotting the reducing power against the age of the juice. The decay in the activity of reductase follows the unimolecular law. The expts. show the presence in the tissues of mammals, birds, amphibia and fishes of an intracellular enzyme having energetic reducing powers. The authors believe "that reductase is the chief factor in causing dissociation of O from oxyhemoglobin in the tissues" and that internal respiration is *originated by reductase*, which removes O from the oxyhemoglobin and from the lymph in a nascent condition, in which it is applied to the oxidizable substances in the cell through the activity of an oxidase. ALFRED P. LOTHROP.

Glucolysis. IV. Catalytic influence of oxidative glucolysis. WILHELM BEYSEL AND WALTHER LÖB. Berlin. *Biochem. Z.* 68, 368-401 (1915); cf. *C. A.* 7, 492.—The oxidation of glucose, HCHO and glycolaldehyde is accelerated by PO₄; thus there is a catalysis of the action of the HO-ion by the PO₄-ion which cannot be produced by the glycoll or boric acid ion, even if the solns. used have the same or larger HO-ion concn. than the PO₄-soln. The accelerating action of the PO₄ increases with the amt. of PO₄ added; the H-ion exponent, p_H 7.4-7.5, which is about that of blood alkalescence, is the most suitable for the PO₄ ion glucolysis. Slight amts. of glycoll produce a direct retardation of the oxidation by H₂O₂, an effect not shown by boric acid salts. In the oxidative PO₄ glucolysis of grape sugar in blood alkalescence there is formed besides hydroxy acids, HCO₂H and CO₂ from the decompn. of pentoses and HCHO. HCHO and glycolaldehyde behave towards PO₄, borates and glycoll, when oxidized by H₂O₂, essentially the same as grape sugar. C. J. WEST.

Chemistry of the proteolytic enzymes. E. HERZFELD. Univ. Zürich. *Biochem. Z.* 68, 402-35 (1915); cf. *C. A.* 8, 3560.—The active enzyme preps., upon dialysis, give more compds. reacting with ninhydrin and split off from the same proteins more such compds., than less active compds. In the dialysis of pepsin, the dialysate always gives the biuret reaction (comparable with the peptones), while trypsin dialysate gives a negative biuret (comparable with the amino acids). The decrease of such dialyzable compds. in acid or alk. solns. is also seen in their action upon protein compds., where a correspondingly smaller amt. of the dialyzable substs. results. These facts lead to the conclusion that dialyzable protein decompn. products, peptones and amino acids, may participate in the catalysis of protein hydrolysis. This conclusion was confirmed in a series of expts. in which it was shown that peptones accelerate proteolytic processes. There seems to be a certain specificity, in that peptone from

albumin catalyzes the hydrolysis of albumin more than that of fibrin, while it has no effect upon that of casein and edestin. In the same way, a synthetic peptide, leucylglycine, exerts a catalytic action. In the hydrolysis of such a peptide the amino acids have a strong catalytic action. This is also seen in the hydrolysis of proteins, glycooll, leucine, glutaminic acid and alanine accelerating the reaction strongly, phenylalanine slightly, while asparagine and tryptophan had no effect. A mixt. of amino acids has the same effect. The amt. of decompn. is less in the presence of 0.5% Na_2CO_3 . In expts. which ran for 1000 hrs., the last period was characterized by a decrease (synthesis?) of the decompn. products. Certain expts. are reported showing that an active trypsin prepn. does not lose all its activity when heated; glycooll in 0.5% Na_2CO_3 shows a similar behavior.

C. J. WEST.

Peptone. II. ALESSANDRO BERNARDI AND EMMA FABRIS. Univ. Bologna. *Biochem. Z.* 68, 436-40(1915); cf. C. A. 8, 1796.—The insol. portion obtained by treating the aq. soln. of Witte peptone with $\text{Cu}(\text{OH})_2$ is washed free of Cu with hot H_2O , dissolved in hot NH_4OH and the blue soln. satd. with H_2S . The filtrate is evapd. to dryness, extd. with H_2O and satd. with NaCl , MgSO_4 or best with AcONa . When a conc. of 21% NaOAc is reached a yellow subst. ppts. which is only partly sol. in H_2O . Extd. with H_2O , concd. to a thick sirup and poured into abs. alc., there ppts. a brownish yellow substance, $\text{C}_{47}\text{H}_{137}\text{N}_{19}\text{O}_{37}\text{S}_2$, rather sol. in H_2O , pptd. by phosphotungstic acid, but not by FeCl_3 , MgSO_4 or AcOH . It gives a negative biuret reaction, positive Millon and xanthoproteic reactions and becomes turbid upon adding AcOH . The mother liquor from the AcONa ppt. is concd. and poured into alc., giving a compound, $\text{C}_{44}\text{H}_{124}\text{N}_{11}\text{O}_{24}\text{S}$, which is sol. in cold H_2O , has a very weak alk. reaction, is pptd. by picric and phosphotungstic acids; the ppt. with AcOH , ZnSO_4 or HCl is sol. in excess of the reagent. It gives a positive biuret, Millon and xanthoproteic reaction.

III. *Ibid* 441-3.—A 10% aq. soln. of the earlier described compd. $\text{C}_{44}\text{H}_{124}\text{N}_{11}\text{O}_{24}\text{S}$ is satd. with dry HCl at 0° , the dark violet soln. concd. on the H_2O bath, extd. with Et_2O and the residue extd. with AcMe . The AcMe ext. is concd. to dryness, the residue extd. with H_2O , the ext. treated with $\text{Cu}(\text{OH})_2$, the clear blue soln. concd. and poured into AcMe . This gives a compound, $\text{C}_{14}\text{H}_{32}\text{N}_4\text{O}_{10}\text{Cu}_2$, forming blue needles which begin to decomp. at 200° , m. 211° (decomp.). It is sol. in hot H_2O .

C. J. WEST.

Behavior of cane sugar under the influence of the silent discharge. WALTHER LÖB. Berlin. *Biochem. Z.* 69, 36-8(1915).—Cane sugar is hydrolyzed by the silent discharge. Fifty cc. 2.5% sugar soln., containing 48.2 mg. and 57.2 mg. reducing sugar, contained 110 mg. and 302.4 mg. after the action of the silent discharge for 12 hrs. In a 30 hr. expt., acid formed corresponding to 0.35 cc. 0.1 N NaOH . A secondary decompn. by H_2O_2 was prevented by carrying the action out in a vacuum of 20 mm.

C. J. WEST.

Electroculture. I. Influence of the silent discharge upon enzyme reactions. WALTHER LÖB AND A. SATO. Berlin. *Biochem. Z.* 69, 1-35(1915).—Aq. solns. of starch are hydrolyzed by the action of the silent discharge both in the presence and absence of O. The part of the starch not hydrolyzed in this process is changed, perhaps in the sense of a polymerization, perhaps otherwise, so that it is more stable towards diastase than the untreated starch. The elec. treatment of pancreatin solns. retards considerably the diastatic properties of the same. In the same way the reaction between diastase and starch is retarded. Silk peptone solns. are hydrolyzed only to a very slight degree, giving free NH_3 . Amino acids and non-colloidal N substances are present only in traces. Casein and fibrin are stable. The tryptic properties of pancreatin solns. are retarded by the discharge. The reaction between enzymes and casein is slightly retarded. Tributyrin is hydrolyzed by the action of the silent discharge. The lipase of the pancreatin is weakened by the discharge.

C. J. WEST.

Activation of soy urease by human serum. RUDOLF NEUMANN. Berlin. *Biochem. Z.* 69, 134-40(1915).—Human serum increases the urea-splitting activity of soy urease about 8 times. A quant. difference in this auxoureatic action could not be established for sera of different diseases, the amt. being fairly const. in all cases. Fluid from a pleural puncture had the same effect as serum. That from lumbar puncture is not as active, the greatest activity being found in a case of tubercular meningitis.

C. J. WEST.

The (serologically demonstrable) protein of honey is the same as that of the bee (Langer) and not of the pollen (Küstenmacher). JOSEPH LANGER. Graz. *Biochem. Z.* 69, 141-4(1915).—L. restates his views (*C. A.* 3, 2716; 4, 332) as opposed to the conclusions of K. (*C. A.* 5, 2488).

C. J. WEST.

Recent work on vitamines. H. L. WATSON-WEMYSS. *Edinburgh Med. J.* 14, 186-93; *J. Comp. Path. Therap.* 28, 53-9(1915).—A review.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Identification of traces of bilirubin in albuminous fluids. A. A. HYMAN VAN DEN BERGH AND J. J. DE LA FONTAINE SCHLUTTER. *Proc. K. Akad. Wetenschappen* 17, 807-10(1914); *J. Chem. Soc.* 108, II, 116.—To detect with certainty the presence of small quantities of bilirubin in blood serum or other albuminous fluid, 20 cc. of pure acetone are added to 10 cc. of the serum, and the more or less intensely yellow soln., after removal of the albumin ppt., is evapd. in a vacuum at the ordinary temp. until the acetone has been removed. The residual aq. soln. is treated with ether to remove the fatty substances, 2 cc. of CHCl_3 are added, and the mixt. is faintly acidified with HCl and well shaken. The CHCl_3 soln. contg. the bilirubin is thoroughly washed with water to remove all the HCl, and is dried, if necessary, with anhydrous Na_2SO_4 . Bilirubin can be detected in the yellow CHCl_3 soln. by the usual tests, by the reactions of Gmelin and of Ehrlich, and by the isolation of yellow, microscopic crystals. The following remarkable observation has been made during the exam. of the serum of 2 patients suffering from obstructive jaundice, and only in these 2 cases. After the blood serum had been treated by the preceding method, the final CHCl_3 soln. was allowed to evap. slowly at 0° ; when the concn. had reached a certain value the yellow color of the soln. changed suddenly to green, evidently owing to a change of bilirubin to biliverdin.

E. J. C.

Determination of urea. A. DESGREZ AND R. MOOG. *Compt. rend.* 159, 250-3 (1914).—The urea is decompd. in the presence of infusorial earth as a catalyzer with a soln. prepd. by dissolving 50 g. Hg in 100 g. 36°Bé . HNO_3 , and the liberated gas after absorption of the CO_2 measured over CHCl_3 . Allantoin reacts in the same way. A new form of ureometer is described for use with this method.

E. M. FRANKEL.

Quantitative gravimetric determination of small amounts of urea in dilution greater than 1 : 1000. R. FOSSE. *Compt. rend.* 159, 253-6(1914).—The method of F. (cf. *C. A.* 8, 3450) is shown to be applicable to solns. of urea containing 0.01-0.1%, 0.01 g. being estd. with an accuracy greater than 1%.

E. M. FRANKEL.

Determination of protein ammonia. L. W. WINKLER. Budapest. *Z. angew. Chem.* 27, I, 440(1914).—100 cc. of H_2O are treated with 1-2 drops of conc. H_2SO_4 , and approx. 0.05 g. powdered $\text{K}_2\text{S}_2\text{O}_8$ and boiled on the steam bath for 15 min., cooled to room temp. and treated with 5 cc. of a reagent contg. equal parts of Nessler and Na K tartrate solns. Enough NH_4Cl soln. (1 cc. = 0.1 mg. NH_3) is added to make the color of the soln. the same as the color developed by mixing the same quantity of H_2O with the same reagents (the boiling being omitted). The amt. of NH_3 added is

equal to the protein NH_3 . Care must be taken to recryst. the $\text{K}_2\text{S}_2\text{O}_8$, as the reagent may contain $(\text{NH}_4)_2\text{S}_2\text{O}_8$ (cf. *C. A.* 7, 2175). E. M. FRANKEL.

Toxic products in food and their detection. CHAS. H. HIGGINS. *Centr. Bakt. Parasitenk., Abt. I* 74, 193-7(1914).—In testing the presence of toxic substances in food, usually gelatin, a soln. of the sample is made in *N* NaCl soln. or distd. H_2O which is heated to 60° during 1 hr. Gradually increasing doses (from 1 to 10 cc.) of this soln. are injected subcutaneously into guinea pigs. If no symptoms or deaths occur within 5 days, the food is passed as being suitable for human food. If they do occur, further tests are made to det. whether bacteria or sol. toxins are present. J. H. LEWIS.

Methods of measuring and researches with tryptoprotease. F. M. MARRAS. *Centr. Bakt. Parasitenk., Abt. I* 74, 505-15(1915).—All the methods that have been suggested for measuring proteases that act in an alk. medium are reviewed and criticized. M. compared the serum plate method of Jochmann-Müller, the casein tube method of Fuld-Gross, and the gelatin plate method of Ferns. In his opinion the gelatin plate method, besides being certain and simple, requires a shorter time and a lower temp. for reaction. JULIAN H. LEWIS.

Experiences with the phenolsulfonephthalein method of testing the function of the kidney. OTTO HESS. Cologne Academy. *Bull. Johns Hopkins Hosp.* 26, 52-4(1915).—A report is made of the results of 300 tests of kidney function using the phenolsulfonephthalein method. The test is superior to other color tests. It shows how much of the parenchyma is involved and is of much value in the differential diagnosis of doubtful renal tumors. It can be applied immediately without any dietary prep. and can be used even in uremic conditions. There is a parallelism between the phthalein excretion and that of NaCl and N, and diet and treatment may be prescribed from the results of this test alone in cases which could not be recognized as chronic nephritis by other available clinical methods. A. P. LOTHROP.

Preparation of a dry urease powder and several properties of soy urease. MARTIN JACOBY AND SUGGA. Berlin. *Biochem. Z.* 69, 116-26(1915).—The soy bean meal is extd. 6 times with petroleum ether, then with 5 vols. H_2O for 16-24 hrs. at 0° , the ext. filtered or centrifuged and the soln. concd. to dryness in a stream of air at room temp., and the residue ground to a powder. This is difficultly and not completely sol. in H_2O . To test the activity of the preps. 20 cc. urea soln. (2%), 1 cc. toluene and 1 cc. olive oil were used. Treatment with alc. gives H_2O -insol. prepn. with about the same activity. Heating to 70° destroys a greater part of the activity of the urease, while 60° has very little effect. Trypsin digestion has no influence upon its activity. The action of papayotin, even at 60° , has no influence upon the activity, but if the urease-papayotin mixt. is dialyzed, there is a considerable decrease in the activity of the urease action. This may be due to the loss of auxosubstances, though the urease prepn. itself was not changed by dialysis. C. J. WEST.

Arginase. I. A new titrimetric method for the detection of arginase. ANTONINO CLEMENTI. Univ. Heidelberg. *Atti accad. Lincei* 23, II, 517-23(1914).—The new method is based on the action of arginase on arginine in H_2O giving 1 mol. urea + 1 mol. ornithine. By use of the formol titration method of Sørensen the presence of arginase may be detd. by detg. quantitatively the amt. of additional free NH_2 groups that it gives rise to by the hydrolytic decomp. of arginine into urea and ornithine. The theoretical considerations and experimental data on the behavior of arginine and ornithine and urea with respect to the formol titration show that this latter method is an appropriate method for quant. detns. of the hydrolytic action of arginase. The results obtained by the application of this method to the detection of arginase confirm the hypothesis and show that the action of arginase doubles the amt. of 0.2 *N* NaOH

required for the formal titration of the arginine salt used. Arginase is not only present in the juice collected with a Büchner press as found by Kossel and Dakin but also in the aq. ext. of mammalian livers.

E. J. WITZEMANN.

C. BACTERIOLOGY.

ERNEST D. CLARK.

A study of the "tellurite reaction" with the colon-typhoid group and other organisms. LEWIS DAVIS. *Centr. Bakt. Parasitenk., Abt. I* 75, 180-92 (1914).—Correction to abstract in *C. A.* 9, 923. In the sentence reading "with the colon bacillus, the 'tellurite (K_2TeO_3) reaction' is almost negative," the word "negative" should be "instantaneous."

E. J. C.

Production of lactic acid by acetic bacteria. A. OSTERWALDER. *Z. ges. Brauw.* 37, 35 (1914).—Certain acetic bacteria often produce lactic acid during fermentation, but only in presence of alc. Malic acid is attacked by these bacteria without formation of lactic acid.

J. GAUB.

New group of bactericidal substances derived from hexamethylenetetramine. WALTER A. JACOBS AND MICHAEL HEIDELBERGER. *Rockefeller Inst. Proc. Nat. Acad.* 1, 226-8 (1915).—While previous attempts to improve the action of $C_6H_{12}N_4$ (A) as an internal antiseptic have dealt chiefly with double salts with acids, phenols, and metallic salts, use is now made of the known fact that A functions as a tertiary base and forms quaternary salts with org. substances containing aliphatically bound halogen. These salts are almost all bactericidal, the action varying with the character of the halide used, and often being undiminished in the presence of serum. Aq. solns. of the salts soon decompose, forming finely divided ppts. of the methylene derivs. of the amines corresponding to the halides used, and to these are ascribed the bactericidal properties of the salts. In many instances the salts showed remarkable specificity when tested against different strains of bacteria. The chem. and bacteriological results are in course of publication.

M. HEIDELBERGER.

The proteolytic action of streptococci, staphylococci, and *Bacillus coli* cultures. EUGEN ROSENTHAL AND JOSEPH AUGUST PATAI. *Centr. Bakt. Parasitenk., Abt. I* 73, 406-13 (1914).—The curve of the production of amino acids by these organisms reached inside of 1 hr. a relatively high value which varied between 54.6 and 84.8 mg. of amino acid per 100 cc. of culture medium. There was not such a rapid rise on the 2nd day. The abs. amt. of amino acids produced by streptococci and staphylococci showed no difference but was considerably more than that produced by *B. coli*. Virulent organisms produced more amino acids than avirulent ones.

J. H. LEWIS.

The production of amylolytic and glucolytic bacterial enzymes. EUGEN ROSENTHAL AND JOSEPH A. PATAI. *Centr. Bakt. Parasitenk., Abt. I* 74, 369-73 (1914).—The curve of the production of amylolytic enzymes by different strains of streptococci, staphylococci, and *B. coli* rose gradually in height and reached its max. about the 9th or 10th day. The max. for the curve of glucolytic enzymes was reached on the 1st or 2nd day. The rate and amt. of production of the amylolytic enzymes by virulent and avirulent strains of the organisms showed no significant difference. The amt. of glucolytic enzymes produced by the virulent organisms is somewhat smaller than that produced by the avirulent ones.

JULIAN H. LEWIS.

The bacterial enzymes that liquefy gelatin and their antienzymes. P. BERTIAU. Louvain. *Centr. Bakt. Parasitenk., Abt. I* 74, 374-82 (1914).—The method of measuring bacterial action on gelatin which avoids the inconveniences of all others, in B.'s opinion, consists in measuring 1 cc. of a 10% soln. of gelatin into a series of test tubes. To these are added 1 cc. of dilns. of the enzymes in bouillon. After incubating 1 hr. at 37° the tubes are put into the ice-box. The amt. of digestion of the gelatin is meas-

ured by the solidity of the contents of the tubes, using as a control 1 cc. of the gelatin soln. plus 1 cc. of plain bouillon. Very active solns. of bacterial gelatinase can be obtained from bouillon cultures which contain a small amt. of gelatin and are freed of bacteria by filtration. By immunization of rabbits, very strong antienzymes which are specific can be obtained. Bacterial gelatinase is not to be confused with trypsin, as is shown in the expts. with antienzyme.

JULIAN H. LEWIS.

The bacterial action of glycerol on pathogenic bacteria. G. SKEFFERT. *Centr. Bakt. Parasitenk., Abt. I* 74, 644-50(1914).—A series of pathogenic bacteria was inoculated into a number of dilns. of pure glycerol with or without the addition of protein, and kept at different temps. for 45 days. The bactericidal action of glycerol was greatest at 37° and least at 0°. Its action was directly proportional to its conc. The effect of the presence of protein could not be detd. The bacteria studied are arranged in the order of their sensitiveness to glycerol.

JULIAN H. LEWIS.

The formation of hematoxin by cholera vibrios. OTTO LÖWY. Vienna. *Centr. Bakt. Parasitenk., Abt. I* 75, 319-29(1915).—In order to learn whether or not cholera vibrios can produce an hemolysin, a series of expts. was carried out with 103 strains of this organism isolated from stools during the Serb-Bulgarian war. It was found that none of these strains caused the laking of red corpuscles when grown on sheep or goat blood plates, or in broth containing the same kind of blood. They do, however, produce a proteolytic enzyme which decolorizes hemoglobin that has escaped from injured red cells. This enzyme is found in other than cholera vibrios. A centrifuged bouillon culture of the cholera vibrios did not cause hemolysis of washed guinea pig or rabbit corpuscles. It is decided that if a vibrio possesses hemolytic properties, it is not a cholera vibrio.

JULIAN H. LEWIS.

Is silica an indispensable constituent of plant food? MARSHALL LUNDIE. *S. African J. Sci.* 9, No. 10; *Chem. News* 110, 200-2(1914).—Wheat was grown to maturity on a water culture medium containing no silica. Silica is apparently not essential to plant growth but seems to have a protective influence against parasitic fungi (rust).

Notes on plant chemistry. P. Q. KEEGAN. *Chem. News* 110, 211-2(1914); cf. *C. A.* 8, 3667.

E. M. FRANKEL.

D. BOTANY

CARL L. ALSBERG.

Flow of protoplasm. G. LAKON. *Ber. botan. Ges.* 32, 421-9(1914); *Zentr. Biochem. Biophys.* 17, 409-10(1914).—The epidermis cells of onion skins constitute a peculiarly suitable object for the investigation and demonstration of protoplasm flow which appears here as the so-called circulation. It is quite immaterial whether sprouting onions or those freshly gathered or in winter rest are used. Osmotically active solns. promote protoplasm flow in the highest degree; the optimal conc. of such solns. depends on the osmotic pressure which prevails in the cells in question. This flow is entirely independent of any increased vitality of the cells; the phenomenon occurs with the same speed in resting organs as in those which are rapidly growing. Neither is protoplasm flow connected with the migration of material in the cells. Contrary to the case with the epidermis cells of onion skins, the action of salt solns. on the cells of the leaves of *Elodea canadensis* is minimal; a 0.005% H_2SO_4 soln. is, however, an especially suitable medium for producing a certain and lively flow of protoplasm in elodea. H_2SO_4 has no effect on protoplasm flow; simple injury by poisons is not sufficient to set the protoplasm in motion, a more sp. action of the poison being required. Protoplasm flow may be produced in elodea in growing the plants by allowing the tips of the shoots to project from the H_2O into the air.

H. S. PAINE.

Bacillus oxalatigenes N. sp.; is oxaluria of bacterial origin? D. DE SANDRO. *Portici. Il policlino*. 20, 138-44; *Zentr. Biochem. Biophys.* 17, 437(1914).—There was isolated from the feces of a woman a bacterium which produced short, very mobile rods in agar in a few hrs.; these rods showed a light-refracting central point (spore formation) which did not absorb aniline dyes and which gradually became larger and of oval shape. Ca oxalate crystals (the amt. of which gradually increased) were formed after 10-15 days when slices of potatoes with H₂O were inoculated with these bacteria and kept in an incubator. The name "oxalatigenes" is proposed for this bacterium on account of its property of producing oxalic acid. It is possible that this bacterium plays a role in the production of oxaluria. H. S. PAINE.

Protoplasm flow. F. JACOB. *Jena. Inaug. Diss.*, Jena, 1913, 52 pp.; *Zentr. Biochem. Biophys.* 17, 409(1914).—The membranes of the observed plant hairs (*Episcia cupreata*, *Gaura biennis*, *Onosma echinoides*) which exhibit protoplasm flow are very slightly permeable to H₂O and HgCl₂, but extremely permeable to O. When the hairs project from a medium which is impermeable to O, protoplasm flow continues longer than when O is excluded. The plant hairs are also capable of withdrawing from the plant the O which is required for protoplasm flow. A definite relation between O transport and protoplasm flow was not detected in the hairs which were studied; protoplasm flow is, however, distinctly dependent on the presence of O. A decrease in the duration of protoplasm flow was generally observed when inhibition of the latter by substances (paraffin oil, olive oil, etc.) impermeable to O was repeated. After cessation of protoplasm flow the latter responded readily to short aeration. H. S. PAINE.

Study of belladonna. W. UNGER. *Nouveaux remèdes; Giorn. farm. chim.* 62, 409(1913).—Belladonna adapts itself readily to varying environment, but the leaves and flowers are more luxuriant and the content of alkaloids is greater in the case of plants grown in the sun. The resp. contents of alkaloids in the fresh leaves of plants grown in the sun and those grown in the shade were as 518 to 331. H. S. P.

Some effects of the brown-rot fungus upon the composition of the peach. L. A. HAWKINS. *Am. J. Botany* 2, 71(1915).—In peaches rotted by the brown rot fungus, *Sclerotinia cinerea*, the pentosan content remains practically the same, the acid content is increased and the amt. of alc.-insol. substance which reduces Fehling soln. when hydrolyzed with dil. HCl decreases. The total sugar content decreases, while the sucrose practically disappears. J. J. SKINNER.

Normal and abnormal permeability. W. J. V. OSTERHOUT. *Am. J. Botany* 2, 93-4(1915).—O. answers the criticism of Höber on his investigations on the permeability of protoplasm, and states that he does not claim that the penetration in pure NaCl represents the normal condition. It is emphasized that in sea H₂O the permeability of *Laminaria* is much less than in pure NaCl, for other salts are present, especially CaCl₂, to antagonize the action of NaCl. Claim is made that there is no justice in speaking of normal impermeability of protoplasm to salts unless it is assumed to mean a rate of penetration lower than that found in dead cells. J. J. SKINNER.

Glucoside in the sunflower (ZANOTTI) 10.

Combustion processes in the organism. R. HÖBER. *Kiel. Z. Electrochem.* 19, 738-46(1914).—An address. E. M. FRANKEL.

Dextrinized malt in infant-feeding. THEODORE LE BOUTILLIER. *Am. J. Pharm.* 87, 162-3(1915).—A brief preliminary report of the result of adding dextrinized malt to milk mixts. in infant feeding, replacing the lactose formerly used. The general con-

clusions reached as a result of expts. carried on during the last 2 years are that malt sugar has marked advantage over either milk sugar or cane sugar in the feeding of infants unable to assimilate or thoroughly digest the milk sugar or cane sugar, and in the feeding of infants suffering from diarrhea.

W. G. GARSSLER.

The metabolism of vegetarians as compared with the metabolism of non-vegetarians of like weight and height. FRANCIS G. BENEDICT AND PAUL ROTH. Carnegie Inst. *J. Biol. Chem.* 20, 231-41(1915); *Proc. Nat. Acad. Sci.* 1, 100-1(1915).—Observations were made for the most part on members of the staff of the Battle Creek Sanitarium, Mich. The unit respiration app. was used and precautions were taken as to muscular repose, absence of food in the stomach and a non-febrile temp. Male vegetarians have a slightly less metabolism per kg. of body wt. and per sq. m. of body surface than have individuals of the same wt. and height on a mixed diet. The difference is very small and disappears altogether with female vegetarians. The basal gaseous metabolism is apparently not affected by living upon a vegetarian diet for a longer or shorter period. The av. respiratory quotient of 22 vegetarians was 0.83 compared with a quotient of 0.81 with 132 individuals on a mixed diet, indicating that vegetarians in the post-absorptive condition do not have available any larger proportions of glycogen than have non-vegetarians.

A. P. LOTHROP.

The metabolism of athletes as compared with normal individuals of similar height and weight. FRANCIS G. BENEDICT AND H. M. SMITH. Carnegie Inst. and Syracuse Univ. *J. Biol. Chem.* 20, 243-51(1915); *Proc. Nat. Acad. Sci.* 1, 102-3(1915).—The subjects were selected from among the students of Syracuse Univ. who were actively engaged in athletic sports from 1 to 3 hrs. daily and were distinctively trained athletes. The values for control individuals of approx. the same wt. and height were taken from a table published in a recent paper (cf. *C. A.* 8, 3318). None of the athletes showed a lower metabolism than the non-athletes and a very large proportion showed a considerable increase. The authors conclude "that the greatly increased proportion of active protoplasmic tissue present in the trained, hardened athlete is alone sufficient to account for the increase in the metabolism, and that this is not only an absolute increase, but from the nature of the comparison the metabolism is likewise increased per kg. of body wt. and per sq. m. of body surface. It would thus appear that the increase in the metabolism noted with athletes points strongly towards the earlier conception that the katabolism of the body is proportional not to the surface of the body, but to the active mass of protoplasmic tissue."

A. P. LOTHROP.

A comparison of the basal metabolism of normal men and women. F. G. BENEDICT AND L. E. EMMES. Carnegie Inst. *J. Biol. Chem.* 20, 253-62(1915); *Proc. Nat. Acad. Sci.* 1, 104-5(1915).—The values obtained in a study of the metabolism of 89 men and 68 women (cf. *C. A.* 8, 3318) are discussed and the metabolism of men and women are compared. The metabolism of men is about 5-6% greater than that of women of similar wt. and height, the difference being due to the fact that women probably have a larger proportion of subcutaneous fat, man therefore having a larger amt. of active protoplasmic tissue (cf. preceding abstr.). Most of the expts. were made with individuals between 20 and 30 years of age and hence no individual case can in any way affect the general deductions.

A. P. LOTHROP.

Factors affecting basal metabolism. FRANCIS G. BENEDICT. Carnegie Inst. *J. Biol. Chem.* 20, 263-99(1915); *Proc. Nat. Acad. Sci.* 1, 105-9(1915).—Body wt. affects the basal metabolism, larger bodies giving off more heat than smaller ones but there is no relationship between the total body wt. and the total heat production. Heat production is not detd. by body surface and a very large amt. of evidence points to the fact that the variations between metabolism and body surface are not due to errors in the formulas used for computing body surface. The proportion of inert

body fat and active protoplasmic tissue has a great influence as is indicated by the greater metabolism shown by athletes, taller individuals and by men as compared with women, the latter having a greater proportion of inert body fat. Another important factor is the stimulus to cellular activity which is influenced by age, sleep, diurnal variation, prolonged fasting, character of the preceding diet and the after-effects of severe muscular work. "It is clear that the basal metabolism of an individual is a function, first, of the total mass of active protoplasmic tissue, and, second, of the stimulus to cellular activity existing at the time the measurement of the metabolism is made. Apparently at present no law can be laid down that will cover both of these important variables in the basal metabolism of an individual."

A. P. LOTHROP.

The metabolic relationship of the proteins to glucose. N. W. JANNEY. Montefiore Home, N. Y. *J. Biol. Chem.* 20, 321-50(1915).—Expts. were performed using hardy mature dogs whose general tone remained excellent during the entire exptl. period. The animals were phlorhizinized and, after fasting 2 days, were fed diets containing ovalbumin, human serum albumin, gelatin, fibrin, edestin, gliadin and zein, all specially purified. Glucose and N were detd. hourly. Under optimal conditions the animal and vegetable proteins are metabolized at the same rate. All the extra glucose and N are eliminated by the 9th hour after ingestion. "Each protein produces a definite amt. of glucose in the phlorhizinized organism. The various yields represent 50-80% by wt. of the protein administered. These yields approximate the ratios which the glucogenetic amino acids of the proteins in each case bear to the total amino acids, as actually detd. by hydrolysis. From the standpoint of amt. at least, dextrose must be considered one of the chief intermediary products of protein metabolism, and of certain proteins the most important. The amts. of glucose yielded by the metabolism of proteins stand in no obvious relationship to their ability to promote growth." A. P. L.

The comparative nutritive value of certain proteins in growth, and the problem of the protein minimum. THOMAS B. OSBORNE AND LAFAYETTE B. MENDEL. Conn. Agr. Expt. Sta. and Yale Univ. *J. Biol. Chem.* 20, 351-78(1915).—Normal growth is completed satisfactorily on a diet containing a minimum of 12% casein. The addition of isolated cystine to the food containing 9% casein, without any other supplement, renders the ration decidedly more adequate for growth. With 9% edestin, the addition of lysine causes some improvement in growth, although not as marked as in the case of the cystine-casein mixt. Lactalbumin is much more efficient in promoting growth, for a normal rate is maintained on a diet containing only 9% lactalbumin, due probably to a more perfect balance in the proportions of the essential amino-acid groups it contains. "The economy of the different proteins as nutrients in growth appears to be closely bound up with their amino acid make-up." Failure to grow cannot usually be attributed to a lack of energy in the diet. To ascertain the protein minimum, exactly equiv. amts. of energy in the form of foods with unlike proportions of individual proteins should be fed, the minimum for growth or the limit of intake for maintenance being detd. by observing failure to make proper gains or to maintain wt. A. P. L.

The influence of the plane of protein intake on growth. E. V. MCCOLLUM AND MARGUERITE DAVIS. Univ. Wisconsin. *J. Biol. Chem.* 20, 415-28(1915); cf. C. A. 9, 642.—Rats were fed a mixt. of skim-milk powder, dextrin and butter-fat, the protein content of the ration varying between 2 and 10%. Other rations used for comparison contained 6% wheat protein, 4% wheat embryo protein or 2.45% egg protein. The lowest plane of protein intake derived from milk which can maintain young rats without loss of wt. is 3% of the food mixt. As the protein is raised between 3 and 8%, there is a progressive increase in the rate of growth. For a time rats may grow at about half the normal rate on a diet containing 6% wheat kernal protein but 2.45% of egg protein is not sufficient for maintenance without loss of wt. For a period of 6 weeks a ration

containing but 4% wheat embryo protein compares favorably with a similar plane of milk powder protein intake and is somewhat better than 6% of protein from the entire wheat kernel.

A. P. LOTHEP.

Origin of cholesterol. I, II. P. DEZANI. Turin. *Giorn. accad. med. Torino* 1914, 149-58; *Zentr. Biochem. Biophys.* 17, 416.—I. D. attempted to ascertain whether animals possess the power to produce the cholesterol essential to their development in case this compd. is excluded from their food. The cholesterol content of a number of white mice was detd., while other mice of the same litter were fed a mixt. of corn meal and casein which had been extd. for 6 days with alc. and Et_2O . These animals wasted away rapidly and all died within a period of 23 days. Detn. of cholesterol in the entire bodies of these animals, as well as in the feces, showed that no synthesis of cholesterol had taken place. D. was also able to det. that these mice had not utilized cholesterol in their metabolism. II. In a 2nd series of expts. mice were kept alive by gradually adding to the food (which had been extd. with alc. and Et_2O) the substances (salts, lecithin, fat) which are important in animal metabolism and which had been removed from the food by the original treatment. These animals developed in a perfectly normal manner; they were killed after 23 days and the cholesterol content of the entire body and feces was detd. The control animals which were killed at the same time showed an av. content of 0.182 g. cholesterol, while the mean cholesterol content of the exptl. animals was 0.242 g., thus indicating that a synthesis of cholesterol had occurred. Cf. C. A. 9, 1338.

Metabolism of white races living in the tropics. I. Protein metabolism. W. J. YOUNG. Australian Inst. Tropical Med. *Ann. Trop. Med.* 9, 91-108(1915).—No marked variations from the averages obtained in temperate climates were found. In every case the neutral S was high but whether this is due to an increased metabolism or not, only further expt. will show.

C. J. WEST.

Protein requirements under different conditions. The problem of the nitrogen minimum. EMIL ABDERHALDEN, GOTTFRIED EWALD, ANDOR FODOR AND CARL ROSE. Univ. Halle. *Arch. ges. Physiol.* 160, 511-21(1915).—The N minimum depends upon the compn. of the food, especially upon the content of N-free organic food. Expts. are reported dealing with diets of potatoes and Swedish bread. During the potato period an addition of 4.5 g. N is sufficient to maintain the N equil. 4.37 g. gave a slightly negative value while 4.98 g. gave a positive balance. Using Swedish biscuit 5.9 g. N were necessary to maintain an equil. Thus under these conditions the minimum is around 4 g. From a practical standpoint this value must be such that it will furnish the cells of the tissues with sufficient N-containing substances to enable them to perform their functions. During the expt. the uric acid and purine N excretion were const. Creatine was not excreted. The amt. of creatinine was const. During the bread diet the ammonia N was markedly increased.

C. J. WEST.

ABNORMAL.

Chemical and physiological studies of a man fasting thirty-one days. FRANCIS G. BENEDICT. Nutrition Lab., Carnegie Inst. Washington, *Publ. No.* 203, 416 pp. (1915).—Attention is called to the important relationship between numerous diseases and the various stages of nutrition and the fact that many pathological cases border on complete or nearly complete inanition, making a study of the physiology and chemistry of normal fasting of special importance. An extensive study of a Maltese was made. A preliminary period of 3 days with food, was followed by 31 days of complete abstinence from food and drink other than distd. water, and finally a 3-day realimentation period. The expt. was very successful in all except the last period, when, due to the fact that the subject insisted on breaking the fast by the consumption of excessive

METABOLISM CHART OF A MAN FASTING 31 DAYS

APRIL 14 - MAY 15, 1912

amts. of acid fruit juices, intestinal disorders developed. Measurements were made of the body wt., insensible perspiration, rectal temp. fluctuations, pulse-rate, blood pressure, and the morphology of the blood. The mechanics of respiration and the alveolar air tension were also observed. A complete clinical exam. was made every 2nd day with a record of subjective impressions and psycho-physiological observations. The intestinal flora were studied and the skin excretion detd. A complete chem. exam. was also made of the urine, including the partition of the Na and detns. of the Cl, P, S, total acidity, and β -hydroxybutyric acid. The mineral constituents, particularly the Ca, Mg, Na and K excretion, were studied and the reducing power, the C, and the energy of the urine were detd. Throughout the fast the urine was examd. daily with a microscope and tested for albumin. The study of the respiratory exchange was of special significance. In the respiration calorimeter it was possible to measure simultaneously the CO_2 excretion, the O consumption, and the water vaporized from the lungs and skin. Direct heat measurements, when corrected for body temp. fluctuations, gave the exact heat production. From the results obtained with the respiration app. B. studied the effect of various factors, such as changes in the body position, the work of writing, and breathing O-rich atms. upon the metabolism. The metabolism of the subject during sleep was compared with his metabolism in the waking condition. The energy transformation per kg. of body wt. and per sq. m. of body surface was computed. From the numerous respiration expts. with both app. and a careful record of daily activity, the total balance of income and outgo for this man for the 31 days could be computed with great accuracy. For the whole period the subject was able to exist in a fairly normal mental condition. It is impossible in a brief abstract to attempt an adequate summary of the results but the accompanying chart indicates the trend of some of the most important factors measured. FRANCIS G. BENEDICT.

Influence of the posterior lobe of the hypophysis on alimentary epinephrine and diabetes glucosuria. GIOVANNI QUADRI. Palermo. *Ann. clin. med. Palermo* 5, No. 2; *Zentr. Biochem. Biophys.* 17, 638-9(1915).—After a survey of the status of the present knowledge of the physiology and pathology of the hypophysis and its relation to the suprarenals with especial reference to carbohydrate metabolism, Q. discusses his own investigations. Ext. of the posterior lobe of the hypophysis was administered alone, as well as with epinephrine, to numerous individuals (with normal metabolism and free from fever) suffering from various chronic diseases. When the ext. was given in therapeutic doses, no glucosuria was produced, even in the case of simultaneous ingestion of an excess of carbohydrates; the prep. did not appreciably displace the limit of tolerance of the organism to the ingested sugar. The hypophysis ext. did not in the least intensify epinephrine glucosuria, but, on the contrary, when administered together with epinephrine, had a tendency to cause the disappearance of the glucosuria (which was produced solely by the epinephrine); glucosuria produced by epinephrine was greatly diminished in a severe case of diabetes mellitus. Ductless glands, internal secretions, and hormonal equilibrium. F. H. GARRISON. I. *Pop. Sci. Monthly* 85, 531-40(1914). II. *Ibid* 86, 92-9(1915). III. *Ibid* 142-52. —An historical review. F. G. MILLER, JR.

Relation between the calcium content of the bones and teeth of children. R. SIMONINI. Bologna. *Soc. med. chir.*, session June 11, 1913; *Zentr. Biochem. Biophys.* 17, 636-7 (1915).—S. attempted to det. whether there is any relation between the Ca content of the jaw bones and the teeth of children. The question was studied under physiol. and pathol. (rachitis) conditions and S. concludes that such a relation does exist, so that a reduced content of Ca in the jaw bones is usually coincident with delayed development and faulty structure of the teeth. H. S. PAINE.

Physiological-chemical problems in ophthalmology. A. JESS. Giessen. *Zentr. ges. Ophth.* 1, 209; *Zentr. Biochem. Biophys.* 17, 648 (1915).—J. reviews the recent work dealing with the physiol. chemistry of the crystalline lens. H. S. PAINE.

The constitution of milk. L. LINDET. *J. agr. prat.* 28, 277-8, 294-5 (1915).—In a study of the secretion of milk by the cow it is pointed out that the sum of the lactose and the salts of the milk is const. and in osmotic equil. with the sol. elements of the blood of the cow. The function of the lactose and sol. salts is to dissolve the casein produced by the cow, forming a colloidal suspension which coagulates under the influence of pressure or of acid fermentation. The ash of the casein was found to be composed of P_2O_5 of organic origin and $CaH_4(PO_4)_2$ which are sol. in H_2O . The fatty matter is in emulsion in the form of minute globules in the serum, sol. in the curd. J. J. SKINNER.

Physiology of the thyroid gland. E. P. HAÜSSLER. *Schweiz. Apoth. Ztg.* 53, 32-7, 46-9 (1915).—A summary of the main known facts and theories, and the results of recent work of F. Blum and co-workers. Cf. *C. A.* 8, 145, 3570, 3587, 3588.

S. WALDBOTT.

Composition of flesh with different diets. G. DIESSELHORST. *Arch. ges. Physiol.* 160, 522-4 (1915); cf. *C. A.* 5, 3600.—Because of exptl. difficulties, the earlier conclusions are probably incorrect and worthless. C. J. WEST.

Blood characters: their variability and interdependence. W. F. HARVEY AND H. W. ACTON. *Indian J. Med. Research* 2, 721-32 (1915).—There is little variation in the resistance of red blood corpuscles to the action of hypotonic solns. either among individuals themselves or as between individuals on their 1st arrival at a high altitude and after residence there for 14 days. The same applies to the Cl content of the blood serum. No. and vol. of red blood corpuscles, sp. gr., and hemoglobin content of the blood vary to a considerable extent in conditions of apparent health. These are greater in the Indian than in the European. The correlation between such characters as mentioned above is close. There is an increase in these characters with residence at a high altitude. C. J. WEST.

Arginase. II. The distribution of arginase in the organism and in the class vertebrates. ANTONIO CLEMENTI. Univ. Heidelberg. *Atti accad. Lincei* 23, II, 612-6 (1914).—By applying the method described in *C. A.* 9, 1492, C. verified in general the results obtained by Kossel and Dakin by the $AgNO_3$ pptn. method. In the vertebrate series arginase occurs in the livers of mammalia, amphibia and fish but it is absent in livers of birds and most reptiles. Arginase is also present in the kidneys of mammalia, but in these organs the arginase is not detected by H_2O extn.; it is sepd. with a Büchner press. Likewise arginase was found to be absent in aq. ext. of the spleen, intestinal mucosa and muscles of mammalia, birds, amphibia, reptiles and fish. The kidneys of birds like livers of mammalia, etc., show arginase in the aq. ext. of the tissue, in which respect they are exceptional. The following relations as to the function of arginase in the organism are pointed out: (1) The absence of arginase in the liver of only those vertebrates in which the liver elaborates uric acid in place of urea (birds and reptiles); and the presence of it in all of the remaining vertebrates the livers

of which elaborate urea (mammalia, amphibia and fish). (2) The presence of arginase in the kidneys of mammalia but the impossibility of obtaining it by simple aq. extn. of the kidney tissue of all classes of vertebrates (birds excepted). The above observations prove the effective participation of arginase in the liver in the formation of urea. Some other deductions are given.

Reply to M. Cloetta and E. Anderes "do the lungs possess vasomotors?" ERNST WEBER. Berlin. *Arch. Physiol.* 1914, 533-52; cf. C. A. 8, 3471. C. J. WEST.

G. PATHOLOGY.

H. GIDEON WELLS.

The influence of salt-concentration on hemolysis. W. W. C. TOPLEY. London. *Proc. Roy. Soc. London (B)* 88, 396-408(1915).—In hemolysis of sheep corpuscles by guinea-pig complement it is found that (a) the presence of an excess of an electrolyte (NaCl) above the normal limit in a hemolytic mixt. prevents the combination of the complement with the red-cell-antibody complex; (b) if the conc. of the antibody be markedly increased it is possible, up to a certain point, to counteract the effect of the increased salt conc.; (c) if the salt conc. be decreased, a decreasing conc. of antibody serves to produce the union of red cells and complement; (d) in an almost completely salt-free medium the combination occurs in the complete absence of antibody.

A. T. CAMERON.

The cerebrospinal fluid in pellagra. W. F. LORENZ. *Pub. Health Reports* 29, 2360-3(1914).—Pressure estns. of the spinal fluid are of doubtful value since very high tension can be obtained in various meningitides, and for this reason an app. is not needed. A lymphocytosis of the cerebrospinal fluid does not occur in uncomplicated pellagra. Globulin excess of the spinal fluid is only occasionally observed. Lange's colloidal AuCl₃ test is uniformly negative in pellagra. The Wassermann is negative except in moribund cases which gave weakly positive reactions with blood serum. The spinal-fluid findings seem inconsistent with the idea that pellagra is an infectious disease of the central nervous system.

J. GAUB.

Further researches on chronic alcoholism and anaphylaxis. E. MANOILOV. *Centr. Bakt. Parasitenk., Abt. I* 73, 314-6(1914).—The author, with Zboromirsky, had previously shown that the serum from a chronic alcoholic will, when injected intravenously or intraperitoneally, make a rabbit or guinea pig sensitive 48 hrs. later to a dose of alc. (given intravenously) that causes no symptoms in a normal animal. In addition, M. gave rabbits and guinea pigs repeated intravenous injections of alc. Inactivated serum from these animals injected into normal ones, made them hypersensitive to a small dose of alc. injected 48 hrs. later intravenously. The symptoms produced in the hypersensitive animals were similar to those of anaphylaxis.

J. H. LEWIS.

Immunization with tetanus toxin-antitoxin mixtures. M. v. EISLER AND E. LOWENSTEIN. *Centr. Bakt. Parasitenk., Abt. I* 75, 348-64(1915).—Guinea pigs given a single injection of tetanus toxin neutralized with antitoxin exhibit no immunity, but if the same mixt. is given the 2nd time, 10-50 days after the 1st injection, they will form within 15-25 days a large amt. of antibody in the circulation. In rabbits, however, a single injection of neutralized toxin did produce immunity. The cells of the guinea-pig tissues *in vitro* are not able to break up the union between toxin and antitoxin, but the liver cells of the rabbit are. The injection of rabbit liver into a guinea pig does not confer upon the latter the power of forming antitoxin after a single injection of the neutralized toxin. Kaolin, like rabbit liver cells, can break up the union between toxin and antitoxin.

JULIAN H. LEWIS.

The non-protein nitrogenous compounds of the blood in nephritis, with special reference to creatinine and uric acid. VICTOR C. MYERS AND MORRIS S. FINE. N.

Y. Post-Graduate Med. School. *J. Biol. Chem.* 20, 391-402(1915).—Concs. of uric acid of 27 mg. per 100 cc. of blood and of creatinine of 33.3 mg. were encountered in cases of nephritis. The retention of these substances is not in itself the cause of uremic symptoms as, in a case of HgCl_2 poisoning, uremic symptoms did not appear until more than a week after the max. concs. of uric acid and creatinine had been observed. A marked rise in uric acid was accompanied by an increase in creatine, pointing to increased tissue destruction as the source of the uric acid. In the spinal fluid the amts. of creatine and uric acid were very low or absent while the conc. of urea and creatinine approached that found in the other tissues in uremia. Some parallelism appeared to exist between the accumulation of urea and creatinine and between uric acid and creatine. In 6 cases of gout the uric acid in 100 cc. of blood ranged from 3.8 to 5.8 mg., values very much lower than found in cases of uremia. ALFRED P. LOTHROP.

Some observations on hypersensitiveness to pneumococcus protein, with special reference to its relation to immunity. PAUL W. CLOUGH. Johns Hopkins Univ. *Bull. Johns Hopkins Hosp.* 26, 37-44(1915).—"Protein" exts., obtained from pneumococci by a modification of Besredka's method, sensitized normal guinea pigs and specifically intoxicated suitably sensitized guinea pigs but would not uniformly cause acute fatal reactions in sensitized animals. After extn., heating for 1 hr. at 60° greatly reduced the toxicity of the ext. due to autolysis during extn. A very slight grade of immunity to infection by living virulent cultures appeared inconstantly in guinea pigs sensitized with exts. of pneumococci and animals highly immunized by repeated subcutaneous injections of living virulent cultures showed also a marked degree of hypersensitiveness to pneumococcus exts. In patients with pneumonia a condition of hypersensitiveness to pneumococcus "protein" could not be demonstrated by local application of protein soln. to the conjunctiva or by intracutaneous injections.

A. P. LOTHROP.

Factors of coagulation in the experimental aplastic anemia of benzene poisoning with special reference to the origin of prothrombin. S. H. HURWITZ AND C. K. DRINKER. Boston. *J. Exp. Med.* 21, 401-24(1915).—Subcutaneous injections of C_6H_6 in rabbits produce marked destructive changes in the hematopoietic organs, especially in the myeloid tissue. C_6H_6 poisoning registers a change not only in the formed elements of the blood but also in the factors of coagulation. The circulating prothrombin is considerably reduced in amt. and in most instances the animals show aplasia of the bone marrow. The extreme aplasia of the marrow without a fatal diminution in the circulating prothrombin suggests that either other tissues and organs in addition to the bone marrow are concerned in the prothrombin formation or a minimum amt. of myeloid tissue suffices to maintain the quant. of prothrombin above a dangerous level. The myeloid tissue plays no part in the production of antithrombin. Bone marrow activity is not essential for the production of fibrinogen.

G. M. MEYER.

Studies on immunity. II. Nature of anaphylatoxin. J. BRONFENBRENNER. Pittsburg. *J. Exp. Med.* 21, 480-92(1915); cf. *C. A.* 9, 920.—The union of fresh serum of pregnant or immunized animals with the corresponding boiled protein (substratum) is accompanied by the formation of poisonous substances. The poison originates from the serum as a result of autodigestion and not from the substratum. The process of autodigestion may be detd. by the specific or non-specific removal of the antitypsin of the serum. The poisons originating from the serum are toxic only for homologous animals. The autodigestion of the serum, if allowed to proceed far enough, may go beyond the toxic stage. The biological properties of these poisons indicate their close similarity to the anaphylatoxin and suggest that the anaphylatoxin of Friedberger is the product of the autodigestion of serum and not of the protein outside of the serum.

G. M. MEYER.

Notes of further observations upon dyspnea and its relation to blood reaction. THOMAS LEWIS AND JOSEPH BANCROFT. Cambridge. *Quart. J. Med.* 8, 97-113 (1915).—It seems possible that many cases of spasmodic dyspnea may result from the sudden flooding of the system with acid products. JOHN T. MYERS.

The rationale or modus operandi of the Wassermann reaction and Abderhalden test. J. E. R. McDONAGH. *Quart. J. Med.* 8, 130-55(1915).—When once a serum has had its adsorption capacity increased, as occurs to the lipoid globulin mol. in a syphilitic case, it is always liable to exhibit the same phenomenon when given the opportunity. Several factors may be responsible for a positive reaction: an excess of lipoid over the protein, a breaking down of the huge lipoid mol. into several smaller ones, and an excess of fatty acids or amino acids. These causes cannot be prevented or differentiated; therefore a positive reaction is not necessarily indicative of syphilis. Since a free fatty acid or a free amino group can inhibit a positive reaction, a negative reaction cannot exclude syphilis. Once the body has had to form a protective substance it goes on forming it after the attaching force has vanished. In the case of syphilis the protective substances are lipoid-globulin complexes which emanate from the lymphocytes. Their production may go on at an ever-increasing rate until the power of the lymphocytes is overtaxed. No relation exists between the positivity of reaction and the oxidase content. In the Abderhalden test it is the oxidase and not the lipoid globulin itself which is responsible for the breaking down of the organ, but the latter has the specific stereochemical configuration. The oxidase is non-specific. There is no evidence that the breaking down of the organ is proteolytic or peptolytic. It may be that all enzymes are oxidases and that the differences in action rest in the stereochemical molecular configuration of the radicals to which the oxidases are attached by means of the ions. Any modification of method which relies on the patient's own serum must be untrustworthy. A standardized complement must be used. Cholesterolized antigen should not be used since any attempt at sharpening the reaction will increase the % of positive results with normal serum. JOHN T. MYERS.

Quincke's disease and pregnancy. G. BALLERINI. Parma. *Ann. ostetr.* 1913, 266-80; *Zentr. Biochem. Biophys.* 17, 426-7(1914).—In the observed cases of angioneurotic, transitory edema (Quincke's disease) during pregnancy G. concludes that the angioneurotic disturbances are an expression of a hyperfunction of the thyroid with overproduction of stimulative hormones; in 1 case the angioneurotic symptoms and cardiac neurosis disappeared after thyroïdin treatment. The Abderhalden reaction indicated the presence of enzymes with a sp. cleaving action on thyroid albumin.

H. S. PAINE.

Remarkable differences in the appearance of anaphylactic inflammation of the cornea in various animals. KÖLLNER. Würzburg. *Arch. Augenheilk.* 77, 289; *Zentr. Biochem. Biophys.* 17, 662-3(1915).—Exptl. anaphylactic corneitis which occurs so readily in rabbits is not produced in all animals in the same manner. Dogs were the only exptl. animals employed which regularly exhibited corneitis as intense or even more intense than that shown by rabbits after injection of horse, cattle and rabbit sera and egg albumen between the corneal lamellae. Guinea pigs, cats and monkeys either showed no atypical changes at all or at most only isolated changes of such a character that it was impossible to det. definitely whether they represented a local hypersensitiveness reaction. At any rate, the latter did not vary in a parallel manner with the degree of the anaphylactic general reaction which was different for the various animals.

H. S. PAINE.

Bence-Jones albuminuria. A. KIMMERLE, O. SCHUMM AND E. FRAENKEL. Hamburg. *Eppendorfer Festschr.* 1914; *Zentr. Biochem. Biophys.* 17, 436(1914).—In the case examd. the urine contd. 2.5-3.5 pts. per mill. of albumin, most of which was due

to the Bence-Jones protein. The urine at times contained some globulin and also traces of nuclealbumin, but no histone. A carefully executed detn. of the coagulation point is very important for the detection of the Bence-Jones protein in urine; the latter only varied to a relatively slight extent during a month period of observation. Pathol.-anatomical investigation indicated a combination of cancerous affection of the liver with extended myelomatosis of the skeleton to which excretion of albumin is to be referred.

H. S. PAINE.

Cholesterol in blood during pregnancy. M. HUFFMANN. *Zentr. Gyn.* 39, No. 3(1915); *J. Am. Med. Assoc.* 64, 865.—The cholesterol content of the blood gradually increases during gestation, reaching its highest point in the last months, then drops to normal in 8 or 10 days, irrespective of lactation.

L. W. RIGGS.

Nature of the idiosyncrasy to egg protein in human beings. Preliminary note. JACOB BRONFENBRENNER, *et al.* Pittsburgh. *J. Am. Med. Assoc.* 64, 1306-7(1915); *cl. C. A.* 9, 920.—Freshly drawn serum of a patient who was subject to asthmatic and severe gastrointestinal disturbances following the ingestion of egg protein, drawn shortly after an attack, was tested by the Abderhalden method with coagulated egg white as substratum. The result showed beyond doubt that the patient's blood contained specific antibody against the egg protein.

L. W. RIGGS.

Gallstones result of transient thickening of the bile. T. ROVSING. *Hospitalstidende* 58, No. 11(1915); *J. Am. Med. Assoc.* 64, 1460.—Bile, like urine, may become abnormally conc. during the course of a febrile disease. Chem. exam. of gallstones from 200 cases showed that freshly deposited stones and all nuclei of gallstones consisted of bile pigment and Ca. The bacteriological exam. of 320 removed gall bladders showed 54% to be entirely sterile, contrary to Naunyn's theory that gallstones are deposited in consequence of an infectious process.

L. W. RIGGS.

The cerebrospinal liquid in tetanus. C. FERRIER. *J. pharm. chim.* 11, 21-2 (1915).—In each of 6 cases of tetanus some cerebrospinal liquid was withdrawn before injection of serum. The reaction was slightly alk. Exam. showed absence of bacteria and of leucocytes, but excessive amts. of dextrose (0.7-0.93 g. per l.) and urea (1.000-1.350 g. per l.), also NaCl (6.6-7.5 g. per l.) and traces of globulins. S. WALDBOTT.

Pathogenesis of diabetes mellitus. A. MASSAGLIA. Univ. Modena. *Centr. allgem. Path.* 21, 65-72(1915).—The function of the pancreas in carbohydrate metabolism is regulated by several other organs, and diabetes may depend on hypofunction of 2 or more organs in each of which taken alone lesions are not found of sufficient degree to account for the diabetes. The spleen is one of the organs producing an internal secretion that acts on the pancreas. Injury to the carotid glands may cause glucosuria if there is hypofunction of the pancreas and other glands. H. G. W.

Passive anaphylaxis and its serological estimation for determining the value of immune sera. MINORU TANAKA. Osaka, Japan. *Z. Immunität.* 23, 389-401(1915).—By injecting antibacterial sera into guinea pigs the animals are made passively anaphylactic to the specific bacteria, which is manifested by a typical fall in temp. after injection of a small amt. of bacterial suspension (0.01 cc.) and typical anaphylactic death after 0.5 cc. It is suggested that the degree of passive sensitization may be found of use in estg. the activity of antibacterial sera.

H. G. W.

The proteolytic power of the blood in anaphylaxis. EDGARD ZUNZ AND PAUL GRÖRGY. Univ. Brussels. *Z. Immunität.* 23, 402-25(1915).—After an intravenous sensitizing dose of ox serum into the dog there appears a specific proteolytic power of the dog blood for ox serum, which can be demonstrated by van Slyke's method for detg. free amino N. This property appears between the 5th and 11th days, reaching its max. after 15 days, and coincides with the appearance of anaphylactic sensitiza-

tion. During anaphylactic shock the proteolytic power disappears, but 4 to 10 days later it is stronger than before. The blood plasma of a sensitized dog shows no demonstrable increase in amino acids, but the uncoagulable blood of a dog dead from anaphylactic shock does contain an excess of amino N. H. G. W.

The gold reaction in the cerebrospinal fluid. WILHELM SPÄT. Kladno. *Z. Immunität.* 23, 426-42(1915).—The gold reaction of Zsigmondy is strongest and most characteristic in paresis and tabes, less constant but characteristic in lues and irregular and not to be interpreted in meningitis. Occasionally positive reactions are observed even in normal fluids. The gold reaction depends upon a reaction on the luetic antibody, which is strongest in paresis, nearly or quite as strong in tabes, and weakest in fresh lues. The positive reactions of normal or meningitis fluids are caused by variations in the protein content. The fact that the color change or pptn. of the Au is usually most marked in high dilns. corresponds to the reaction optimum conc. in immune reactions. The influence of heat on the fluid or the Au indicates that this reaction corresponds to an immune reaction with an inorganic colloid as antigen. H. G. W.

Comparison of the antibody production by antigens prepared by different methods. H. REITER AND S. SILBERSTEIN. Univ. Königsberg. *Z. Immunität.* 23, 443-72 (1915).—Various bacteria killed by different methods are used as antigens, and the alterations in the agglutinin and bacteriotropinogen groups were found not to be affected in parallel degree, the latter being the more resistant. Killing by CHCl_3 had less deleterious effect than killing by 60° or phenol, the latter being more injurious than 60° ; ether came between CHCl_3 and heat; formaldehyde gas had less effect than CHCl_3 , and ozone is nearly as good. Antiformin destroys practically all the agglutinin, but part of the tropinogen remains. H_2O_2 is more injurious than heat, and lactic acid gives variable results. H. G. W.

The peptolytic enzymes in the urine of rabbits after burning or photodynamic injury. HERMANN PFEIFFER. Univ. Graz. *Z. Immunität.* 23, 473-514(1915).—The most constant symptom of burning or photodynamic injury in rabbits is the presence in the blood stream of an enzyme that splits glycyiltrypophan, which is also excreted in the urine. It is present in cases that recover, but less in amt. than after fatal injury. It does not come exclusively from the hemolysis. Sera of burned rabbits kept 2 hrs. at 56° show a pptn. which is approx. parallel to the amt. of enzyme; sometimes a similar pptn. takes place in the urine of the same animals. It was also found that exts. of organs containing the same enzyme undergo spontaneous pptn. at 56° , the kidney exts. containing the most. By mixing tissue exts. with normal rabbit tissues and injection into rabbits, sera are obtained which possess the properties characteristic of serum of burned rabbits; hence the conclusion is drawn that perhaps the enzyme found in burned rabbits results from the entrance into the blood of substances derived from the injured tissues. Possibly similar processes occur when other causes of tissue destruction produce similar conditions. The relation of these phenomena to the protective enzymes of Abderhalden was not detd., but is discussed. H. G. W.

Dependency of the destruction of complement upon the presence of oxygen. MARTIN JACOBY AND MARGARETE JACOBY. Berlin. *Biochem. Z.* 69, 127-33(1915).—If the O is entirely removed from a serum by a current of H it cannot be inactivated by shaking (*C. A.* 4, 1198). Such a serum is quite stable and air can be passed through it for some time before it can be inactivated by shaking. It is possible that in an O-poor medium the complement changes into a stable modification. C. J. WEST.

Agglutinins in the blood of cholera cases. E. D. W. GRIFF. *Indian J. Med. Research* 2, 733-62(1915).—The results of 363 cases are given in a series of charts and protocols. C. J. WEST.

Quantitative research on the phenomena of bacteriolytic sensibilization. F. PORCELLI-TITONE. Univ. Naples. *Atti accad. Lincei* 23, II, 472-7(1914).—The phenomenon through which the bacteriolytic sensitizer is bound to the protoplasm of bacteria is quantitatively regulated by the same laws, according to which the hemolytic sensitizer fixes itself to the erythrocytes, and agglutinin to the corresponding bacterial bodies. In such immunity reactions, antibody and antigen are not combined according to a const. quant. ratio. The quantity of antibody that combines with a given quantity of antigen increases with the increase of the conc. of the antibody in the surrounding liquid. The ratio between the quantity of antibody that is bound to the antigen and its initial conc. in the liquid diminishes as the conc. increases. Between the quantity A of an antibody that combines with any unit of vol. of antigen and the amt. B that remains free in any unit of vol. of surrounding liquid, it seems that the equil. $A = kB^{1/2}$ exists, according to which for 3 mols. bound there will be 2 free. The hypothesis that the antibody is divided in the antigen and in the surrounding liquid as in 2 different solvents where it assumes different mol. wts., seems quite probable.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

The antagonistic action of carbon dioxide and epinephrine on the heart. S. W. PATTERSON. Univ. Coll., London, and Univ. Berlin. *Proc. Roy. Soc. London (B)* 88, 371-96(1915).—The expts. were on the heart-lung prep. described by Knowlton and Starling, for the most part with dogs (a few on cats). The results show that CO_2 alone depresses all the functions of the isolated heart. Epinephrine besides dilating the coronary vessels has a sp. action in increasing the rate and strength of ventricular contraction. The effect of CO_2 and epinephrine combined is still to allow of more rapid and stronger contraction and rapid relaxation, and also to lengthen the diastolic period. Thus greater filling of the heart takes place and the heart is in better condition for putting out a maximal output.

A. T. CAMERON.

Physiological and therapeutic action of renal extract on thyroidectomized animals. CARLO ONESTI. Univ. Parma. *Arch. farm. sper.* 19, 28-62(1915).—The survival of thyroidectomized animals subjected to renal opotherapy exceeds that obtained by other investigators who used other methods of treatment. After each administration of the renal prepn. there is a distinct modification of diuresis, with increase in vol. and sp. gr. of the urine and a change from alk. to acid reaction. At the same time the general condition of the animal improves perceptibly.

A. W. DOX.

The action of sugars on the blood vessels. UBALDO SAMMARTINO. Univ. Rome. *Arch. farm. sper.* 19, 170-92(1915).—Small doses of sugar are followed by vaso-dilation and increase in volume of urine, while large doses result in vasoconstriction and decreased secretion.

A. W. DOX.

Use of radioactive substances for destroying living tissues. O. HERTWIG. Berlin. *Sitz. kgl. preuss. Akad.* 1914, 894-903.—Action of radioactive substances on body tissues is elective. It is most powerful on nuclei and embryonic cells. Ova and sperms are very markedly affected by even brief exposure to the emanation of small amts. of Ra. H. studied the action on *Hedra helix*, *Sedum spectabile* and cocainized tadpoles and found that exposed parts soon atrophied. H. could not confirm the statement that emanation from small doses of Ra had an accelerating effect on tumor growth.

E. M. FRANKEL.

Changes in the cerebrospinal fluid after the administration of neosalvarsan. W. KERL AND H. KÄHLER. Vienna. *Wien. klin. Wochschr.* 27, 1098-1101(1914).—In most cases administration of neosalvarsan resulted in an increased sugar content of the cerebrospinal fluid.

H. B. LEWIS.

The influence of thyroid derivatives on the lungs. B. ZONDEK AND W. FRANK-FÜRTER. Berlin. *Arch. Physiol.* 1914, 565-84.—Thyroid ext. and iodothylin caused bronchoconstriction and a dilatation of the capillaries of the lungs. This action is not due to the choline or I content of the thyroid or to the presence of a foreign protein. H. B. LEWIS.

Studies in the biochemistry and chemotherapy of tuberculosis. XII. The action of sodium thiocyanate in tuberculosis. HARRY J. CORPER. Chicago. *J. Infect. Dis.* 16, 38-46(1915).—In search of a chemotherapeutic agent of value in tuberculosis, C. studied the toxicity of NaCNS, its distribution in the tissues of exptl. animals, and its tuberculocidal action. This substance is lethal for rabbits when given intravenously in amts. of 0.4-0.6 g. per kg. Delayed death may occur even from smaller doses. When injected intravenously (0.4 g. per kg.), it is found in the tuberculous tissues in concs. about equal to that in the blood (0.06-0.08%). The conc. in the lungs, heart, kidneys, and testes is not far from that in the blood. The conc. in the liver is less, while it is practically absent from the muscles. It disappears from the tissues (normal and tuberculous) as speedily as it does from the blood, being absent in about 5 days after injection. No evidence of chem. affinity of the NaCNS for any of the normal or tuberculous tissues was obtained. Tubercle bacilli, exposed to concs. of NaCNS up to 1% for 48 hrs. at 37° and up to 0.1% for 7 days at 37° were not killed. No evidence of attenuation was observed. JULIAN H. LEWIS.

An experimental study of lavage in acute carbolic acid poisoning. DAVID I. MACHT. Johns Hopkins Univ. *Bull. Johns Hopkins Hosp.* 26, 98-104(1915).—Carbolic acid in the form of U. S. P. phenol liquefactum was administered to dogs and cats by means of a stomach tube, followed by lavage at different periods of time after the appearance of toxic symptoms. Plain H₂O, aq. solns. of alc. and conc. solns. of Na₂SO₄ were used for washing out the phenol. The chances of recovery depend on the amt. of phenol swallowed, on the promptness with which lavage is begun and on the soln. used for lavage. Food in the stomach greatly increases the chances of recovery. A conc. soln. of Na₂SO₄ is the most efficient agent, recovery being effected in one dog by lavage with such a soln. 45 min. after the first dose of phenol and after a dose of 22 cc. had been given. The action of the Na₂SO₄ is not a chem. one but is probably due to the hindrance of absorption and possibly also to purgation. Administration of alc. after poisoning aggravates the symptoms and hastens death but an animal intoxicated with alc. withstands better the effects of phenol taken afterwards. "*The use of alc. in carbolic-acid poisoning should therefore be strongly discouraged.*" If a soln. of Na₂SO₄ is not available, H₂O is the most efficient medium to employ. Expts. were also made using egg albumen, Na₂SO₄, lime H₂O and syrup of lime but none of them proved satisfactory. A. P. LOTHROP.

Studies in carbohydrate metabolism. VIII. The influence of hydrazine on the utilization of dextrose. FRANK P. UNDERHILL AND ALBERT G. HOGAN. Yale Univ. *J. Biol. Chem.* 20, 203-10(1915).—Hydrazine sulfate (75 mg. per kg.) injected subcutaneously into rabbits causes hypoglycemia but not so consistently as in dogs. Estn. of the amt. of blood sugar shows a marked retardation in the utilization of dextrose injected subcutaneously 2 days after the injection of hydrazine. The diminution of dextrose in the blood after hydrazine poisoning is not explained by any of the results obtained and cannot be due to any increase in the glucolytic processes as, if such were the case, injected glucose would be more quickly disposed of than in the normal rabbit. IX. **The influence of hydrazine on the glyoxalase activity of the liver.** *Ibid* 211-5.—The glyoxalase activity of the liver of dogs poisoned by the subcutaneous injection of 50 mg. of hydrazine sulfate per kg. was quant. detd. by estg. the amt. of mandelic acid formed from 0.2 g. of phenylglyoxal by 50 cc. of 20% tissue ext. in periods

ranging from 30 min. to 9 hr. The glyoxalase activity is not altered to any appreciable extent by the action of hydrazine and the disappearance of glycogen from the liver and the diminished blood sugar content after hydrazine poisoning cannot be due to any interference with the activity of glyoxalase, which is concerned in the intermediary metabolism of carbohydrates.

ALFRED P. LOTHROP.

Collected abstracts from the field of pharmacology (Oct. to Dec., 1914). CARL BACDEM. Bonn. *Zentr. inn. Med.* 36, 161(1915).

JOHN T. MYERS.

Influence of Röntgen rays on the formation of bone callus. K. SALVETTI. *Deut. Z. Chir.* 128, 130-8; *Zentr. Biochem. Biophys.* 17, 412(1914).—The formation of callus is at first disturbed by the action of Röntgen rays; the deposition of Ca salts is, however, promoted.

H. S. PAINE.

Poisoning by calomel after drinking of Vichy water. SPINDLER. *Presse méd.; Giorn. farm. chim.* 63, 205(1914).—Symptoms of acute intoxication were observed in an infant after ingestion of HgCl followed by drinking of Vichy H₂O; intoxication was probably due to a reaction between HgCl and the alkali.

H. S. PAINE.

Influence of iodine on the phenomenon of autolysis. L. KEPINOV. *Nouveaux remèdes; Giorn. farm. chim.* 62, 271(1913).—The introduction of I considerably intensifies hepatic autolysis; KI produces no effect. Injection of Lugol's caustic intensifies autolysis, but not when the exptl. animal dies by the injection. The serum of the animals may acquire autolyzing properties. The antitryptic index is increased by I and KI.

H. S. PAINE.

Mushroom poisoning. M. CLARK, *et al.* Baltimore. *J. Am. Med. Assoc.* 64, 1230-2 (1915).—The pathological picture in these cases resembled that in P poisoning and led to the exam. of the functional condition of the liver and kidney, with the finding of an extremely impaired renal function as shown by the inability to excrete phenolsulfonephthalein, the very high total non-protein and urea N of the blood, the lowered f. p. of the serum, and the absence of diastatic activity in the urine. The positive findings in the galactose test and the high conc. of amino acid in the blood would point to decreased function in the liver. The combination of increased excretion of urine with large excretion of N in association with cumulative phenomena in the blood has also been observed in P poisoning in dogs and in uranium nephritis. Cf. C. A. 8, 1438, 1971, 3803.

L. W. RIGGS.

Chemotherapy and tumors. RICHARD WEIL. New York. *J. Am. Med. Assoc.* 64, 1283-9(1915); cf. C. A. 8, 181.—W. gives a critical discussion of the use of cryst. salts of Se, colloidal Se, colloidal metals, and compds. of metals with organic radicals in the treatment of tumors.

L. W. RIGGS.

Presence of arsenic in the spinal fluid. GEO. W. HALL. Chicago. *J. Am. Med. Assoc.* 64, 1384-5(1915).—Following the administration of Na cacodylate and Na arsenate in varying therapeutic doses, the spinal fluid showed the absence of As. The administration of neosalvarsan was followed by the detection of As in 4 out of 20 cases, and following salvarsan in 2 out of 3 cases.

L. W. RIGGS.

Toxicity of ascarides. A. BRINDA. *Arch. med. enfants* 17, Nos. 11-12(1914); *J. Am. Med. Assoc.* 64, 1035.—The expts. show the extremely toxic action of ascarides ext., the action being evident on the circulation, pulse, blood pressure, respiration, and in the pathologic-anatomic findings. The juice squeezed from ascarides induces convulsions and hemolysis. The evidence points to an extremely active toxalbumin.

L. W. RIGGS.

Hexamethylenamine as disinfectant for the urinary apparatus. H. F. HOST. *Norsk Magazin Laegevidenskaben* 76, No. 2(1915); *J. Am. Med. Assoc.* 64, 1118.—H.'s research indicates that, following the administration of hexamethylenamine,

HCHO is found in the urine in amts. proportional to the conc. of the H ion and the time allowed. It is partially sepd. in the stomach into HCHO and NH_3 , but these products become synthesized again in the intestines. Its action in the bladder depends upon the reaction of the urine and on the length of the intervals between micturition. If the urine is retained for 6 to 7 hrs., a therapeutic effect may result even with slightly alk. urine. H. states in conclusion that F. Hinman (cf. C. A. 8, 181, 3204) was incorrect in the statement that neutral or feebly alk. urines are unable to split off HCHO, as Hinman failed to consider the temp. in testing for HCHO. This reaction is reversible at 37° .

L. W. RIGGS.

Influence of various sugars on action of the heart. K. MIZUNO. *Sei-I-Kwai Med. J.* 34, No. 3(1915); *J. Am. Med. Assoc.* 64, 1455.—A modification of Langendorff's and Wohlgemuth's irrigation app. was employed, and the sugar added to Ringer soln. The results of irrigating hearts of dogs and rabbits at body temp. and the heart of a tortoise at 15° , showed that fructose has the most favorable influence, lactose a similar but less favorable action often causing weakness and consequent stoppage, while cane sugar showed a stimulating and irritating action at first, which soon became arrhythmic and frequent with rapid weakening.

L. W. RIGGS.

Toxicity of trypsin and anaphylactic symptoms produced by it. F. ISHIWARA. *Sei-I-Kwai Med. J.* 34, No. 3(1915); *J. Am. Med. Assoc.* 64, 1455.—I. states that when trypsin in neutral or weakly alk. soln. is injected intravenously in guinea pigs the anaphylactic symptoms occur in about $\frac{2}{3}$ of the cases. This poisonous action does not appear to be due to the enzyme itself, as these actions remain strong after heating the prepn., which, as a rule, abolishes enzyme activity. The toxicity is attributed to the action of the diamino acid which is present in the strength of 91%. I. recommends intravenous injection as the best way of administering trypsin in studying its toxicity.

L. W. RIGGS.

The non-poisonous properties of manganese. TH. BOKORNY. *Chem. Ztg.* 38, 1290(1915); cf. C. A. 8, 1835.—In distinction to the other heavy metals, Mn is non-poisonous if it is in the form of its salts. When yeast was added to a 1% MnSO_4 soln. budding was observed although in a 3% or 5% soln. no action took place. No budding took place in similar solns. of Fe and Ni salts. Yeast steeped for 24 hrs. with MnSO_4 showed no test for Mn with the usual reagents after washing thoroughly; yeast similarly treated with solns. of FeSO_4 and CoSO_4 could not be washed free from the respective metals. The innocuous character of Mn salts is attributed to the fact that, unlike the other heavy metals, Mn does not combine chemically with the protoplasm.

R. L. SIBLEY.

Common salt as a poison for stock. F. R. GUTHRIE. *Agr. Gaz. N. S. Wales* 25, 663-4(1914); *Bull. Agr. Intelligence* 5, 1470.—The death of poultry and pigs has been traced to an excessive amt. of NaCl in the food. In a fowl which had died suddenly the contents of the crop weighed 50 g. and contd. 2.42 g. salt. In one case of poisoning of pigs the food supplied was a mixt. of pollard, barley meal, and 11.66% salt. The toxic effect of the salt appears to be due to its action on the muscles so that the animal becomes unable to walk and finally to stand. Death is caused by asphyxia, due to loss of power in the respiratory muscles.

Absorption and storage of digitalis substances in the heart. v. ISSKUTZ. Univ. Heidelberg. *Arch. exp. Path. Pharm.* 78, 155-87(1915).—The absorption of digitalis substances by the heart, because of the firm way they are bound, must be considered as a storage. This explains the long duration of the action of digitalis and the cumulative effects. C. J. WEST.

Experiments on rabbits after removal of the cerebrum. SUKETAKA MORITA. I. Behavior of the blood sugar concentration. *Arch. exp. Path. Pharm.* 78, 188-207 (1915).—Stimulations, such as venesection, constriction, diuretin, ether narcosis, painful irritation of the sensitive nerve elements, do not lead to hyperglucemia in rabbits after removal of their cerebrum. The increased blood sugar concn. produced in such animals is nearly of the same order as that in normal animals. Since in rabbits, which possess no cerebrum, "psychic" hyperglucemia can no longer be considered, it must follow that effects like terror and anger play only a secondary role in sugar mobilization. The point of attack of central stimulants which produce hyperglucemia, as diuretin, is probably not in the hemispheres but in the basal ganglia or in the mid-brain. II. The action of different poisons producing spasms. *Ibid* 208-217.—The action of cocaine-HCl differs in that the clonic muscular spasms and the complete stoppage of respiratory movements are lacking, while tonic cramps and intensive breathing are present. The tolerance for cocaine is considerably increased. Picrotoxin and phenol act as in the normal animal. Clonic muscular spasms in the case of camphor poisoning is connected with the presence of the cerebral hemispheres. Animals poisoned with KCN die more quickly than normal animals. Apomorphine has a cortical point of attack. III. Action of central stimulating agents upon chloral narcosis. *Ibid* 218-22.— β -Tetrahydronaphthylamine and ephedrin are capable of waking animals from a chloral narcosis produced by 0.05 g. per kg. body wt., thus indicating a sub-cortical point of attack. Cocaine and caffeine, contrary to the effect in normal animals, do not have this property. IV. Quantitative investigation of the sleep-producing action of chloral hydrate and urethan. *Ibid* 223-31.—Chloral hydrate and urethan have a more intensive action than upon normal animals. C. J. WEST.

The sugar-stimulating action of epinephrine-like substances. SUKETAKA MORITA. Univ. Vienna. *Arch. exp. Path. Pharm.* 78, 245-76(1915).—The effect of certain epinephrine-like substances upon the production of sugar by the liver after perfusion or subcutaneous injection has been studied. The following figures represent the active concn. in the frog liver (perfusion) expts., the active amt. per kg. rabbit body wt. in the subcutaneous injection expts. and the blood sugar: ethylaminoacetopyrocatechol, 1:1,000,000, 0.002, 0.166; monoethanolaminoacetopyrocatechol, 1:1,000,000, 0.002, 0.150; phenetidoethanolpyrocatechol, 1:500,000, 0.03, 0.187; dimethylaminoacetopyrocatechol, 1:200,000, 0.15, 0.267; diethylaminoacetopyrocatechol, 1:100,000, 0.15, 0.238; aminoacetopyrocatechol, 1:100,000, 0.15, 0.147; *p*-hydroxyphenylamine, ———, 0.15, 0.124; piperidoacetopyrocatechol was inactive. If ergotoxin is injected, the active concn. is much larger. A soln. of β -tetrahydronaphthylamine (1:10,000) does not cause the production of sugar, but if this is replaced by Ringer soln. sugar at once appears in the fluid. The effect disappears after 9 min. Subcutaneous injections of 0.15 g. per kg. does not produce glucosuria. C. J. WEST.

Pharmacological investigation of the vasomotor centers for the splanchnic vascular region of the frog. A. FRÖHLICH AND S. MORITA. Univ. Vienna. *Arch. exp. Path. Pharm.* 78, 277-316(1915).—A method is given which detcs. the action of vascular agents with a central point of attack upon the circulation of the splanchnic vascular region of the frog. Centrally vasoconstrictory are: strychnine, cocaine, β -tetrahydronaphthylamine, strophanthine digitalin, NH_4 , Et_2O and camphor vapor. Caffeine

is slightly vasoconstrictory. Amyl nitrate and heat are vasodilatory. Cocaine in high doses acts through paralysis. Antipyrine, CO₂ gas and *p*-hydroxyphenylethylamine were inactive.

C. J. WEST.

Theory of narcosis. J. TRAUBE. *Arch. ges. Physiol.* 160, 501-10(1915); cf. *C. A.* 7, 3795.—The 1st condition for the action of a narcotic is its small *solution tenacity* ("Haftdruck") towards H₂O. For the slightly volatile narcotics the surface activity towards air is an approximate measure of the soln. tenacity. The driving force of osmosis is the reciprocal soln. tenacity towards H₂O; the resistances are the frictions which oppose the diosmotic substances in the form of gel walls and viscous colloidal fluids. The quotient of 1/soln. tenacity × friction det. the osmotic velocity. The smaller the soln. tenacity towards H₂O and the greater, therefore, the narcotic properties, the greater is its capacity to dissolve or to swell gels (gelatin, Na cholate, protein) as well as to decrease the friction of the protoplasm. Narcotics have, therefore, the capacity to eliminate or to decrease the resistance due to friction which opposes their passage. Narcotics act as catalyzers, accelerating flocculation (lecithin, nucleoproteins), retarding oxidations and other ferment actions (yeast-, zymase- and invertase-action). Narcotics decrease the elec. processes in the nerves corresponding to their narcotic action. The knowledge that the narcotic action of narcotics goes parallel to the catalytic action upon the chem., physical and especially the elec. processes, has considerably increased our ideas of the method of narcosis. The special processes as related to narcosis are not yet known.

C. J. WEST.

Fate of papaverin in the animal organism. KURT ZAHN. Univ. Breslau. *Biochem. Z.* 68, 444-76(1915).—Papaverin may be pptd. quant. from a 2% soln. by adding NH₄OH. It is extd. from organ tissue by rubbing the organ to a paste, adding a little very dil. HCl, treating with 3-4 vols. alc., making ammoniacal, shaking, allowing to stand 1 day, filtering, washing the residue with alc. NH₄OH, evapg. to dryness, taking the residue up in b. H₂O, filtering and pptg. with NH₄OH. The pptn. is complete in from 1 to 4 days. An excess should be avoided as papaverin is sol. in NH₄OH. Papaverin mur., injected subcutaneously into rabbits, cats and dogs, was not found in the organs or the excretory products of the animals, as such, nor as oxidation, decompn. or rearrangement products such as the di-Me ether of protocatechuic acid (veratrumic acid), papaverinsulfonic acid or a glucuronic acid. No information could be obtained as to the organs concerned in the utilization of papaverin. The ratio of the total to the conjugated H₂SO₄ in the urine is the same after papaverin injection. The only variation from the normal is that the urine shows a slight capacity for reducing Fehling soln.; this is markedly increased after b. with dil. HCl. After oral administration of papaverin, in excess of the lethal dose, a large part of the drug may be isolated from the stomach and intestine. In rabbits a dose of 0.12 g. papaverin mur. per kg., given subcutaneously, has no noticeable effect. The 1st effects are noticed with a dose of 0.25 g. and lethal doses are yet higher. Intravenously, 0.1 g. produces disturbances of the respiration. Dogs and cats are much more sensitive: 0.06 g. per kg. produce marked symptoms, while 0.12 g. is lethal after a few hrs. Papaverinsulfonic acid is indifferent in its effect and after subcutaneous injections, 35% can be isolated from the excretory products.

C. J. WEST.

Distribution and fate of colloidal silver in the animal body. III. J. VOIGT. Göttingen. *Biochem. Z.* 68, 477-509(1915); cf. *C. A.* 8, 3473.—Rabbits were injected with from 25 to 528 mg. of a 0.60% nonisotonic collargol soln., either in the ear or jugular vein, the animal killed by bleeding after a given time and the various organs examined microscopically. Most of the Ag was found in the lungs, liver, spleen and kidney.

C. J. WEST.

Poisonous action of ninhydrin. OSCAR LOEW. *Biochem. Z.* 69, 111-5(1915).—Ninhydrin is a poison for different lower and higher forms of life (bacteria, algae, phanerogams, protozoa, mice, guinea pigs). An apparent exception in the case of molds may be explained by the difficulty of reaching the protoplasm of the cells. C. J. W.

I. ZOOLOGY.

R. A. GORTNER.

The life-cycle of Cladocera, with remarks on the physiology of growth and reproduction in Crustacea. G. SMITH. Oxford. *Proc. Roy. Soc. London (B)* 88, 418-35(1915).—By isolating the young *Daphnia* at birth and keeping them at 27°, they have been bred for 19 generations without the appearance of males or ephippial females. In parallel cultures, when the parents were kept more crowded and at a temp. of 10°-17°, 7% males and 10% ephippial females were produced. The crowding does not directly influence the supply of food but appears to act by the accumulation of excretory matter. The parthenogenetic females kept isolated at 27° grow and reproduce more rapidly than those crowded at 10-17°, and store up reserve material almost exclusively in the form of glycogen, while the crowded parents tend to store up fat, and are inhibited in their growth. Storage of fat as opposed to glycogen is especially characteristic of males and ephippial females; it is judged that the fat-storage induced experimentally in the crowded parthenogenetic females at 10-17° is causally connected with the production by them of the sexual forms. The habit of glycogen-storage leads to rapid growth and parthenogenesis (a form of discontinuous growth), while the habit of fat-storage leads to inhibition of growth, and sexual mode of reproduction. In the higher Crustacea the act of growth and moulting is accompanied by heaping up of glycogen in the liver storage-cells as opposed to fat, while in the period between moults fat-storage preponderates. Preponderant fat-storage in the liver is characteristic of female crabs maturing their ovaries and of crabs infected by *Sacculina*, and in both these cases growth is inhibited. Hence both in *Cladocera* and *Decapoda* growth, on the one hand, and sexual maturity on the other, are accompanied by a different type of reserve storage, which is also distinct in the case of the male and the female. This is the physiological fact at the root of the antagonism between growth and sex. Sexual reproduction is a reaction to conditions when continued growth is disadvantageous or impossible. Sexual differentiation is an economy or division of labor by which the female reproductive cell stores the material for development and thereby loses the power of division, while the male cell retains the power of division but relies on the female to supply the material for development.

A. T. CAMERON:

Nature and formation of the fertilization membrane of the echinoderm egg. J. F. McCLENDON. Minneapolis. *Intern. Z. physik. chem. Biol.* 1, 163-8(1914).—No fertilization membrane appears on the egg of a sea-urchin from which the mucous layer has been removed before fertilization even though the egg segments. No membrane comparable in toughness with the fertilization membrane exists on the unfertilized egg.

E. M. FRANKEL.

The "cerodocytes" or "oenocytes" of insects considered from the biochemical view point. A. CH. HOLLANDE. *Arch. anat. micr.* 16, 1-66; *Zentr. Biochem. Biophys.* 17, 409(1914).—Certain yellowish red cells, the so-called "oenocytes" or "cerodocytes" (named from their property of containing wax crystals), are present in almost all insects in the body cavity and region of the tracheae. These cells are not excretion cells; they never contain urates or oxalates and do not absorb pigments. The oenocytes are more closely related to the fat cells and bear a close functional relation to the nutrition of the insects. After a diet rich in fat or after injection of olive oil the oenocytes become loaded with granules which disappear during fast. The wax also

disappears from the cells during metamorphosis or deposition of eggs. Glycogen also occurs in the oenocytes and the latter are, furthermore, capable of storing H_2O . After injection of *intra vitam* staining dyes the latter are absorbed by the lipid granules of the oenocytes. Lipochromes ingested with the food are absorbed by the fat granules.

H. S. PAINE.

Catalases of the lower animals. RUDOLF ZIEGER. Univ. Leipzig. *Biochem. Z.* 69, 39-110(1915).—The catalase content of nearly all groups of animals except the protozoa was tested. No relation could be established between the mode of living, especially the intensity of the oxidation processes, and the catalase content. Neither respiration (air or water) nor food nor movement had a definite influence. That there is some relation between catalase content and metabolism follows from the facts given below. Those organs, which are specially active chemically, as the liver and kidneys, are characterized by a surprisingly large content of catalase. This is true of both vertebrate and invertebrate animals. The intestine showed a variable content, which seems to be dependent upon how far it performs the functions of the liver. The adipose tissue is very rich in catalase, especially in insects, where it must play a role in metabolism. In the lymph there is a well marked parallelism between the catalase content and the amt. of hemoglobin and the preformed constituents. It is shown that in winter, when life is not as active, the catalase content of the intestine of the echinoderms, lumbricus and snails is considerably lower than in summer. In the snail and the hedgehog there is a parallelism between the catalase and glycogen contents of the liver. Unripe eggs are very active, while the ripe eggs have only a slight catalytic power. Eggs rich in yolk, and the embryos of animals, show a marked activity during development without, however, ever reaching the characteristic values for the species. At the time of birth, when the organs assume their full functions, the catalase content increases rapidly to a max. and then decreases. The behavior of the catalase content during the post-embryonic development of insects was studied. As far as investigated, the kinetics of the reaction are expressed by the scheme of Steche and Waentig.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Note on vinegar. J. S. JAMIESON. *Analyst* 40, 106-7(1915).—The comp. is given of a vinegar prepd. from germinated maize and pasteurized, of the same vinegar before pasteurization, and of an ordinary barley malt vinegar. P. B. DUNBAR.

The use of colloidal iron in the determination of lactose in milk. REUBEN L. HILL. Cornell Univ. Med. College. *J. Biol. Chem.* 20, 175-7(1915).—Dil. a 10 g. sample of milk to 25 cc. and add about 3 cc. of 10% colloidal Fe soln.; the last portion of the Fe soln. is added drop by drop with thorough shaking. When pptn. is complete, a clear liquid seps. from the flocculent ppt. Filter into a 100 cc. volumetric flask and wash the ppt. with distd. H_2O until the flask contains about 100 cc. Dil. to the mark and det. the lactose by the Benedict method. About 16 cc. of the dild. sample will be required to reduce 25 cc. of the Benedict soln. The detn. is carried out in a wide-mouthed, 150 cc. Jena, flat-bottomed flask. Dissolve 3-4 g. anhydrous Na_2CO_3 in 25 cc. of Benedict soln. to which has been added 25 cc. H_2O and a little powdered pumice. Run in rapidly about 14 cc. of the lactose soln. and boil at least $1\frac{1}{2}$ min.; then add the last portions a drop at a time until the reduction is complete. When the end point is reached the liquid will have a yellowish tinge, to which the blue color returns very slowly; before reduction is complete the color is blue or greenish

and rapidly becomes bluer. 25 cc. of Benedict soln. are reduced by 0.0676 g. of anhyd. lactose. The method is quick, very accurate and can be used by the ordinary lab. student.

A. P. LOTHROP.

Further data regarding a method for detecting the watering of milk. RZIO COMANDUCCI. Naples. *Boll. chim. farm.* 53, 67-9(1914).—C. submits further data regarding his method (based on the polarization and lactose content) for detecting the watering of milk (*Boll. chim. farm.* 51, 109-10; cf. *C. A.* 6, 2471). Analysis of the milk of 50 cows in 15 dairies in the vicinity of Naples indicated that the manner of milking and the age and breed of the cows had a very slight influence on the polarization and lactose content of the milk, so that the addition of 10% or more of H_2O was readily detected. The mean rotation of the liquid obtained by heating unwatered milk with CCl_3CO_2H and filtering was $+2^\circ 47'$ (Laurent polariscope) in a 100 mm. tube at 15° and the limit of variation was small. Concordant results were obtained when the lactose content was calcd. from the rotation of the above soln. and from the reduction of Fehling soln. by a method described in the original publication mentioned above. C. discusses a criticism of his method by Corradi (*C. A.* 7, 660) to the effect that the limit of variation of the lactose content of unwatered cow milk is so great (3.5-5.5%) that the method will only serve for the detection of watering when relatively large amts. of H_2O have been added. C.'s data indicate that the normal limit of variation of the lactose content is considerably smaller (av. content = about 5.5%) than the above and that the uncertainty in the method arising from this cause does not extend to the detection of watering in cases where more than 10% of H_2O has been used.

H. S. PAINE.

The manufacture of condensed milk, milk powders, casein, etc. R. T. MOHAN. *J. Soc. Chem. Ind.* 34, 109-13(1915).—Discussion of methods of analysis. P. B. D.

Manufacture of cheese from "heated" milk. M. BENSON. *J. Bd. Agric.* 21, 878-89(1915); *J. Soc. Chem. Ind.* 34, 148; cf. *C. A.* 8, 1173.—To obtain a typical cheddar cheese from pasteurized milk, the pasteurizing temp. should not be higher than 88° when the milk is heated very rapidly, or 77° when the period of heating is from 15 to 30 mins. A blue-veined cheese of good quality was obtained when the milk was heated for about 15 mins. to $88-93^\circ$. Cheeses prepd. from heated milk contained: water 33.61-36.22, fat 32.36-34.53, insol. N (probably unaltered casein) 2.49-2.91%. In the case of very rapid heating, the number of organisms in the milk was not effectively reduced below 77° , but at this point the number was reduced to $1/10$ of the total and at $82^\circ C.$ to one $1/88$, while at 93° practically all the organisms were destroyed. There was a much greater reduction when the milk was maintained at 66° for 15 mins. than when it was heated very rapidly to 77° .

E. J. C.

The ripening of Neufchatel cheese. O. LAXA. Prague. *Z. Nahr.-Genussm.* 28, 387-92(1914).—The usual chem. exams. of cheese with a view to its ripening processes do not deal with the differences in comp. of the surface of the cheese, where the ripening begins, and the inner part. In work upon the ripening of different cheeses, Neufchatel cheese has heretofore been classed with Camembert or Brie. L. examd. 2 samples of Neufchatel cheese for H_2O , solids, fat, casein, albumoses and peptones, amino N, NH_3 , acids, and ash. The surface layers showed a further advance in ripening than the interior by the low casein content and a consequently higher amino and volatile acid content. The surface also contained the higher % of insol. ash due to the formation of insol. P_2O_5 , by the action of casein products upon the sol. P_2O_5 , drawn to the surface as the cheese dries out. Analogous analyses of Camembert and Brie cheeses were made. In these the ripening action is likewise from the surface inward. The bacteriol. exam. of Neufchatel cheese yielded results similar to those of Mazé (*Ann. inst. Pasteur* 24, 395-428, 435-466, 543-562(1910)).

L. D. ELLIOTT.

Organic phosphoric acid of wheat. (Preliminary note.) GEORGE CLARKE. *J. Chem. Soc.* 107, 360-1 (1915).—A white, amorphous substance of type $C_{12}H_{22}O_{14}P_{10}Ca_7Mg$ was obtained by extg. wheat with 0.2% HCl and treating as in the prepn. of phytin in mustard (*C. A.* 8, 1957). H. A. PIPER.

Faced pearl barley. J. F. LIVERSEGE AND H. HAWLEY. *J. Soc. Chem. Ind.* 34, 203-4 (1915).—Pearl barley is considered adulterated with mineral facing if the insol. ash content is over 0.1%. H. A. PIPER.

The food value of wood. G. HABERLANDT. *Sitzb. kgl. preuss. Akad.* 1915, 243-57.—H. discusses the possibility of using the starch, oil, and in some cases protein and glucose found as reserve substance in the storage tissues of sap-wood as a food for people and domestic animals. The woody character of the cell walls containing the reserve substance is indigestible and only by grinding into a fine meal, which breaks and disintegrates the cell walls can horses and cattle use wood as a feeding stuff.

H. A. LEPPEL.

Gossypol. A toxic substance in cottonseed. A preliminary note. W. A. WITHERS AND F. E. CARRUTH. *Science* 41, 324 (1915); cf. *C. A.* 6, 2474.—W. and C. have sep'd. from cottonseed kernels a toxic substance which appears to be identical with a substance which Marchlewski (*J. für prakt. Chem.* 60, 80 (1899)) sep'd. from crude cottonseed oil and called gossypol. This substance is quickly oxidized in alc. NaOH. Its oxidation renders it non-toxic, and thus diminishes if it does not entirely remove the toxic properties of cottonseed meal. P. B. DUNBAR.

Utilization of the stalks and leaves of sweet potato plants (*Ipomoea batatas* Lam.) as feed material. T. KATAYAMA. *B. Agr. Japan* 2, 41-74; through *Chem. Zentr.* 1914, II, 731.—Sweet potato tops were used as provender. Fresh stalks like turnip tops are not suited for exclusive feeding. They are best fed together with a plentiful quantity of rough provender. Loss of nutritive matter during fermentation is considerable and a very useful food may be obtained. W. H. FAY.

Toxic products in food and their detection (HIGGINS) 11B. The constitution of milk (LINDET) 11F.

U. S., 1,136,881, Apr. 20. F. D. LARABEE. Wheat flour is subjected to a rubbing action between rolls or disks to break down the starch cells of the flour without materially affecting its granulation.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

The amount of lead, copper and zinc in artificial mineral waters, and the determination of these metals. C. REESE and J. DROST. Schleswig-Holstein. *Z. Nahr.-Genussm.* 28, 427-49(1914).—The products of 100 machines for mfg. artificial mineral water were examd. for Pb, Cu and Zn and it was found in the case of Pb that 21 machines delivered water with more than 0.35 mg. per l., 13 with more than 0.6 mg. per l. and 9 with more than 1 mg. per l. Cu was found over 0.35 mg. per l. in 48-9% of the machines, over 0.6 mg. in 21%, and over 1 mg. in 9%. Zn was not detd. as it was found only in traces. The samples were drawn after standing for 12 hrs. under the highest pressure the machines could stand. The Cu and Pb were pptd. as sulfides, sepd., made up to definite vol., and independently detd. by colorimetric comparison of their respective sulfides with known standards. This result was then checked in the case of the Pb by pptg. it in another aliquot as the chromate and comparing the resultant opalescence with a standard PbCrO_4 prepd. at the same time. The Cu was detd. by comparing its ferrocyanide with a standard. A further check was made in the original water by running a colorimetric detn. of both metals pptd. together as sulfides. Full directions for purifying chemicals used and for precautions to be taken are given. The authors claim to be able to recognize as little as 0.01 mg. per l. of either Pb or Cu and to det. accurately 0.10 mg. Zn was detected by pptg. with $\text{K}_4\text{Fe}(\text{CN})_6$. H. L. LOURIE.

Water analysis. (Free chlorine, manganese and phosphorus.) L. W. WINKLER. *Z. angew. Chem.* 28, 1, 22-3(1915).—Detection of HOCl or free Cl in water: To 250 cc. of the water to be examd. and also to an equal quantity of H_2O (blank), add 1 to 2 drops of dil. methyl orange indicator (1 to 5000) and 2 to 3 cc. of 10% HCl . If the water contains HOCl , the color disappears, while the blank remains a rose-red. As little as 0.1 mg. of Cl per l. can be detected. The method is still more sensitive when methyl red is employed (0.01 g. is dissolved in 1 cc. 0.1 N NaOH and made up to 100 cc. with H_2O). One drop in 500 cc. of the water to be examd. permits the detection of 0.02 mg. free Cl. Quant. detn. of Cl.: To 100 cc. water add 0.2 g. KI , 1 cc. starch soln. and 2 to 3 cc. 25% H_3PO_4 . The liberated I is titrated with 0.02 N $\text{Na}_2\text{S}_2\text{O}_3$. The method can also be employed in modified form for the rapid detection of small quantities of Mn in water. To 2 portions of 250 cc. of the water add one drop of methyl orange; to the first portion add 1 to 2 cc. 10% NaOH . After a few min. add 5 cc. of a 10% HCl soln. to both. If Mn is present, decolorization takes place in the first portion after 1 to 2 min. As little as 0.1 mg. of Mn per l. can be detected. The presence of Fe does not interfere, but nitrites and much organic matter diminishes the sensitiveness of the reaction considerably. In the presence of H_2S , the method is unreliable. For the detection of phosphoric acid in water, employ the following method: To 1000 cc. of the water, add 1 cc. of 10% FeCl_3 soln. and 2 cc. of a 10% alum soln. Heat on the water bath for 1 hr. The Fe salt of the H_3PO_4 ppts. Filter through cotton and dissolve the ppt. in HNO_3 . To the soln. add 1 drop of HCl and evap. over the steam bath. Dissolve the residue in a few drops of HNO_3 and water, filter again, and conc. to 5 cc. Add 5 cc. molybdate reagent, as commonly employed. A yellow ppt. indicates P_2O_5 . A colorimetric method for the quant. detn. of the P_2O_5 is also given. A. LEDERER.

The Blacher potassium palmitate method for the determination of hardness in water. W. PFLANZ. *Intern. Z. Wasser-Versorgung* 1, 253-4(1914).—This method consists in titrating the sample of H_2O with 0.1 N K palmitate soln. with phenolphthalein as an indicator. To adapt Blacher's method to the needs of men who are not chemists, P. makes a slight change by substituting methyl orange for dimethylaminoazobenzene. Results are given in terms of German degrees which show that the total hardness as detd. by this method varies from the theoretical by 0.1-0.3°.

FRED W. TANNER.

New methods of bacterial water analysis. E. HESSE. Berlin. *Intern. Z. Wasser-Versorgung* 1, 69-73(1914).—H. reviews the literature covering many different methods proposed recently.

FRED W. TANNER.

Detection of specific bacteria in water. A. MÜLLER. *Arb. kais. Gesundh.* 47, 513-26(1914).—M. uses Omelianski's gypsum blocks to det. the permeability of soil to bacteria with *B. prodigiosus* as the indicator (cf. *Centr. Bakt. Parasitenk., Abt. II* 5, 652(1899)). Gypsum blocks were prepd. by making a thin mixt. of extra quality sifted gypsum. One g. of sifted $MgCO_3$ and 100 cc. of hot, boiled, distd. H_2O are added and thoroughly mixed in a casserole. Then 0.8 cc. of a 5% cabinet-makers' "binder" are added and the mixt. put into a special circular mold. The size and thickness of the plates will vary with the amt. of H_2O to be examd. A plate 8 cm. in diam. and about 1.2 cm. thick will take up 20-25 cc. H_2O . The plates set rapidly and may be dried after removing from the mold. They may be used in Petri dishes. To use the plates, the water is poured evenly over the surface and sufficient amt. of conc. peptone bouillon added to give a mixt. of bouillon and H_2O equal to a normal bouillon. After 60 to 70 hrs., the prodigious colonies are apparent from their red pigment. By pouring agar over the plate, the other bacteria in the water may be detected. To enumerate *B. coli* in H_2O , lactose and fuchsin are added to the conc. bouillon mentioned above. After incubation, *B. coli* colonies appear as red spots similar to those on Endo's medium. In cases where it is necessary to filter large quantities of H_2O , M. has made use of the Büchner funnel. Gypsum plates of the proper size are fitted by a rubber ring to the top of a Büchner funnel. Suction is applied.

FRED W. TANNER.

Special water standard. W. F. MONFORT. *J. Am. W. W. Assoc.* 2, 65-73(1915).—The Treasury Department has adopted a bacteriological standard for drinking waters supplied by common carriers in Interstate Commerce limiting the agar count to 100 per cc. for 24 hrs. at 37° and recommending that not more than one out of five 10 cc. portions of any sample examd. show the presence of the *B. coli* group. The report (*Reprint* No. 232, Public Health Reports) is printed in full.

D. K. FRENCH.

The decrease in the typhoid death rate in the United States by filtration of drinking water. E. IMBRAUX. *Intern. Z. Wasser-Versorgung* 1, 117-8(1914).—I. proves by statistics that filtration has caused a decrease of from 50 to 75% in the typhoid death-rate in representative American cities. Attention is called to the fact that ozone is being used by about 20 German cities to sterilize their water, while none in the U. S. are using this process.

FRED W. TANNER.

Do fish as bacillus carriers affect the quality of water courses? P. T. MÜLLER. *Intern. Z. Wasser-Versorgung* 1, 148-51(1914).—The presence of fish in a water course is of epidemiological interest only when they come from infected water. They may then introduce pathogenic bacteria which may give rise to sickness among the consumers.

FRED W. TANNER.

The hot spring near Krozingen (Baden). G. RUPP. Karlsruhe. *Z. Nahr.-Genussm.* 28, 425-6(1914).—A hot spring was found near Krozingen which yields daily 7,000,000 l. of water containing in soln. about 2500 kg. CO_2 . The water has a

temp. of 40.3° , sp. gr. (15°) 1.00426, solids dried at 180° 4.0158 g. per kg. The gas consists of 94.6% CO_2 and 5.4% of N. Analyses of the water are given. H. L. L.

Studies on the self-purification of streams. E. B. PHELPS. *Public Health Repts.* 29, 2128-32(1914).—The reactions involved are biochem., 3 factors being necessary: org. matter, O and oxidizing bacteria. Org. matter and oxidizing bacteria are always present. As O_2 is used up re-aeration occurs, the intensity being a direct function of the lowering of O content. Re-aeration is increased by agitation, a fact of greatest importance in self-purification of rivers. Opposed to re-aeration is the using up of O_2 by org. matter. The latter is well known to be a monomol. reaction from which the conc. of pollution may be detd. Re-aeration is being studied in order to work out with more assurance the general principles which underlie the self-purification of streams.

FRED W. TANNER.

Examination of water on railway trains. E. BARTOW. *J. Am. W. W. Assoc.* 2, 74-82(1915).—100 samples of water were analyzed from cars coming from all parts of the country. Bacteriological and chem. exams. were made and the methods used are given in full or with reference. 53% of the waters examd. would not pass government specifications. The better water was found on sleeping cars and parlor cars, the poorer on coaches and smoking cars.

D. K. FRENCH.

Dry feed of chemicals in water purification. W. F. MONFORT. *J. Am. W. W. Assoc.* 2, 200-5(1915).—Dry feed for alum, lime and Fe sulfate offers many advantages in reduction of pipes and fittings exposed to corrosion, economy of space, economy of attendance and ready control of chemicals. Some difficulty has attended the use of this system for Ca hypochlorite. Many devices for feeding are described.

D. K. FRENCH.

Hypochlorite treatment of water supplies. H. A. WHITTAKER. *Pub. Health Repts.* 30, 608-18(1915).—A description accompanied with drawings, of a portable plant together with full equipment necessary for its proper administration. W. F. L.

The disinfection of water by hypochlorite. K. IMHOFF. *Intern. Z. Wasserversorgung* 1, 207-8, 222-4(1914).—A brief history of the use of hypochlorite in water treatment and a general discussion of the prep. and application of hypochlorite to water. The addition of hypochlorite in excess of $1\frac{1}{2}$ p. p. m. of available Cl will cause tastes.

F. W. TANNER.

Hypochlorite treatment at Ludington, Mich. GEORGE W. CLARK. *Munic. J.* 38, 394(1915).—An automatic device actuated by the water works pumps feeds 7 lb. per mil. gal. dry $\text{Ca}(\text{OCl})_2$. Cost of app. was \$257. Typhoid was markedly reduced.

LANGDON PEARSE.

Liquid chlorine sterilization of the water supply of St. Catherines, Ontario. A. MILNE. *Eng. Contr.* 43, 188-90(1915); *Can. Eng.* 28, 389-90(1915).—The water supply derived from the Welland Canal is treated with liquid Cl, the av. being 1.65 lb. with max. 3 lb. Cl per mil. imp. gal. The dosing is automatically controlled by a Venturi meter.

LANGDON PEARSE.

Use of ozone as a sterilizing agent for water purification. S. T. POWELL. *J. N. Eng. Water Works Assoc.* 29, 87-93(1915); cf. *C. A.* 8, 3336; 9, 341.—The ozonizers of the Baltimore County Electric Co. have been so modified that efficient results have been obtained. Organic colors, either in soln. or in colloidal condition, and odors have been eliminated; bacteria have been satisfactorily removed without the addition of objectionable chemicals and without leaving any detrimental after-effects from the treatment. The cost of the operation is estd. at \$2.50 to \$4 per mil. gals. The process should be found efficient and economical provided due consideration is given to the adaptability of the method for each particular supply.

E. BARTOW.

Rapid filter plant at Evanston, Illinois. L. PEARSE. *J. Am. W. W. Assoc.* 2, 160-80(1915); cf. *C. A.* 8, 1318.—Many of the bolts used to hold the strainer plates in place broke. These were replaced by monel metal bolts. During the summer the filter runs were exceedingly short, due to the presence of diatoms (*Asterionella*); in November the difficulty disappeared. Bacterial removal has been satisfactory but it has been deemed desirable to use about 3 lbs. of $\text{Ca}(\text{OCl})_2$ as a finishing agent.

E. BARTOW.

Baltimore water filtration plant. *Munic. J.* 38, 537-41(1915).—An engineering description of a rapid filter handling 120 mil. gal. per day, costing about \$1,750,000.

Omaha water chemist increases efficiency of (filter) alum. ANDREW JACOBSON. *Eng. Record* 71, 394(1915).—The process depends on the reaction between a soln. of $\text{Al}_2(\text{SO}_4)_3$ and scrap iron. A basic Al sulfate and FeSO_4 are formed. Consistent results have been obtained on the Omaha water supply when $\frac{1}{2}$ the former amts. of chemical are used.

FRANK BACHMANN.

Temporary water aerator at the Kensico reservoir. W. F. SMITH. *Eng. News* 73, 768(1915).

LANGDON PEARSE.

Data on coppering a reservoir at Hartford, Conn. 60th Report Bd. Water Commrs., Hartford, Conn.; *Eng. Contr.* 43, 277(1915).—In 1913 heavy algae growths were treated with 1 part CuSO_4 to 3.36 million parts H_2O , with a reduction of microscopic organisms of 99.6% in 5 days, and 30% in 2 days in two different reservoirs.

L. PEARSE.

European water purification and sewage disposal plants. E. BARTOW. *J. Am. W. W. Assoc.* 2, 13-24(1915).—Hamburg, probably the only continental city using a coagulant, uses alum prior to sedimentation for water purification and disposes sewage by diln. Bergedorf with no water available for diln. uses Imhoff tanks and sprinkling filters followed by fish ponds. This method is also used at Strassburg where satisfactory results with a diln. of 2 to 3 parts pure water are claimed. Methods of Fe removal at Berlin are described. Special attention is called to Reinsch screens and also the disposal of sewage on sewage farms with comment on the types of crops obtained from such farms. The Lab. of Water Hygiene is given attention. At Dresden the Mn content has caused considerable trouble and 2 Mn removal plants, one using Mn-removing algae, the other Mn permutit, are proving satisfactory. The first method is considered the more economical and satisfactory. At Coethen 92% suspended matter is sepd. by sedimentation; the sludge is removed before putrefaction starts and the effluent passes to sprinkling filters. Magdeburg has the only large plant using Puech-Chabal filters. The method is satisfactory but expensive. At Munich, diln. in the Isar River is sufficient. England: Softening by lime, soda and permutit at Bradford is described; also the largest municipal permutit water softening plant at Hooten near Liverpool. Expts. in aeration with the use of activated sludge in process at Manchester, which work is also being carried out by the Water Survey Sta. at the Univ. of Illinois, are referred to.

D. K. FRENCH.

Magdeburg tap water. O. WENDEL. *Z. angew. Chem.* 28, I, 91-2(1915).—The sanitary analyses and plankton content of the tap water for 1914 with comparative

figures also for 1912 and 1913 are given. The K content in 1914 was somewhat lower, on account of the restriction of the potash industry during the war. The quality of the water is good.

ARTHUR LEDERER.

Paris solves war-time water supply problems. F. M. WELDON. *Eng. Record* 71, 279(1915).—Burial of dead on a watershed forced suspension of Dhuis supply. Seine river water was filtered and sterilized in emergency.

FRANK BACHMANN.

Sewage treatment experiments with aeration and activated sludge. EDWARD BARTOW AND F. W. MOHLMAN. *J. Ind. Eng. Chem.* 7, 318-20(1915); *Eng. News* 73, 647-8(1915); *Munic. J.* 38, 504-5, 509(1915); *Eng. Contr.* 43, 310-1(1915); *Eng. Record* 71, 421-2(1915).—On fresh sewage of domestic origin, nitrate was formed in 15 days by blowing 4830 cu. ft. air. By syphoning off supernatant liquid and refilling, sludge was accumulated. On the 31st treatment, 3 cu. ft. air per gal. sewage were required in 5 hr. Nitrification is complete. One hr. aeration seemed practically sufficient. Worm life was active (*Aeolosoma hemprichi*). The sludge contained (% on dry basis) 6.3 N, 4 fat, 1.44 P, and 75 % volatile matter.

LANGDON PEARSE.

Coöperation sought in conducting activated sludge experiments at Baltimore. LESLIE C. FRANK AND CALVIN W. HENDRICK. *Eng. Record* 71, 521-2(1915).—Discussion of design and operation of continuous flow aero tanks is accompanied by request for suggestions and criticisms.

FRANK BACHMANN.

Sewage aeration at Lawrence and Manchester compared. H. W. CLARK. *Eng. Record* 71, 367-8(1915).—C. states that the heavy, brownish gray, gelatinous and other growths upon the slate beds at Lawrence which clarify the circulating sewage are probably the same bodies as those developed by Fowler and Ardern and Lockett in the Manchester tank and called "activated sludge."

FRANK BACHMANN.

Sewage disinfection for vessels and railway coaches. L. C. FRANK. *Public Health Reports* 30, 9-15(1915).—The app. consists of a tight insulated tank having influent and siphon effluent pipes for the sewage and influent live steam pipe. The steam pipe is fitted with a valve operated by a float which turns on steam when tank is nearly full. Steam pressure after the contents of the box are heated forces the material through the outlet siphon. Bacterially the efficiency is 100%. The app. will cost about \$15-20 per coach. The cost of operation per tank per coach per day is about 11½ cents.

J. GAUB.

Chemical disinfection of excreta. WILLIAM DREYFUS. *Am. J. Public Health* 5, 59-63(1915).—Excreta collected in a tank containing 3 inches of water to which is added 2% of a germicide especially adapted to the purpose and having a phenol coefficient of 9 to 10, was satisfactorily disinfected. Good results were obtained whether the material was mixed or allowed to remain quiescent. The fluid contents of the tank could have been disposed of at any time in any manner esthetically acceptable and would not possibly become a menace to health. Similar expts. using 1% and 2% solns. of formalin did not give satisfactory results.

E. BARTOW.

Ninth report Royal Commission on Sewage Disposal. ANON. *Can. Eng.* 28, 484, 491(1915); *Eng. News* 73, 785(1915).—A concise summary of earlier reports, dealing also with the discharge of manufacturing wastes which may not be taken into sewers, and with the disposal of domestic sewage and refuse in rural areas. Standards are prescribed for industrial wastes based (1) on the max. allowable suspended matter, and (2) on the dissolved O absorbed. The wastes are classified by content of suspended matter, dissolved impurities, and by practicability of treatment. Certain waste liquors can be partly purified by clarification. Evapn. may be necessary. Additional standards of hardness, causticity, acidity, arsenic, oil films, etc., are suggested.

L. P.

Maintenance of sewers and disposal works demands treatment of injurious trade wastes. W. L. STEVENSON. *Eng. Record* 71, 256-60(1915).—Damages to sewerage system justify the exclusion of harmful liquids produced by industrial plants. A digest of American and European regulations and a table showing substances excluded from sewer systems in American and Canadian cities are given. FRANK BACHMANN.

Detecting gasoline in sewers. A. D. LITTLE. *Munic. J.* 38, 476(1915); *Eng. Record* 71, 457-8(1915).—The app. consists of a long rubber sampling tube and aspirator, connected to the inlet cock of a priming spark plug, over which is slipped a collapsed rubber balloon. The balloon is inflated, and a spark made at the plug terminals. If gasoline vapor is present, from 1.1% up, an explosion occurs. LANGDON PEARSE.

Multiple-flow chambers in Imhoff tanks. JOHN H. GREGORY. *Eng. Record* 71, 433-4(1915).—An engineering discussion. FRANK BACHMANN.

Factors in design of Imhoff tanks at Fitchburg (Mass.). DAVID A. HARTWELL. *Eng. Record* 71, 332-3(1915).—There are five Imhoff tanks/ rectangular in plan, each measuring 30 X 90 ft., with a bottom in the form of 3 V-shaped depressions. The depth of the sewage in the tanks is 24 ft. 5 in. The tanks were designed to treat the sewage flow in 1930. The sludge digestion compartment of each tank was designed to store the sludge for a period of 6 mos. on the basis of a production of 7 cu. ft. of sludge per day for each 1000 persons. The sedimentation compartment provides for a detention period of from 7.3 hrs. for 3 mil. gal. to 1.6 hrs. for 14 mil. gal. The velocity of flow through the tank would be 16.3 ft. per hr. with a rate of 4 mil. gal. and 57 ft. per hr. with 14 mil. gal. FRANK BACHMANN.

Imhoff sewage tank at Manchester, England. O. J. WILKINSON. *Eng. News* 73, 770-1(1915).—A plant to handle 900,000 gal. per 24 hrs. of domestic sewage is described. LANGDON PEARSE.

Three districts for disposal of Cleveland's sewage. R. W. PRATT. *Eng. Record* 71, 422-3(1915); cf. *C. A.* 9, 113.—It is the intention to have three sewage districts: the southerly, westerly and easterly. The westerly district will have treatment works consisting of grit chambers, fine mesh screens, disinfection app. and the discharge of the sewage through submerged outlet into the lake. The sewage from the easterly district will be treated in grit chambers and sedimentation tanks and disinfected. The southerly district's treatment involves grit chambers, sedimentation tanks and sprinkling filters. FRANK BACHMANN.

Design, cost and operation of new sewage treatment plant at state hospital, Warren, Pa. P. E. MEBUS AND F. R. BERLIN. *Eng. Contr.* 43, 265-8(1915).—Electrically driven pumps force the sewage to the plant, which contains Imhoff tank, dosing chamber, sprinkling filter (0.22 acre, 7.5 ft. deep), chemical house, secondary tank and sludge beds. The effluent of the filter is disinfected with $\text{Ca}(\text{OCl})_2$, reducing the bact. content to 9 to 72 per cc. The cost was \$37,855.90 for sewerage and treatment works to care for a population of 1800 with a flow of 150 gal. per capita. LANGDON PEARSE.

Low river flow exacting for Columbus sewage works. C. B. HOOVER. *Annual Report* 1914; *Eng. Record* 71, 492(1915).—Tank treatment reduced the suspended matter 60% and the dissolved O demand 25%. The purifying agencies in the filter beds were more active than in previous years. The present septic tanks are to be converted into Imhoff tanks. A table giving the analytical summary of the Columbus sewage treatment works is given. FRANK BACHMANN.

Schenectady's sewage disposal plant. *Munic. J.* 38, 499-504(1915).—An engineering description of a plant handling 8 mil. gal. daily with grit chamber, Imhoff tank and sprinkling filters, with sludge bed. LANGDON PEARSE.

Decatur (Illinois) installs plant for sewage tests. LANGDON PEARSE AND S. A. GREKLEY. *Eng. Record* 71, 495-6(1915).—A small expt. station was built to investigate possibilities of treating sewage containing corn products and gas works waste. It consists of coarse bar screens and grit chambers, an Imhoff tank, a sprinkling filter and secondary settling basin.
FRANK BACHMANN.

Processes available for the treatment of industrial wastes. LANGDON PEARSE. *Proc. Ind. Water Supply and San. Assoc.* 1915; *Eng. Contr.* 43, 363-5(1915).—A review of the status of the treatment of industrial wastes. The wastes are classified, and the procedure for taking up a problem indicated. The methods available are discussed: screening, settling, chem. pptn., septic tanks, filtration and evapn., with their application to packing houses, tanneries, etc. The sludge problem is important, as sludge may run as high as 100 cu. yds. to the mil. gal., with no assumed value. The O demand may be high, 900 to 1300 p. p. m. on mixed packing-house waste, with 20% consumed in first 24 hrs.; 400 to 1000 p. p. m. on tanneries, with 7% demand in first 24 hrs. Domestic sewage at 39th St. had O demand 100 to 125 p. p. m. with 25 to 30% in first 24 hrs., all at 20°. Care in design of works is recommended to produce efficient results at low operating cost. The treatment of sep. or mixed wastes is one of expediency, mixed wastes frequently being easier to handle.

LANGDON PEARSE.

All steel refuse incinerator, Roanoke, Va. J. C. WOODMAN. *Eng. News* 73, 678-89(1915).—This incinerator has a 50 ton capacity for a town having a population of 45,000. The furnace holds 16 cu. yds. refuse. The cost of the plant was \$41,350. The cost of operation ran from 30.6 to 44.3 cents on 3 test runs, the av. being 39 cents per ton over 16 days. Record of test is given.

LANGDON PEARSE.

Third report of the committee on standard methods for the examination of air. *Am. J. Pub. Health* 5, 250-4(1915).—The principal detns. are (1) temp. and humidity, (2) dust, (3) CO₂, (4) bacteria, (5) poisonous gases and metals. A recording psychrometer, in which the expansion of an inert gas in wet and dry bulbs is transmitted through tubes to a recording clock dial of the usual type, is satisfactory. The sugar filtration method for the detn. of dust is reasonably satisfactory. The modified Petterson-Palmquist is an entirely satisfactory method for CO₂ detns. The detn. of mouth streptococci is important. Tests for CO, CH₃OH, SO₂, CH₃(CH₂)₃CH₂OH, CH₃CO₂C₂H₅ and other poisonous fumes should be standardized.

J. GAUB.

Cyanide fumigation of ships. N. ROBERTS. *Pub. Health Reports* 29, 3321-5 (1914).—Two methods are described, both depending on the reaction $\text{KCN} + \text{H}_2\text{SO}_4 = \text{HCN} + \text{KHSO}_4$ for the HCN. Usually 1 oz. is used for 100 cu. ft. with 1 1/2 oz. H₂SO₄ and 3 fluid oz. of H₂O. HCN vapor when mixed with air in proportion of about 0.4% kills rats, vermin, etc., and some bacteria. It is efficient in plague prevention. Compared with SO₂ and CO, HCN is more advantageous in that no fire and no elaborate app. are required.

U. S., 1,135,684, Apr. 13. T. R. GREENHORNE. Removing boiler scale. See Brit., 17,462, 1913 (C. A. 9, 345).

U. S., 1,135,753, Apr. 13. A. H. BALDWIN. Apparatus for filtering water.

Brit., 28,537, Dec. 10, 1913. O. SÖDERLUND and T. BOBERG and TECHNO-CHEMICAL LABORATORIES, LTD. In distilling water from sea-water and other dil. solns. in film evaporators heated by the steam evolved from the soln., the steam being only slightly compressed, as described in 12,462, 1911 (C. A. 6, 3039), the evapn. is interrupted before undue rise in b. p. or scaling has occurred, and the residual liquid and the distillate are used for preheating the sea-water, etc. For this purpose, there may be used 2 evaporators or sections of an evaporator and 2 preheaters, 1 heating the feed for 1 evaporator by means of the residual liquid from both evaporators, and the other feeding the other evaporator with liquid preheated by the condensate from both evaporators.

15. SOILS AND FERTILIZERS.

M. X. SULLIVAN.

Osmosis in soils. C. J. LYNDE and J. V. DUPRÉ. Macdonald Coll., Que. *Trans. Roy. Soc. Can.* 8, Sect. III, 133-8(1914); cf. C. A. 8, 3477, 3610.—Using a conc. soil soln. as soln. and a column of soil approx. 2.5 inches deep as semi-permeable membrane an osmotic pressure was obtained equal to the pressure exerted by a column of H₂O 11.5 ft. high. The pressures observed are not due to the swelling of the soil column, but to osmosis; the semi-permeable membrane employed resembles ordinary semi-permeable membranes, since it is probably colloidal, and it absorbs H₂O more readily than it does a soil soln.

C. F. MILLER.

Availability of the nitrogen in Pacific Coast kelps. G. R. STEWART. *J. Agr. Res.* 4, 21-38(1915).—In prepg. dried and ground kelp as a fertilizer the availability or readiness with which the N in it changed to NH₃ and nitrates in fresh field soil was found to vary with different species and with the manner of prepn. The N of *Nereocystis luetkeana* is relatively very available while that of *Pelagophycus porra* is less readily changed. These 2 varieties are of minor commercial importance. *Macrocystis pyrifera*, the commercial variety, is very slowly changed in the soil. The availability of the N of *M. pyrifera* is greatest when the kelp is added in a fresh or only partially dried condition. When fully dried the availability of the N decreases materially. Removing a large portion of the salts from either fresh or dry *Macrocystis* by leaching does not cause it to decomp. more readily. To grind readily *Macrocystis* must be dried until crisp, but should not be heated more than necessary and should not be scorched or overheated. The addition of moderate quantities of *Nereocystis* to a sample of fresh soil in the lab. did not interfere with either ammonification or nitrification of readily available organic matter such as dried blood. Similar expts. with *Macrocystis* showed at first a decrease in the rate of transformation especially in nitrification. Later the ammonification and nitrification became practically normal. When kelp is used in field practice, it is probable that neither ammonification nor nitrification would be interfered with by kelp or the salts in it.

M. X. S.

Organic constituents of Pacific Coast kelps. D. R. HOAGLAND. *J. Agr. Res.* 4, 39-58(1915).—After a brief résumé of the literature the general comp. of the principal species of Pacific Coast kelps is discussed. An extended series of analyses is presented with exptl. data concerning the nature of algin and other carbohydrate compds. present. The forms of N in the kelp are considered. Much of the N is in a non-protein form. Expts. are reported on the form of the I; only a small proportion of it is believed to be organically combined. The high content of organic S in the kelp is noted and a table of analyses is given. The economic phases are discussed with reference to feeding value and utilization of organic by-products. The results indicate only slight possibility of commercial value in these directions. Comparative lab. expts. on the destructive distn. of kelp, oak sawdust, and Douglas fir shavings were made and the conclusion is reached that kelp distillates are of no practical importance. M. X. S.

Influence of manganese upon the nitrifying bacteria of leguminous plants. M. D. OLARU. *Compt. rend.* 160, 280-3(1915); *J. Soc. Chem. Ind.* 34, 294.—Nitrifying bacteria from the root nodules of leguminous plants were cultivated in a sterilized broth prep'd. from haricot beans with the addition of 2% sucrose. To 100 cc. of this medium 0.01-1.0 mg. $MnSO_4$ was added and after keeping at 19° for 48 hrs. the gain of N was det'd. The max. increase (75.5%) was obtained when 0.5 mg. Mn was added, the control showing a gain of 3.5%. Other expts. with a slightly weaker broth, containing less initial N and extending over 50 and 114 days showed that the optimum quantity of Mn was 2.0 mg. in each case and the % gain of N 38.4 and 31.2, resp. The controls gave 8.8 and 5.6% gain in N. M. X. S.

Fertilizer value of sodium chloride. II. H. G. SÖDERBAUM. *Kgl. Landbruks Akad. Handlingar Tidskrift* 54, 19-29(1915); cf. *Ibid* 1912, 21-9; *C. A.* 8, 1183.—The conclusion that this salt under certain circumstances assumes the role of KCl in fertilizing rests upon the assumption that the latter does not, as has been hitherto considered, function through its K content but by some other property in common with the NaCl. The property in common may lie in the Cl or in a "general salt influence." The "general salt influence" may be defined as the power to dissociate into a certain amount of positive and negative ions which, without serving as direct nutrients, nevertheless satisfy certain other physiological needs which are as yet unexplained. The effect on the yield of grain varied from -3 to +13% after the addition of NaCl. When added to $NaNO_3$ the total crop increased 16%; to NH_4Cl , 3%; and to $(NH_4)_2SO_4$, 29%. S. does not recommend as yet the substitution of KCl by NaCl in general practice. A. R. ROSE.

The utilization of the nitrogen and organic matter in septic and Imhoff tank sludges. C. B. LIPMAN AND P. S. BURGESS. Univ. Calif. Agr. Expt. Sta., *Bull.* 251(1915).—Septic and Imhoff tank sludges contain from 1.23 to 2.66% of N and from 0.77 to 1.82% of P_2O_5 . The com. value would not exceed \$10 per ton of dry material. The actual value would depend upon the available N present. A new method is suggested for detg. available N. It is transformed from organic N to nitrate N by means of the soil itself. Not only do the different sludges behave differently in any one soil but different soils have a different action on the various sludges and also on common com. N carriers. Sludge should furnish valuable fertilizers but should be used either alone or in combination with superphosphates or K salts in accordance with the needs of the various soils. E. BARTOW.

Road sweepings as manure. *J. Board Agr.* 21, 733(1914); *Exp. Sta. Rec.* 32, 219.—A chem. analysis of road sweepings is given; it shows that they contain about the same constituents as an ordinary soil. J. J. S.

Review of recent work on anticryptogams and insecticides. G. TOMMASI. Rome. *Ann. chim. applicata* 3, 111-46(1915).—Topics reviewed are: Cu salts, $FeSO_4$, HCHO,

S, polysulfides, lime-S mixts., CS_2 , soap, petroleum, "carbolineum" phenols, nicotine, As preps. and HCN. S. LEVY.

ROBERT WAHL.

Acidic energy of wines. C. MENSIO AND E. GARINO. *Ann. R. accad. agricoltura Torino* 56, 138(1914); through *Ann. chim. applicata* 3, 148.—The values obtained by inversion of sucrose at $+76^\circ$, are not always comparable to those given by catalysis with ethyl diazoacetate, but the causes for these differences are unknown. Using the values obtained by inversion of sucrose as being more const., it has been found that the acidic energy of the wines examd. varies between very wide limits, about equal to the energy possessed by 1/1000 and 1/3000 N HCl. The energy of Barbera wines and of common table wines is about that of 1/1000 N HCl. That of dry white wines is about that of 1/1700 N HCl, and that of Muscat wines, 1/3000 N HCl. That of vinegar examined is very much less, as AcOH is only slightly dissociated. In fermentation, different treatments produce quite remarkable changes in the acidic energy. Gypsum (150–300 g. per hectoliter) increased it considerably. Greater increase still was brought about by H_2SO_4 (50–100 g. per hectoliter). CaHPO_4 (150–300 g. per hectoliter) had no effect. H_3PO_4 was about equal in its effect to gypsum, but less than H_2SO_4 . S. LEVY.

Determination of arsenic in wine made from grapes that had been subjected to cuproarsenical treatment. E. GARINO. *Ann. R. accad. agricoltura Torino* 56, 78 (1914); through *Ann. chim. applicata* 3, 148.—In fermentation, As begins to have some action in quantities of 1% As_2O_3 , while Cu does not influence the decomp. of the sugar when added in doses of from 0.05–1.00%, since it becomes insol. The amts. of As met with in analysis of wines from grapes subjected to cuproarsenical treatment are very small, being less than the minimum therapeutic dose of 5 mg. and therefore need cause no alarm. S. LEVY.

Palm wine (laghbi) of the Tripoli oasis. DANTE BACHILLI. Tripoli. *Ann. chim. applicata* 3, 101-10(1915).—Three wines were analyzed, both unfermented and fermented. The fermentation took place at 12-15°, in 7-9 days, and the resulting wines were very light and sparkling and resembled cider. The fresh wines were slightly, the fermented wines distinctly acid. Wine (1) was from the palm *muftile*, wines (2) and (3) from the palm *tabuni*. Analyses, based on 1000 cc. liquid (1st value refers to fresh, 2nd value to fermented wine); sp. gr. (1) 1.0542, 1.0153; (2) 1.0679, 1.0285; (3) 1.0718, 1.0220; total acidity, as malic acid, (1) 0.31, 4.42; (2) 0.36, 5.89; (3) 0.06, 6.20; dry ext., (1) 143.89, 57.16; (2) 188.19, 97.24; (3) 182.43, 80.15; ash, (1) 1.81, 1.85; (2) 1.51, 2.04; (3) 2.17, 2.57; alkalinity of ash (in K_2CO_3 as % of ash), (1) 2.94, 2.54; (2) 2.79, 2.40; (3) 3.67, 3.41; succinic acid, (1) 0.35, (2) 0.33, (3) 0.45; reducing sugars as glucose, (1) 12.82, (2) 16.12, (3) 8.32; non-reducing sugars as saccharose, (1) 100.87; (2) 113.08, (3) 117.70; gum, (1) 9.12, (2) 10.84, (3) 17.04; mannite, (1) 4.98, (2) 5.10, (3) 4.12; glycerine, (1) 0.96, (2) 1.86, (3) 1.25; N, (1) 0.18, (2) 0.27, (3) 0.37; albuminous substances, (1) 1.12, (2) 1.69, (3) 2.31; peptic and mucilaginous substances, and those not detd., (1) 11.86, (2) 37.66, (3) 30.07; alc. by wt., (1) —, 45.10; (2) —, 46.30; (3) —, 45.70; volatile acidity as $AcOH$, (1) —, 1.02; (2) —, 1.14; (3) —, 0.72; residual sugar as glucose, (1) —, 10.40; (2) —, 12.36; (3) —, 10.96. The % comp. of the ash of (1) fresh wine was K_2O , 46.10; Na_2O , 10.40; MgO , 5.02; CaO , 3.20; Al_2O_3 , 3.54; Fe_2O_3 , 0.38; Cl , 13.91; P_2O_5 , 11.40; SO_3 , 5.30; SiO_2 , 0.72. S. LEVY.

The steaming of corn and its influence on the time of refining. R. KUSSEW. *Mitt. Brenneri Presshefe-Fabr.* 1913, No. 48; *Chem. Tech. Rept.* 38, 24(1914).—K. recommends a gradual increase of pressure in the steaming of corn. A final pressure of 2.5 atms. is most suitable. $CaSO_4$ aids in the opening of the grain, $Ca(HCO_3)_2$ retards the action; hence the water used should be treated with gypsum and Ca phosphate. Double conical boilers are recommended as especially advantageous.

J. S. G.

The scientific basis in the production of beer. E. WEINWURM. *Naturwissenschaft.* 3, 165-70(1915).—A review. C. G. F.

U. S., 1,136,559, Apr. 20. V. SLAVICK. In the continuous distillation and rectification of alcoholic liquids, the raw alc. vapor is divided into 2 portions. The non-cooled phlegms of one portion of the head products are purified and introduced at the beginning of the rectification into the alc. raw vapor of the second portion, this portion having been previously deprived of head products, leaving the tail products. The phlegms thus vaporized are impregnated with tail products and prevented from becoming satd. with alc.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Animal charcoal. HANS HELCH. *Pharm. Post* 47, 949-50(1914).—Tests of purity: (a) 0.1 g. finely sifted and dried (at 120°) charcoal should completely decolorize at least 20 cc. of a 1% soln. of methylene blue-HCl within 1 min. when shaken with it in a closed flask. (b) If 2.3 g. charcoal is shaken with 65 cc. of a 1% methylene blue-HCl soln., on drinking the mixt. no color should appear in the urine in 24 hrs. The lighter and more voluminous the charcoal the greater is its power of adsorption; for this reason blood charcoal is superior to bone charcoal. C. O. EWING.

The physiological assay of digitalis preparations. RAPP. Munich. *Pharm. Zentralhalle* 55, 961-4, 978-82(1914); cf. *C. A.* 9, 508; 8, 2778.—In the assay of digitalis

with frogs, concordant results were obtained by the 1 hr. method of Hale, which is described. Good results were also obtained on com. preps. of digitalis. Since there are seasonal and yearly variations in the frogs, each lot should be tested with the standard digitoxin of Killiani to det. its resistivity. The digitoxin to be tested should be taken up in 25% alc. and dilns. should also be made with 25% alc. The activity of com. preps. is preferably expressed in digitoxin units. C. O. EWING.

The qualitative separation and identification of some hydroxymethylantraquinones. E. M. BAILEY. *Am. J. Pharm.* **87**, 145-54(1915).—Expts. to find some color reactions which would serve to differentiate between the common cathartic drugs, senna, rhubarb, aloes and the various species of buckthorn—all characterized by a group of color principles known as hydroxymethylantraquinones—led to some interesting differences among the hydroxymethylantraquinones themselves, more especially between the dihydroxymethyl and trihydroxymethyl derivatives, chrysophanic acid and emodin, resp. The mixed color principles were obtained by hot extn. with benzene, as recommended by De la Rue and Müller (*J. Chem. Soc.* **10**, 298). This benzene soln. was then washed, first with portions of 5% $(\text{NH}_4)_2\text{CO}_3$ soln., then with 5% Na_2CO_3 and finally with 5% NaOH , thus removing unidentified anthraquinone derivs., emodin and chrysophanic acid in the order named. The 3 aq. solns. were then separately acidified and shaken out with ether, and the ether residues examd. directly or after recrystn. from alc. The differentiation of the several residues was made chiefly on the basis of their m. ps. and color reactions. The m. ps. are regarded rather as broadly differentiating between the substances sepd. than as precise observations intending to indicate states of purity. The color reactions were obtained by treating with concd. H_2SO_4 , concd. HNO_3 , and H_2O successively. The distinguishing features are that emodin gives an intense pink color immediately on addition of concd. H_2SO_4 , and a pink soln., or one with a decided pink tinge, on final diln. with H_2O ; chrysophanic acid gives an orange-red color with H_2SO_4 , and on final diln., a yellow soln. and a yellow ppt. The Na_2CO_3 -sol. color fraction derived from aloes is an exception to the behavior of emodin as derived from buckthorn, rhubarb, and senna. The unidentified hydroxymethylantraquinone, or mixt., obtained in the $(\text{NH}_4)_2\text{CO}_3$ fraction is characterized by an intense purple or violet color with concd. H_2SO_4 . These reactions may be summarized as follows: (1) Emodin, as derived from buckthorn, rhubarb and senna: with concd. H_2SO_4 = pink; + HNO_3 = yellow; + H_2O = pink soln. (2) Emodin, from aloes, $(\text{NH}_4)_2\text{CO}_3$ -sol.: with concd. H_2SO_4 = red, brownish; + HNO_3 = yellow; + H_2O = yellow soln. (3) Chrysophanic acid, as derived from all sources: with concd. H_2SO_4 = orange red; + HNO_3 = yellow; + H_2O = yellow soln. and ppt. (4) Unidentified hydroxymethylantraquinones, $(\text{NH}_4)_2\text{CO}_3$ -sol.: with concd. H_2SO_4 = purple or violet; + HNO_3 = yellow; + H_2O = yellow soln.

W. G. GAESSLER.

Finnish pharmacopeia last edition. Issued Jan. 1, 1915.—Revision occupied the comm. 6 yrs. The question of nomenclature was one of chief concern of the comm. The Latin won over the German.

A. R. ROSE.

Folium digitalis. J. W. HAMMER. *Svensk Farm. Tid.* **19**, 69-74(1915).—Exam. of a large number of samples gave a wide range of values varying with the source and time of storage. A loss of from 20.9 to 72.0% of original pharm. strength occurred in 8 months. Each lot should be tested separately before allowed to go into any prescription.

A. R. ROSE.

Strychnine and brucine content of nux vomica. JOHN E. ERICSON. *Svensk Farm. Tidskrift.* **19**, 74-7(1915).—A study of the prep. of nux vomica as given in the Swedish Pharm. This authority differs from the Eng. and Am. Pharms. in that the alkaloid is calcd. in the former as strychnine and brucine while in the latter it is valued on the basis of the strychnine alone. E. tested the methods of analysis in the Eng. Pharm.

and found them to accord with the theoretical values within 1%. In 12 samples of *nux vomica* ext. the total alkaloid was 13.1–27.5%; of this 34–88.6% was strychnine and 14–66% brucine. In 6 samples of powder and 6 of tincture, the variation of the total alkaloid was very great; the strychnine varied from 45 to 56% of the total alkaloid.

A. R. ROSE.

Detection of vanillin in quinine wines. A. C. CHAUVIN. *Ann. fals.* 7, 420–2 (1914); *J. Soc. Chem. Ind.* 34, 247.—Lecomte proposed the following test: Mix an ethereal ext. of the wine with dil. HCl and add an alc. soln. of phloroglucinol. In the presence of vanillin a red zone appears at the junction of the two liquids in about 10 min. C. states that this test is also given by furfural and its derivatives which are frequently present in quinine wines and therefore this reaction is not characteristic of vanillin.

H. R. SMITH.

Determination of iodine in pharmaceutical preparations. C. LORMAND. *Ann. fals.* 7, 432–41 (1914); *J. Soc. Chem. Ind.* 34, 248.—L. criticizes the methods given in the French Codex and establishes the following methods as being the best: In tincture of I a 5 g. sample is treated with 6 drops NaHSO₃ soln., dild. with H₂O and the excess bisulfite converted into the sulfite by 2 drops NaOH soln. This soln. is then treated with 5 drops HNO₃, boiled, and the I pptd. as AgI after the addition of more HNO₃. In the analysis of iodine-iodide ointment a portion of the free I may be absorbed by the fatty constituent. For iodo-tannin-phosphated wine treat 50 g. with milk of lime prepd. from 10 g. of lime, dil. to 250 cc., filter, and titrate the I in an aliquot part by the thiocyanate method.

H. R. SMITH.

Papain. H. F. MACMILLAN. *Chem. and Druggist* 1915, 133–6; *J. Soc. Chem. Ind.* 34, 246–7; cf. F. W. Heyl, *et al.*, *C. A.* 9, 235.—The papaw tree (*Carica papaya*) is largely grown in Ceylon, the Hawaiian Islands and the West Indies for its edible fruits and for the prepn. of papain. Papain is prepd. by scarifying the nearly mature green fruits, while still on the tree, with a bone or ivory knife, and collecting the milky, viscid exudate in porcelain, glass, or earthenware vessels. The juice rapidly coagulates and must be dried promptly to prevent decomp.; a trace of formalin may be added to the juice as a preservative. The coagulum is sometimes dried in the sun but preferably by artificial means. In Montserrat driers, 3 ft. by 3 ft. by 6 ft. in length, are used, having sides and ends of brick and open at the top. About 1 ft. below the top is an Fe sheet on which is a layer of sand 1–2 in. deep. The coagulum is spread upon brown linen held in frames which fit the top of the drier, or upon sheets of glass. Drying is effected at a low temp., sometimes below 38°. The dried material, when ground, yields a white or cream-colored powder, which is packed in tightly closed bottles. The exports of papain from Ceylon for the years 1911, 1912 and 1913 were: 6,611, 12,920 and 18,548 lbs. Considerable difference of opinion exists as to whether Ceylon or West Indian papain is the better, this being largely due to the general practice of adulterating papain, particularly Ceylon papain, with starch, rice, etc. Genuine papain has a slightly salt and somewhat acrid flavor, and a peculiar, characteristic smell. It should be crisp and not sticky.

F. W. SMITHER.

Antipyrine methylarsonate. L. BARTHE. *Bull. soc. pharm. Bordeaux* 1914, 348; *Pharm. J.* 94, 99 (1915).—The comp. of this compd. is O:As(OH)₂CH₃.2(C₁₁H₁₁N₂O)₄H₂O. For its prepn., add to a warm H₂O alc. soln. of methylarsonic acid 1 mol., antipyrine 2 mols., in concd. EtOH soln., boil the mixt., filter, allow to cryst. over H₂SO₄. The compd. is sol. in H₂O (28.5:100), sol. in EtOH, optically inactive. Towards KOH, NaOH, NH₄OH, CuSO₄, HNO₃, FeCl₃, I soln., alkaloidal reagents and NaClO soln., the compd. behaves like antipyrine dimethyl arsinat (see following abst.).

HNO_3 produces a beautiful currant red color. HgNO_3 causes a blackish ppt., not yellow as with antipyrine. S. WALDBOTT.

Antipyrine dimethylarsinate. L. BARTHE. *Bull. soc. pharm. Bordeaux* 1914, 353; *Pharm. J.* 94, 99(1915).—The comp. of this compd. is $\text{O:As(OH)(CH}_3)_2 \cdot (\text{C}_{11}\text{H}_{12}\text{N}_2\text{O})_2 \cdot 2\text{H}_2\text{O}$. For its prep., add to a concd. H_2O alc. soln. of O:As(OH)Me_2 1 mol., antipyrine 1 mol., dissolved in dil. EtOH, boil the mixt. and allow to cryst. over H_2SO_4 . The prepn. is sol. in H_2O (24.5:100), sol. in EtOH and m. below 100° . KOH or NaOH, but not NH_4OH form an emulsion-like white ppt. insol. in excess. CuSO_4 causes slight fluorescence but no ppt. $\text{NaNO}_3 + \text{AcOH}$ produces a fine blue color and FeCl_3 a blood red. 1 soln. and the usual alkaloidal reagents give ppts. NaClO soln. added to an aq. soln. of the prep. develops the odor of bitter almonds in a short time. S. W.

Absorptive power of magnesium carbonate for volatile products. J. MARANNE. *L'union pharm.* Dec. 1914, 517; *Pharm. J.* 94, 67(1915).—A cube of Mg carbonate sepd. from camphor only by stout paper (3 layers) acquired, after 2 months or less, a barely perceptible odor of camphor. On triturating it with H_2O , the odor became more distinct, but still was feeble; but when dissolved by citric acid, almost as strong an odor as that of spirit of camphor was developed. Hence the necessity of keeping Mg carbonate sepd. from volatile substances to avoid disagreeable flavor in certain preps., e. g., the limonade purgative of the French Pharm. S. WALDBOTT.

Bacterial versus vegetable toxins. J. S. WHITE. *Pharm. J.* 94, 156(1915).—The prep. of ricin and antiricin is described and their importance in the development of bacterial serum therapy is emphasized. S. WALDBOTT.

***o*-Acetoxybenzoic acid.** HENRY L. SMITH. London. *Pharm. J.* 94, 200-1, 311(1915).—Expts. on 6 samples, 1 being aspirin, show the pure compd. to be obtainable in trade. The color test for free salicylic acid detects the impure sample. Other tests applied are m. p. (the pure compd. m. 135° , *p*-acetoxybenzoic acid m. 185°), and the number of mg. required for complete sapon. of 1 g. of compd. (622.2 mg. for the pure compd.). In further tests, the number of cc. of 0.1 N Ba(OH)_2 required to neutralize 0.5 g. of sample was detd. at the end of $\frac{1}{2}$, 1, 2 and 3 hrs. in 200 cc. soln. of (a) H_2O , (b) 0.2% HCl, at 37° . This measures the relative hydrolysis of the samples under conditions prevailing in the stomach. The amts. of salicylic acid set free within 3 hrs. were detd. by color test, using a standard containing Fe alum and known equivs. of AcOH and salicylic acid. Intestinal hydrolysis was simulated with 200 cc. of 1% Na_2CO_3 acting on 0.5 g. of each sample at 37° , and the amt. of salicylic acid formed after 10, 20, 40, 60 and 80 min. was detd. by color test. All results are tabulated. In 1 impure sample, salicylic acid was detd. by the Br method. It gave 77.16%, aspirin gave 76.02%, theory 76.67%. The impurity recrystd. m. $159-61^\circ$ and was neutralized by 555 mg. KOH per 1 g. This indicates *o*-acetoxybenzoxybenzoic acid, due to faulty prepn. Crystn. of *o*-acetoxybenzoic acid from benzene (needles), or from Ac_2O or CCl_4 (plates), may account for difference in appearance of com. samples. S. W.

Discoloration of sodium salicylate solution by alkalis. H. G. GREENISH AND A. E. BRESLEY. *Pharm. J.* 94, 201-2(1915).—A soln. of Na salicylate to which NaHCO_3 has been added, gradually turns brownish, then dark brown or nearly black, eventually forming a black ppt. As a result of a series of expts., this seems to be due to the O of the air acting on the salicylate in the presence of Na sesquicarbonate. Why this salt should act so much more rapidly than either NaHCO_3 , Na_2CO_3 or NaOH, is yet unknown. Addition of about 1 grain of Na_2SO_3 or NaHSO_3 to the regular 8 oz. mixt. has a marked preservative effect. S. WALDBOTT.

The discovery of medicinal substances. A. HEFFTER. *Schweiz. Apoth. Ztg.* 53, 8-11(1915). S. WALDBOTT.

Common salt, and its use as medicine. F. BERGER. *Schweiz. Apoth. Ztg.* 53, 57-60, 73-6, 89-92, 103-6, 121-5, 132-5(1915).—A descriptive historical account of the occurrence, manuf. and uses of salt.
S. WALDBOTT.

The iodine absorption of pure oil of anise. E. MORIN. *Ann. chim. anal.* 20, 49-52(1915).—The I no. of oil of anise may be used as a basis for detg. the oil content of spirit of anise. The results of expts. based on the accepted I no. of oil of anise (1.391), were high and varied with the amt. of oil in soln. The I index of pure oil of anise as indicated by the results obtained is in the neighborhood of that detd. by Barentin (1.640).
M. I. W.

Analysis of cosmetics. FRANZ ADAM. *Arch. Chem. Mikros.* 7, 201-8(1914).—Pilocarpine and jaborandi leaves have acquired some reputation as hair tonics. A. reports a number of expts. to det. quantitatively the amt. of pilocarpine present in preps. of this type, either alone or in presence of other alkaloids. In extg. pilocarpine an excess of strong alkali or ammonia must be avoided. NaHCO_3 does not attack the lactone ring of pilocarpine and permits of a quantitative extn. by means of CHCl_3 . Ether is not so desirable as a solvent. A mixt. of CHCl_3 and alc. has no advantage over CHCl_3 alone. The quant. sepn. of pilocarpine from other alkaloids, particularly veratrine is difficult.

A needed change in ointment of zinc oxide, U. S. P. ERNEST R. JONES. *J. Am. Pharm. Assoc.* 4, 283-6(1915).—J. suggests the use of a mixt. of white petrolatum (65) and white wax (15) as a vehicle for ointment of zinc oxide.
M. I. W.

Morphine nitrate and morphine acetate. H. ENGELHARDT AND O. E. WINTERS. *J. Am. Pharm. Assoc.* 4, 288-91(1915).—A comparison of several methods for estg. the purity of morphine salts. From the expts. reported it is evident that the purity of morphine nitrate rarely is above 90% and that the purity of morphine acetate is far below 100% despite the fact that all of the samples examd. exhibited a strong odor of acetic acid.
M. I. W.

The composition and assay of heroine hydrochloride and diacetylmorphine hydrochloride. R. T. HARRIS AND A. M. GLOVER. *J. Am. Pharm. Assoc.* 4, 291-3(1915).—Commercial preps. were found to assay about 5% less alkaloid than was supposed to be present. Samples of heroine-HCl and of diacetylmorphine-HCl were found to vary in the amt. of water which they contained. For the estn. of the alkaloid and its salts the following method is recommended: Treat an amt. of the prepn. representing at least 0.1 g. of the alkaloid and contained in 10 cc. of soln. with 20 cc. CHCl₃ and sufficient 10% NH₄OH to render it slightly alk. After shaking vigorously, draw off the CHCl₃ into a container suitable for titrating. Repeat the extn. with CHCl₃ 3 times; then evap. the combined CHCl₃ ext. Add 5 cc. of 0.1 N HCl or sufficient to completely dissolve the alkaloidal residue; then add a few drops of cochineal soln. and titrate the excess of acid with 0.02 N NaOH. The results obtained are very close to the theoretical.

British pharmacopeia, 1914. M. I. WILBERT. *J. Am. Pharm. Assoc.* 4, 334-9 (1915).—A review of some of the features of the new Brit. Pharm.

M. I. W.

Preliminary note on a new pharmacodynamic assay method. PAUL S. PITTENGER AND CHAS. E. VANDERKLEED. *J. Am. Pharm. Assoc.* 4, 427-32(1915).—The authors propose the use of *Carassius auratus* (gold fish) as test animals for the digitalis series. Their expts. seem to indicate that the fish die in direct proportion to the strength of the soln. (1:75-1:3800) in which they are placed. Alc. to the extent of that contained in the U. S. P. tincture did not appear to affect the results. The work is to be continued. The authors conclude: (1) Gold fish are sensitive to variations of 2¹/₂% in the strength of the dilns. of digitalis in which they are placed. (2) Variations due to differences in the rate of absorption appear to be practically eliminated by the use of these animals. (3) Decreasing the strength of the diln. increases the sensitiveness of the test. (4) The wt. of the fish may be disregarded when making tests by this method. (5) Variations in the temp. markedly influence the resistance of gold fish to digitalis poisoning. (6) The individual variation in the susceptibility of gold fish is much less than that found in guinea pigs and frogs. (7) The gold fish method is unquestionably the simplest so far proposed and can easily be carried out by those not especially skilled in the pharmacodynamic art. (8) The inexpensiveness of the assay is decidedly in its favor. Gold fish of the proper size can be purchased wholesale for from 45 to 60 cents per dozen. (9) A sufficient number of animals can be procured at all seasons of the year.

M. I. W.

Examination of *Calycanthus floridus* for alkaloids. E. R. MILLER AND H. W. BROOKS. *J. Am. Pharm. Assoc.* 4, 433-4(1915).—A preliminary report. It is highly probable that the plant contains alkaloids, especially in the leaves, the ext. from which produced the most abundant pptn. with the alkaloidal reagents. The subject is to be further investigated.

M. I. W.

Estimation of calomel. R. I. GRANTHAM. *J. Am. Pharm. Assoc.* 4, 441-3(1915).—The iodometric method for the estn. of calomel is considered the most expeditious and convenient. It is not applicable to the analysis of calomel tablets or similar preps. which contain various other ingredients. The following method gave satisfactory results: 0.3 g. of calomel or an equivalent amt. of the powdered tablets is transferred to a 4-ounce Erlenmeyer flask, mixed with 0.5 g. of KClO₃ and 15 to 20 cc. of 10% HCl. The mixt. is digested on a steam bath for 15 min. and then filtered into a large beaker, the filter washed well with water and the filtrate made alk. with NH₄OH. After

the addition of a large excess of acetic acid and 1 to 3 g. of Na- or K-oxalate to the filtrate, the mixt. is boiled, stirring constantly in order to prevent bumping. After allowing the mixt. to settle it is filtered. The ppt. is washed 3 times with hot water by decantation, transferred to a filter and washed with hot water until free from chlorides, using for this purpose about 150 cc. of water in all. The filtrate and wash-water are then heated to about 80° and the Hg is pptd. with H_2S and estd. as HgS in the usual way.

M. I. W.

Some factors in drug absorption in frogs. W. F. BAKER. *J. Am. Pharm. Assoc.* 4, 443-5 (1915).—Among the objections that have been urged against the frog heart assay method for the digitalis bodies are the factors of absorption and the time-limit. The former is undoubtedly the most important, the latter being dependent upon the rate of absorption. While poor absorption may be met with during any time in the year it is especially likely to occur during the spring and late fall. German digitalin, digitoxin and prepn. containing acetic acid or glycerol are very prone to meet with poor absorption. From reported expts. it would appear that absorption may take place from the outer or inner surface of the skin or from the surface of the muscle. The mechanism of absorption or prevention of absorption is not under control of the central nervous system. Frogs kept in the light appear to absorb better than those kept in the dark. The matter of absorption is thought to be largely due to the health of the frogs and the condition under which they are kept, and if proper attention is paid to the handling, cleansing and storing of the frogs, but little difficulty will be experienced with poor absorption. Uniform and reliable results are obtained by the one-hour frog heart method.

M. I. W.

Stillingia sylvatica. E. R. MILLER, R. I. BROOKS AND C. P. RUTLEDGE. *J. Am. Pharm. Assoc.* 4, 445-8 (1915).—A review of the literature relating to the drug and report of expts. which indicate the presence of a small amt. of alkaloid. The amt. of residue obtained was not sufficient for further exam.

M. I. W.

Cannabis sativa. H. C. HAMILTON. *J. Am. Pharm. Assoc.* 4, 448-51 (1915).—The available evidence is contrary to the opinion that the medicinal value of *Cannabis sativa* is found only in the Indian-grown drug. The variable results, both clinical and pharmacological, which are obtainable even with active material, are due to the fact that not all test animals respond uniformly. Many of them must be rejected as not being sufficiently susceptible and even susceptible ones are not uniformly so. The activity of the drug appears to reside in the leaves and the flowering tops of the pistillate plants. With the exercise of caution in selecting the drug and insistence on certain qualities essential to a drug of good quality, American producers can supply material of value practically equal to that imported.

M. I. W.

Estimation of yellow phosphorus. H. ENGLHARDT AND O. E. WINTERS. *J. Am. Pharm. Assoc.* 4, 451-61 (1915).—For the estn. of P in soln. in CHCl_3 or any other suitable solvent, the $\text{Cu}(\text{NO}_3)_2$ method is to be preferred, because the mixt. of Cu phosphide, $\text{Cu}(\text{NO}_3)_2$, water, CHCl_3 , etc., can be treated directly with H_2O_2 soln. Straub's Cu method with Katz's modification was used as follows: The P is dissolved in CHCl_3 free from air and 10 cc. of the soln. corresponding to about 0.3656 g. of P is mixed in a bottle with 15 cc. of 10% $\text{Cu}(\text{NO}_3)_2$ soln. from which the air previously had been expelled by heating. The air in the bottle is replaced by CO_2 and the mixt. shaken for about $\frac{1}{4}$ hr. H_2O_2 is then added and the mixt. shaken again until the black color of the Cu phosphide has disappeared. The aq. soln. is sepd. from the CHCl_3 soln., the latter washed out twice with about 15 cc. of water and the combined aq. solns. and wash-water after the addition of HNO_3 are evapd. to about 5 cc., testing from time to time for unoxidized H_3PO_3 . When oxidation is complete the H_3PO_4 was estd. in the aq. liquid as Mg pyrophosphate. Should any Cu salt sep. together with

MgNH₄PO₄, the latter is re-dissolved and re-precipitated. In this way is obtained Mg pyrophosphate corresponding to 101.5% of the P taken for the estn. M. I. W.

The percentage of moisture lost in the preparation of some official and unofficial drugs. EDWIN L. NEWCOMB. *J. Am. Pharm. Assoc.* 4, 527-30(1915).—A report in tabular form of the average amt. of moisture lost in the drying of vegetable drugs collected during September and October of 1913 and 1914. M. I. W.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

An industrial method of preparation of copper sulfate. PIETRO FALCIOLA. Napoli. *Ann. chim. applicata* 3, 89-95(1915).—The exptl. app. consisted of a vertical glass tower 0.05 m. diam. and 1.4 m. high; it contained a m. height of Cu spherules resting on broken glass supported on a perforated porcelain plate at a constriction of the tower near its base. About 15 cm. of glass beads rested upon the Cu, and the tower was provided at the top with a separatory funnel, for introduction of acid, and a glass exit tube. The tower was loosely surrounded with an asbestos sleeve, so that the air between the sleeve and the tower at the bottom could be heated. The tower was placed in a porcelain dish so as to make a hydraulic seal with the various liquids used. SO₂ gas from burning S in a crucible was aspirated into the app., and entered at the porcelain plate by a glass tube passing through the hydraulic seal. The current of gas passing upward met a descending stream of properly regulated acids. In different expts. the acids were (1) a 1:1 mixt. of H₂SO₄ (d. 1.4) and conc. HNO₃; (2) dil. (1:3) HNO₃; (3) conc. H₂SO₄. In each case the soln. in the dish at the bottom contained CuSO₄ free of nitrate. The Cu is equally well attacked whether the entering gas is rich or poor in SO₂. F. suggests substituting the Glover tower used in mfg. chamber H₂SO₄ by his Cu tower. S. LEVY.

Colloidal graphite lubrication. W. W. ACHESON, JR. *Chem. Eng.* 21, 127-9 (1915).—A brief review and discussion of the prepn., properties, and uses of Acheson colloidal graphite. F. W. SMITHER.

U. S., 1,135,785, Apr. 13. H. A. FRASCH. Precipitating heavy, granular hydrated nickel oxide from $Ni(NH_4)_4Cl_2$ or $Ni(NH_4)_4SO_4$ by boiling the soln. with NH_4Cl or $(NH_4)_2SO_4$ and NH_4OH , concg. the NH_3 vaporized, by dephlegmation and returning sufficient of the concentrated soln. to the still to keep the b. soln. alk. Fe, Pb, Cu or Co may be similarly pptd.

U. S., 1,135,962, Apr. 13. J. W. AYLSWORTH. Molding hollow articles from phenol-formaldehyde condensation products on a core of material, *e. g.*, alloys of Sn, Pb, Bi and Cd, which has a m. p. between the final reaction temp. of the ingredients of the condensation product and the temp. at which the latter would be injured or deformed, hardening the article by heating and then raising the temp. to m. out of the core.

U. S., 1,135,981, Apr. 20. W. ASEF. Obtaining pure zinc oxide from waste liquors from wet copper extraction, etc., containing salts of Zn, Na and Fe. The liquor is treated with alkali or alk. earth carbonate or hydroxide to ppt. Zn and Fe, then oxidized with air and dild. with more of the original liquor to convert the pptd. Fe to the ferric state and dissolve the pptd. Zn. The soln., is then treated with an alkali to ppt. Zn and the remaining soln. containing Na salts is filtered off and evaporated. Before pptg. the Zn, Mn, Co and Ni are pptd. with hypochlorite.

U. S., 1,136,370, Apr. 20. J. A. SCHARWATH. Rendering paper, wood or cloth fire-proof and water-proof by dipping in a bath formed of MgO 10, Na silicate 150, fire clay 125, "red Mn oxide" 10, "Mn oxide" 50, and H_2O 300 parts, baking at a temp. of 150-260° and then dipping in a bath formed of MgO, $MgCl_2$ and H_2O .

U. S., 1,136,390, Apr. 20. A. G. ARTZ. Obtaining inorganic and organic values from kelp. Fresh kelp is pressed and algin pptd. from the sepd. expressed liquor by adding H_2SO_4 . The algin is filtered out and the filtrate neutralized with $CaCO_3$. Na_2CO_3 (5-15 lbs. per 100 gals.) is then added and the solids of the kelp, after macerating to a pulp, are treated with this soln. and boiled for about 6 hrs. to ext. more algin and sol. salts from the pulp. The algin is pptd. from the soln. with H_2SO_4 , $CaCO_3$ added to neutralize the soln. and the latter is evaporated to recover the salts contained in it.

U. S., 1,136,549, Apr. 20. C. H. MACDOWELL. Obtaining potash from alunite by calcining it to drive off SO_3 and SO_2 and then heating it to a higher temp. with 20-30% of coal, coke or lamp black to fume off the potash, which may be condensed in the solid form. The volatilization is assisted by a current of air, N or combustion gases and takes place at 800-1600°.

Brit., 28,334, Dec. 9, 1913. G. BERGEN. Fine crystals of common salt. See Ger., 269,427 (C. A. 8, 2041).

Brit., 28,390, Dec. 9, 1913. **BERLIN-ANHALTISCHE MASCHINENBAU AKT.-GES. Hydrogen.** See Fr., 465,575 (C. A. 8, 3491).

Brit., 28,469, Dec. 10, 1913. J. W. STUBBS and J. HOLLINS. A salt-evaporator, having externally heated tubes through which the brine circulates, is fitted with external downcomers shaped to fit the casing of the app. and decreasing in cross-sectional area from top to bottom. When the tubes are heated by furnace gases, they are arranged in a fire-brick casing, and the tube-plates are protected by false tube-plates. The space between the tube-plates may be cooled by a current of air or steam. A central passage is formed between the tubes for cleaning purposes; a damper baffles the furnace gases. The evaporators are arranged in series on the flue, and a by-pass flue together with the requisite dampers is provided for cutting out any desired evaporator. Baffles aid in the deposition of the salt in the lower chamber.

Brit., 28,737, Dec. 12, 1913. FARW. V. M. L. & B. The process of 3,662, 1913 (C. A. 8, 2607) for producing nitrogen oxides and nitrogen, is modified by adding an indifferent gas, such as N, to the mixt. of NH_3 of high concn. and air to be burnt catalytically, so as to give a resultant mixt. of N and N oxides containing no O. The addition is to avoid the considerable rise of temp. that takes place at the reaction surfaces.

Brit., 28,743, Dec. 12, 1913. R. BITHELL and J. A. BECK. A specially constructed tower to be used in place of the Glover and Gay-Lussac towers, in the manuf. of sulfuric acid. Cf. C. A. 9, 1229.

Brit., 29,053, Dec. 16, 1913. G. W. MALCOLM. Salt is made into blocks, cubes, or other bodies, each block containing a quantity such as a predetd. number of cupfuls, spoonfuls, or the like suitable for culinary recipes.

Fr., 466,478, Dec. 22, 1913. BADISCHE. Chromium salts tech. free from Fe are obtained from chromite or like Cr ores by heating to redness such ores (100 kg.) with reducing agents, such as coke, CO, coal (200 kg.) in the presence of Cl or HCl. The more volatile FeCl_3 (resulting from action of HCl) or Fe_2Cl_6 (from Cl) sublimes, while the CrCl_3 remains in the residue or is deposited in the less highly heated portions of the app. The ignited ore may be treated directly with a mixt. of CO and Cl.

Ger., 279,930, Jan. 27, 1914. DÜRENER FABRIK PRÄPARIERTER PAPIERE. Oil tracing paper or tracing linen is given a rough surface, during its impregnation or afterwards, by stamping, or other mechanical treatment.

Ger., 280,208, May 24, 1913. F. D. BELKNAP. A duplicating film is obtained by satg. paper with a bath consisting of H_2O 60, glycerol 15, gelatin 2, carrageen 2, and soft soap 2 parts by wt. The soft soap is preferably composed of K, Na, or NH_4 ricinoleates, with the anhydrides of ricinoleic and sulfuricinoleic acids. Cf. C. A. 8, 2925.

Ger., 280,500, Jan. 25, 1912. J. A. WHEELER. Mfg. products from artificial wood by compressing a plastic mass composed of a filler, a small amt. of a fire-proofing binder, and H_2O . Perforated sheets are run between the hot rolls and the material, to permit the escape of the moisture.

Ger., 280,738, Dec. 25, 1913. A. HAMBLOCH and S. GELLER. Magnesium carbonate is obtained from calcareous MgCO_3 and Mg silicates. The Mg is sepd. from the reaction mixt., together with the alkali carbonate used in the process, in the form of a salt sol. at the temp. used, while the Ca remains at the temp. as a residue. The native or calcined minerals are comminuted and mixed with alkali carbonates or bicarbonates, dissolved in H_2O , satd. with CO_2 , and then heated to 60–70°. The soln., containing the Mg as the double alkali salt, is sepd. from the pptd. CaCO_3 and the other solid residues, and decompd. by heating to 100° into insol. MgCO_3 and alkali carbonate which remains in soln. The latter can be used in working more calcareous

Mg minerals, as can also the CO_2 if this is collected. The residues contain, besides CaCO_3 , the Fe of the mineral and the SiO_2 and Al_2O_3 sepd. by the CO_2 . The alkali carbonate accelerates catalytically the absorption and the action or passage of the CO_2 , and also effects the sepn. of the Fe with the CaCO_3 , leaving a pure MgCO_3 . Cf. C. A. 9, 1377.

Ger., 280,915, Aug. 30, 1913. Addition to 271,246 (C. A. 8, 2465). G. SAUER-BREY, MASCHINENFABRIK A.-G. Removing crystals deposited from hot satd. solns., according to the principal process, by directing against the crystal mass a stream of the mother liquor at a pressure of 5-6 atm.

Ger., 280,922, Dec. 24, 1913. GENTHNER CARTONPAPIERFABRIK. In mfg. color- or bronze-foils, the material is applied to a thin paper, or the like, which is destroyed in order that the foil need not be removed. This is accomplished by applying to the paper, before or after applying the material, a dil. (10%) H_2SO_4 , heating to destroy the paper.

Ger., 280,960, July 14, 1912. BAYER & Co. Sulfur trioxide. See Brit., 15,165, 1913 (C. A. 9, 131).

Ger., 280,964, Aug. 14, 1913. H. DICKE. Fe scrap is ignited in retorts, shafts, or the like, and steam is continuously conducted over it, to produce hydrogen. The Fe_2O_3 produced is charged into the blast furnace, or made into steel in the Martin furnace. The H is 97-98% pure. Cf. C. A. 9, 1099.

Ger., 280,965, Aug. 30, 1913. R. SCHALL and STICKSTOFFWERKE AKT.-GES. Mfg. highly concentrated nitric acid by heating a mixt. of dil. HNO_3 and a drying agent. The mixt. is led through a heated chamber provided with heating members extending inwardly from the heated surfaces, thereby increasing the length of the passage to be traversed by the mixt. A suitable arrangement is shown. The drum *M* is provided with heating mantle *B*. Ledges *R* are arranged internally, and upon these the aq. HNO_3 flows, entering at the inlet *C*. The highly conc. acid is withdrawn at *D*, while the drying agent passes out at *E*. The tubes and ledges are made of acid-proof alloys of Fe with Si or Cr.

Ger., 280,966, Feb. 16, 1913. O. BENDER. Obtaining active oxygen and nitrogen by continuously supplying H_2O , which has been treated under pressure with N and O, to the porous walls of a hermetically closed, heated generator. If H_2O , satd. with air, be brought into contact with the porous walls of the heated generator, the H_2O which has been forced into the walls of the furnace is gradually vaporized, and the steam is

forced through the pores into the interior. This vapor, containing O-N, is drawn off with the flue gases, and remains as an active mixt. in the gaseous state, free from its soln. in H_2O on account of the reduction of pressure. By sudden cooling of the flue gases the steam is condensed and the active gas mixt. can be withdrawn for use. If, e. g., this mixt. is brought into contact with H_2O , NH_4NO_3 is formed. This mixt. can also be used for converting SO_2 into SO_3 or H_2SO_4 , as NO is formed and this acts in the known manner on the SO_2 vapors. Also this mixt. can be employed for the sterilization of potable water, river H_2O , and the like, small amts. of the mixt. serving to

sterilize large amts. of H_2O . A suitable generator is shown. *A* is the burner, *B* and *C* are inlet and outlet tubes for the cooling H_2O , *F* is the cooling device, *F* is the gas outlet, *G* and *H* are the H_2O and air inlets, while air is fed through tube *D*, and gas is supplied through *E*. After the burner *A* has heated the generator walls to a sufficiently high temp., the resistance at *F* is regulated to produce the desired pressure within the generator. At the same time, H_2O and air are introduced through *G* and *H*, the air being absorbed by the H_2O in proportion to the pressure. This H_2O then passes through the top of the generator and mixes with the combustion gases as steam. As a result of passage through the porous masonry, the *N* and *O* are rendered active, and combine with the elements of H_2O . If the generator be heated with coal, the excess of air must be such that 9–12% free *O* is present to 10–12% of CO_2 .

Ger., 280,967, Jan. 27, 1914. **ÖSTERREICHISCHER VEREIN FÜR CHEM. UND METALLURGISCHE PRODUKTION.** When NH_4NO_3 is substituted for $NaNO_3$ in the production of nitric acid, a considerable amt. of HNO_3 is lost on account of the high temp. used, since, according to Berthelot, NH_4NO_3 m. 152° and begins to decomp. when in *Fe* vessels. The salt decomp. completely at 185° with liberation of N_2O . To avoid this decompn., the amt. of H_2SO_4 used is controlled so that the expulsion of the HNO_3 is complete below 152 or 185° . This is effected readily by apportioning the salt and acid so that at least 1 mol. H_2SO_4 is present to each mol. NH_4NO_3 . As a result, the reaction product is completely fused, and the HNO_3 expelled, at not much above 120° , without decompn. of the NH_4NO_3 . Pure acid can be obtained in this manner from low grade impure acid such as is obtained by the air-*N* processes. The excess H_2SO_4 can be converted into com. $(NH_4)_2SO_4$ by neutralization with NH_4OH .

Ger., 280,969, Apr. 17, 1914. **M. MELAMID and L. GRÖTZINGER.** Purifying technical phosphoric acid, which contains impurities such as *Fe*, *As*, *Ca* salts, etc. by dilg. it and heating it with tar or tar oils or tar derivs. for a long time. The heating is effected while stirring, in the presence of indifferent gases or vapors such as *N*, *H*, *O*, or air. *E. g.*, 100 kg. tech. H_3PO_4 of 55° Bé. are dild. with H_2O to 25° Bé. From 5 to 10 times its wt. of tar oil is added, and the mixt. is heated in the presence of *N* with continued stirring. After 2–4 hrs. the mass is allowed to settle and the acid is poured off and filtered. The product is pure. If filtered again through bone-black the product is crystal clear.

Ger., 281,005, Jan. 18, 1914. **Z. LITTMANN.** App. for mfg. sulfuric acid, with a view to its intensive production and the economy of space. The course of the gases through the *Pb* towers is detd. by the contraction due to the localized chem. reactions.

Two towers of a group are shown, *a* and *b* in the drawing. These towers are connected by means of a tube, *c*, which extends from the lower portion of 1 tower to the upper portion of the other. Two branch tubes *d, d* are provided to connect tower *a* with *c* at the middle and near the top of the latter. The upper branch tube *d* is provided with a damper, *e*, for regulating the flow of gases according to the reaction. These tower may be employed alone or in conjunction with the usual *Pb* chambers. They may also be employed with or without filling and with or without the use of a trickling liquid.

Ger., 281,135, Dec. 24, 1912. **E. HOEFLING.** In the construction of a reaction tower system for the manuf. of sulfuric acid, a filling of systematically arranged tubes is used. The towers are furnished with tubes *A*, provided with openings and division plates, so that a large number of reaction towers is secured without direct channels.

The tubes are laid cross-wise over one another, fitting together with corresponding recesses, and communicating with each other through a plurality of openings. Plates *B* are fitted in each layer of tubes, thereby dividing it into 2 chambers, each of which constitutes a reaction tower. The tubes, and also the plates, can be provided with double conical openings so that the acid can enter readily from above, and the gases can pass up readily from below. To aid the reaction, these openings may be provided with grooves, similar to rifling.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The conduct of sulfur, selenium and tellurium in sodium calcium silicate glasses, with special reference to color. P. FENAROLI. *Mailand. Kolloid-Z.* 16, 53-9 (1915).—In extremely alkaline glasses, and under reducing conditions, polysulfides, polytellurides and polyselenides give colors to the glass about the same as they give to a water soln., and the glasses are optically empty. In a borax, or more acid glass, submicrons appear in the glass, and the color of the S glass changes to blue, the Se glass becomes red or rose colored and the Te glass blue. A glass of high viscosity shows greater tendency to give the color characteristic of submicrons of the free element than that of the polysulfide, -selenide or -telluride.

H. I. MATTILL.

Fireclay goods and their use in gas works. T. HOLGATE. *J. Gas Lighting* 128, 292-4, 363-4, 480-1, 536-7, 599-600, 661.—Results were obtained on the effect of pressure on the m. p. with both English and American fireclays over a range from atmospheric up to 125 lbs. per sq. in. additional pressure; the depression of the m. p. is about 2.5-4° per lb. pressure. A typical china clay of first class quality, normally m. 1770°, m. 1410° under a load of 112 lbs. per sq. in. whereas another clay melted under corresponding condition at 1750° and 1580°, resp. Uniformity of testing and treatment of specimens is urged. H. suggests that the high temp. at which the clays are burned may also influence the nature of the finished product and he illustrates the importance of the amt. of combined water by reference to some recent tests on fireclays in the Glenboig district. Stress is laid on the necessity of keeping fuel ash, often highly ferruginous, from contact with brickwork. The injurious effects of Fe oxides on firebrick increases in order Fe_2O_3 , Fe_3O_4 , FeO ; consequently reduction of Fe_2O_3 by furnace gases must be prevented. All magnetic Fe compds. and pyrites should be removed from the clays. The electro-osmotic process of purifying clay is referred to. Cf. Ormandy, *C. A.* 8, 800, 2043.

U. S., 1,136,832, Apr. 20. C. PAQUET. **Glass-furnace and pot.**

Brit., 28,326, Dec. 9, 1913. J. F. DAVY, P. H. MELLOR, A. A. LINES and H. J. YATES. **Radiants for gas-fires** are constructed with a metal reinforcement. A skeleton of metal wire, strips, or perforated sheets is dipped into a slip or thick fluid of refractory material consisting, for example, of clay, sawdust, burnt clay, sand, emery, carborundum, steatite, or the like, with or without Na silicate or pearl ash, the whole being mixed with H₂O. The slip adheres to the skeleton, and the radiant is then baked.

Brit., 28,398, Dec. 9, 1913. L. HONIGMANN. **Enamelling metals.** See Fr., 465,574 (C. A. 8, 3495).

Brit., 29,082, Dec. 17, 1913. K. A. MANKAU. A refractory substance consists of limestone to which have been added small quantities of oxides of the type RO, and R₂O, so as to produce on burning polyacid and polybasic spinels in the mass, as described in 23,725, 1912 (C. A. 8, 1336). The foundation material may consist of limestone to which has been added 4-12% of magnesite or chrome Fe ore, in which case the other oxides added are correspondingly modified to produce about 6% of a polybasic and polyacid spinels.

Ger., 280,940, Nov. 22, 1913. F. SCHÖNBACH and M. TISCHER. **Decorating aluminium** by burning in fusion colors. The pigments are applied to the previously well cleaned surface (without the aid of a glass flux), by means of a brush, stamp, stencil, or compressed air, and they are then burned in a muffle at a temp. of 500-550°. The luster colors, gold (soln. of Au₂S in oils), glass color, and enamel, are used. These are the same colors used for decorating glass, porcelain, stone-ware, and enamelled wares. The decoration is said to be very permanent and resistant.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY:

The hydration of calcium sulfate hemihydrate. PAUL ROHLAND. Stuttgart. *Z. Anorg. Chem.* 89, 352-4(1914).—The acceleration of the setting of CaSO₄·0.5H₂O by electrolytes accompanies an increase in the solubility and *vice versa*; in some cases in which the effect of the added salt on the solubility of CaSO₄·0.5H₂O changes sign the effect of added electrolyte in the rate of setting shows a similar effect. G. W. M.

The compound 8CaO·Al₂O₃·2SiO₂, the chief component (alite) of Portland cement clinker. ERNST JÄNECKE. Hannover. *Z. anorg. Chem.* 89, 355-69(1914); cf. C. A. 6, 1828-9.—J. detd. cooling curves in mixts. at and near to the above comp. in the system CaO-Al₂O₃-SiO₂, on the basis of which he asserts that there is a max. in the fusion surface at the above comp. and 1385°. This conclusion is at variance with the results of Rankin (C. A. 9, 702), probably because of the well-known undercooling which takes place with silicate mixts.

GEORGE W. MOREY.

Device tests adhesiveness of California road oils. ANON. *Eng. Record* 71, 329(1915).—The methods and app. for testing viscosity and adhesion are described. Comparative results of these tests on different qualities of oil are given. F. B.

Retardation of the oxidation of iron (ROHLAND) 9.

U. S., 1,135,176, Apr. 13. E. GOSSETT. Artificial building stone formed of rock salt 16, Fe oxide 6, volcanic ash 10, sand 20, ground asbestos 4, powdered rock 10, and FeSO_4 1 part.

U. S., 1,136,724, Apr. 20. A. SCHMIDT. A fungicidal composition for preserving wood is made by mixing Na dinitrophenolate or similar nitro compd. with about 1-1.5 times its wt. of ZnCl_2 or other fire-proofing salt. The latter renders the nitro compd. non-explosive.

Ger., 281,006, Mar. 5, 1914. DR. RUDOLF VAN DER LEEDEN. Obtaining an aluminium silicate, serving as a crude product for the manuf. of cement, and also the alkalis, from natural double silicates.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Chlorides in coal. A. DE WAELE. *Colliery Guardian* 109, 600(1915).—The cause of an abnormal corrosion of a boiler was traced to the presence of 0.22% of Cl in the coal used.

H. I. OLIN.

The composition of and decomposition products of the bituminous rocks of Estland (Baltic Russia). FOKIN. *Gorny J. (Russ-Bergjournal)* 1913, 117; *Chem. Tech. Rept.* 38, 391(1914).—The org. substances are of light yellow color and cannot be extrd. with org. solvents. They can only be obtained in a pure state by the soln. of the mineral constituents of the rocks. Analyses show 8.31-9.02 H, 72.37-72.82 C, 0.56-0.68 N, 14.1-16.24 O, 1.6-1.92% S, and a sp. gr. of 1.14. The mass is slightly hygroscopic. The presence of S and N indicate an animal origin. Dry distn. gives 20% of C and 80% of oil and gas. The oily distillate amounts to about 60% and is very sol. in C_6H_6 , but difficultly sol. in benzine. The oil has a sp. gr. of 0.920-0.945, coeff. of expansion of 0.00057 and viscosity 7.15. Analyses give 80.1-81.85 C, 8.71-10.50 H, 7.25-8.71 O and 0.29-0.40% S. Re-distn. gives 7.6% benzine (at 150°) and not much petroleum. The residues are suitable for fuel only. Paraffin, anthracene and naphthalene could not be found. The oil might find use as an antiseptic.

J. S. G.

Oils from peat. F. M. PERKIN. *J. Inst. Petrol. Technologists* 1, 76-84(1914); *J. Soc. Chem. Ind.* 34, 132.—The destructive distn. of dry peat yields a thick tar containing paraffin wax, and an aq. distillate containing NH_3 , AcOH, acetone and MeOH. The gases evolved are sufficient to carbonize the peat if it has been previously dried to a H_2O content of 20%. Coke hard enough for metallurgical purposes is obtained from suitably dried briquetted peat. The tar is fractionated, finally with superheated steam, to prevent carbonization, and the fractions are washed with alkali and acid. The oils are largely paraffinoid. The yield from a briquetted Yorkshire peat was 38 gals. per ton, giving on fractionation 1.35% of oil of d. 0.867 below 150°, 29.90% of d. 0.953 below 250°, 50.00% of d. 0.941 above 250°, and a residue of hard pitch. The last fraction contained 6% of paraffin wax. From 11 to 22 lbs. of $(\text{NH}_4)_2\text{SO}_4$ per ton were also obtained. The cost of dried peat should not exceed \$1.10 per ton, and on this basis the production of oil and C should be remunerative. Details of a plant to treat 50 tons of wet peat per day show that the capital required is about \$15,000. Cf. C. A. 8, 2239.

F. W. SMITHER.

Determination of hydrogen sulfide in coal gas. A. B. WAY. *J. Gas Lighting* 128, 660-1(1915).—A thermometer passes through one hole of a rubber stopper inserted to

a marked depth in a wide-mouth 2000 cc. bottle a glass inlet and an outlet tube provided with rubber connections and pinchcocks through the other 2 holes. The pressure in the bottle is brought to the normal, when the sample has cooled, by opening one of the pinchcocks while the loose end of the rubber tube is immersed $\frac{1}{4}$ in. in water. The cock is closed, the tube connected with a leveling bottle and the other tube with a buret containing a soln. of CdCl_2 (20 g. CdCl_2 to 125 cc. H_2O + 50 cc. strong NH_4OH , filtered and dild. to 1 l. with 300 cc. NH_4OH and the balance H_2O). 30 cc. of this soln. are introduced into the gas bottle and the buret and leveling bottle are disconnected. After shaking, the pressure is released by slowly opening the pinchcock and the contents of the bottle are put on a dry filter and washed with H_2O . Transfer the filter and contents to bottle, run in an excess of 0.05 N I soln., 3 cc. starch soln. and about 200 cc. of H_2O and 50 cc. HCl . The stopper is inserted, the bottle shaken for a minute or two and the excess of I titrated with 0.05 N $\text{Na}_2\text{S}_2\text{O}_3$ soln. Using 0.05 N I soln. and a bottle holding 2000 cc., 1 cc. of I soln. represents 18.62 grains of H_2S per 100 cu. ft. of gas. C. A. COLE.

Factory plan for production of ammonium sulfate from gas-water, with continuous removal of the salt. G. BARNICK. Leipzig. *Chem. App.* 2, 61-3(1915).—The gas water, gently warmed in *A*, flows to the pre-heater *B*, thence to the tower *C*, where it is mixed with milk of lime from *E*. Steam is blown into *D* and passes through

C to the trap *G*, from which the NH_3 , CO_2 and H_2S pass to the saturator *H*, the CO_2 and H_2S passing through *K* and the coil in *A* to the air. Common 60° Bé. H_2SO_4 , as free as possible of *As*, dild. to about 42° (55% H_2SO_4) with mother liquor from the centrifugal is run from *O* to the saturator *H*. The crystal deposited in *H* is sent by the injector *I* through *L* and *M* to the centrifugal *Z*, driven by engine *P*. J. H. MOORE.

Improving quality of ammonium sulfate. R. J. MILBOURNE. *Chem. Trade J.* 56, 285(1915).—M. urges that the mfrs. of $(\text{NH}_4)_2\text{SO}_4$ have some standard for production and for controlling the product of their plants. He advises greater care in controlling the free acid and also that part of the operation that effects the color of the salt or its appearance when shipped. C. A. COLE.

Manufacture of ammonium sulfate. ANON. *Gas World* 62, *By-products and coking section*, 13(1915).—It was originally believed that a low temp. was essential for the production of a white sulfate, but it has been found practical to ext. the tar without cooling the gas. The most desirable factor is absolute regularity of working conditions. It is generally accepted that 5% of free acid in the saturator liquor gives the best results. To have a proper idea of conditions it is necessary to know the free acid and the Twaddel. The most suitable strength for the mother liquor is 58° Tw.

M. L. TROWBRIDGE.

Coke. V. B. LEWIS. *J. Gas Lighting* 129, 201-4(1915); *J. Soc. Chem. Ind.* 34, 163.—L. advocates carbonizing coal at about 1050° and dilg. the rich gas so made by passing "blue" water-gas into the foul main. In this way it is claimed that the max. quantity of gas of about 560 B. t. u. per cu. ft. will be obtained together with a fair quantity of tar of good quality, the highest yield of NH_3 and a good coke containing 5.6% volatile matter. The coke will stand transport, will ignite and burn easily and should be very suitable for domestic use.

C. A. COLE.

Effect of salt in coke ovens. J. W. BROADHEAD. *Colliery Guardian* 109, 546 (1915).—Common salt present in certain British coals above 0.33% causes trouble in the coke oven by decomposing at 700° into Na and Cl. The latter unites with NH_3 to form NH_4Cl , which condenses and stops the main. The free Na attacks and pits the silicious fire brick of the oven at a temp. of about 1100°. Magnesite bricks resist corrosion.

In the process of obtaining ammonium sulfate from coal-gas described in the principal patent, in which the crude gas is cooled and then reheated by a circulating liquor and is further cooled between these 2 operations, the reheated gas being passed into a saturator, a part of the cooled gas issuing from the saturator is led back to the main gas current between the 1st cooler and the reheater, and this additional gas may be 1st heated by the hot crude gas and may be 1st preheated by the hot gas issuing from the saturator.

Brit., 28,285, Dec. 8, 1913. J. I. ROBIN. **Fabric for incandescent mantles** is knitted or woven from 2 or more threads, filaments, etc., 1 or more being previously impregnated and the rest unimpregnated. Incineration of the mantle destroys the unimpregnated threads, leaving an open and evenly spaced fabric. The impregnated and unimpregnated threads may be of different colors, and a thread may be used which has been made wavy by being knitted into a fabric and then pulled out.

Brit., 28,389, Dec. 9, 1913. BERLIN-ANHALTISCHE MASCHINENBAU AKT.-GES. **Purifying generator gas**, water-gas, or the like, by passing it, while hot, through heated Fe turnings in a retort-like vessel having porous walls. The gases enter by a pipe, the porous walls keep back the soot in the gases, and the Fe turnings heated by the hot gases in the annular space remove the S compds., the purified gas leaving by a suitable outlet. Cf. C. A. 8, 2478.

Brit., 28,682, Dec. 12, 1913. J. M. WALLWIN and F. S. SINNATT. For the purpose of preventing the clogging up of the mass of material for **purifying producer and like gas**, cork is mixed with such material and the mixt. is placed on or between the grids of the purifier. Suitable proportions are 1 part by vol. of cork to 3 parts of purifying material.

Brit., 29,009, Dec. 16, 1913. H. J. PHILLIPS and A. PHILLIPS. Coal-dust is made into **briquets** by (1) grinding with 45-60% H_2O to a pulp, (2) briquetting at once without allowing settling in molds from which the H_2O can escape, under a pressure of 3 to 5 tons to the sq. in.; (3) drying the briquets by passing them through a tunnel kiln, the initial temp. of which may be 80° and is below b. p. to avoid cracking, and the final temp. somewhat below that at which the coal begins to decompose, ranging from 250° for semi-bituminous coal up to 500° for anthracite, and (4) further compressing them while yet soft under 5 to 15 tons to the sq. in. in molds heated by superheated steam. A binder that will stand the temp. employed may be added, but is not necessary.

Brit., 29,069, Dec. 16, 1913. G. HINSELMANN. In a **coke oven** heated by vertical flues in the side walls, the heating is equalized either by starting some of the flues at different levels from the others or by constricting their lower portions to prevent immediate full development of the flame.

Brit., 29,088, Dec. 17, 1913. T. R. WOLLASTON. The steam-generator or vaporizer of a **gas producer** is fitted with Perkins' tubes depending within the fuel-chamber. The steam may pass through an injection nozzle, or the air may be supplied by a fan or blower and mixed with steam before or after traversing a jacket.

Brit., 29,089, Dec. 17, 1913. T. R. WOLLASTON. In a **gas producer**, a rotary or oscillatory boiler is mounted on rollers on the top of the shell and has depending hollow members projecting into the fuel bed. These members act as stirrers and distributors of fuel as well as transmitters of heat from the fuel bed to the boiler. The steam from the boiler, supplied by H_2O , serves to draw in air by a nozzle, the mixt. being superheated in a jacket surrounding the producer before being delivered by a pipe to any desired height in the fuel bed.

Brit., 28,742, June 12, 1914. A. W. DIXON, W. H. PEARSON and BROWN & Co. Construction of a **producer grate**.

Ger., 280,746, Sept. 4, 1913. J. BUEB. In mfg. **gas** in vertical retorts or chambers, steam is introduced until the excessive pressure, resulting from rich coal during the 1st period of distn., is no longer produced. The effect of the steam is to immediately reduce such excessive pressure.

Ger., 280,846, Aug. 14, 1912. W. DEEG. **Air-gas generator** with motor-driven air compressor and wet gas meter arranged before the carbureter.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Petroleum industry in 1912 and 1913. RICHARD KISSLING. *Chem. Ztg.* 38, 1273-6, 1284-6, 1290-3(1914). E. J. C.

The question of the optical activity of petroleum. J. MARCUSSEN. *Chem. Ztg.* 39, 1243(1915); through *Chem. Zentr.* 1915, I, 69.—M. states that the facts published by v. Trautenberg (cf. *C. A.* 9, 372) had been previously reported by him (*Mitt. Techn. Vers.-A. Berlin* 22, 96-110(1904).—The behavior of cholesterol favors the assumption that the optical activity of mineral oils is due to satd. hydrocarbons formed from cholesterol compds. F. W. SMITHER.

Determination of percentage of toluene in commercial solvent naphtha. H. G. COLMAN. *J. Gas Lighting* 129, 314-5(1915).—100 cc. of the sample is distd. at the rate of one drop per second from a round-bottomed flask provided with a Young 12-bulb or other efficient fractionating column, and the distillate is collected up to 138°. If this does not amount to 35 cc., another 100 cc. is fractionated and the distillates combined. If the combined distillates do not amount to 35 cc. the sample is considered practically free from toluene. To 35 cc. of the distillate add 50 cc. toluene and 15 cc. C_6H_6 and distil as in detn. of toluene in com. toluene (*C. A.* 9, 962). If the sample contains hydrocarbons with a b. p. near that of toluene correct as follows: For each 0.001 that the sp. gr. of the fraction 105-17° is below 0.868 deduct 0.75 from the % of toluene found by the table in the previous article. This gives cc. of toluene in the mixt., from which, after subtracting the 50 cc. added, can be calcd. the number of cc. in the sample of naphtha. C. A. COLE.

Optical investigation of South Bolivian and Argentine naphthas. II. M. A. RAKUZIN. *J. Russ. Phys. Chem. Soc.* 47, 58-62(1915).—An optical exam. of naphtha from Cuazazutti, Bolivia, both in the original state, in its soln. in C_6H_6 , and after sepn. into fractions by distn., showed that it was optically semi-transparent, its carbonization const. being nearly 1. Tables are given showing the color, sp. gr., rotation and behavior with CCl_4 , CO_2H of the different fractions. An exam. was also made of 2 samples of naphtha from Augua Caliente and Ijira, Argentine Republic. Their carbonizations const. were greater than 1, and their sp. grs. rather high. This is ascribed to these naphthas having collected on the surface of the soil. In filtering upwards they lost many of their carburetted compds. while exposure to the air deprived them of the more volatile lighter components. H. M. GORDIN.

Investigations of natural and artificial asphalts. J. MARCUSSEN. *Mitt. K. Materialprüfungsamt.* 32, 419-31(1914); see *C. A.* 9, 146. F. W. SMITHER.

Rock asphalts of Oklahoma and their use in paving. L. C. SNIDER. *Petroleum* 9, 974-6(1914).—The amt. of these deposits is estimated at from 2 to 13 million tons. The bitumen is incorporated in sandstone, sand, and limestone. It is more viscous and softer than that from Trinidad and Bermudez asphalt. A sample from Ardmore contained 9.97% sol. in CS_2 ; this bitumen possessed a sp. gr. of 1.032, 5.4 mm. penetration at 25° (100 g., 5 secs.); loss when heated at 163° for 5 hrs. 4.11%; 22.44% insol. in 86° Bé. naphtha; and 1.78% mineral matter. O. E. BRANSKY.

Colloidal graphite lubrication (ACHESON) 18. Oils from peat (PERKIN) 21. Bituminous rocks of Estland (FOKIN) 21. Device tests adhesiveness of California roads oils 20.

U. S., 1,135,506, Apr. 13. J. A. DUBBS. Distilling asphaltic petroleum by mixing it with 1-5% of H_2O and heating under 50-300 lbs. pressure per sq. in. so that the steam generated promotes vaporization.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Recent progress in the analysis of cellulose and cellulose derivatives. J. F. BRIGGS. *Analyst* 40, 107-20(1915).—A review. P. B. DUNBAR.

Durability tests of parchment paper, imitation parchment paper and pergamin paper. C. BARTSCH. *Mitt. Kgl. Materialprüfungsamt* 32, 510-8(1914); *Papier Ztg.* 40, 378(1915); *Papier-Fabrikant* 13, 149-52, 165-9(1915).—Tests of these 3 varieties of paper over a period of 7 yrs. showed a marked decrease in stretch and folding strength especially when the papers have been stored in a dry room. The decrease is greatest in the case of true parchment papers. Tearing strength suffers but little decrease in all cases. Loss in strength of true parchment papers is directly proportional to their acid content. The best conditions for storage are in a slightly moist atmosphere with fairly const. humidity. Loss in strength on heating at 60° for 3 days is in fairly close agreement with the loss on storing 7 yrs., but a series of papers which differ but slightly cannot be accurately graded by this method. V. NUNEZ.

Determination of the air content of paper. G. LUDWIG. *Papier-Fabrikant* 13, 137-40, 153-4, 169-70, 181-5(1915).—Three methods are given: (1) For use with paper which is readily permeable: an app. is described which permits the accurate measurement of the vol. of air contained by the paper, depending on the difference in level of petroleum contained in a vessel with a calibrated tubulature before and after the introduction of a known vol. of the paper. (2) In case of papers not readily permeable, a known wt. and vol. is disintegrated by boiling with water and its sp. gr. detd. by weighing in a pycnometer bottle, due regard being given to the effect of the buoyancy of air in the original weighing. (3) If the comp. of a paper and the sp. gr. of its several components are known, the air content of a known vol. may be calc. directly. V. NUNEZ.

U. S., 1,136,248, Apr. 30. W. G. LINDSAY. Making a plastic mixture of acetylcellulose, for making films, etc., by working up acetone-sol. acetylcellulose with about 25-40% its wt. of tetrachloroethyl acetanilide or trichloromethyl acetanilide and about 40-50% its wt. of MeOH. Cf. C. A. 9, 1114, 1282.

Brit., 28,929, Dec. 15, 1913. W. K. FREEMAN. In the manuf. of fiber for spinning or paper-making purposes from wood and other vegetable substances, especially pinaceous or resinous wood, and the extn. of such substances as oil of turpentine and resin therefrom, the materials, such as wood chips, are subjected to 3 digesting operations in a digester in an atm. of H_2S . Sulfite, sulfate, soda, or other usual reagents may be used. A weak soln. is used for the 1st digestion, and oils and other volatile materials that are vaporized are condensed in a condenser and collected in a separator, from which the oil, etc., can be drawn off into a receptacle. At the same time, the gums, oleoresins, starches, acids, and much of the coloring-matter are extd. The soln. is then circulated through the app. by a pump and eventually returned to one of a series of selectors. A stronger soln. from a pipe is then introduced, and the pectose and intercellular matter extd. The liquid is again passed through the condenser and separator to another selector. The fibers in the digester are then treated with a soln. of intermediate strength, which, after the removal of gums, resin, etc., effects the cleansing

and bleaching expeditiously. The liquid is returned to the selector to be used for another operation. H is supplied from a holder which may be attached to the system. H is stated to exert a direct chem. action on certain constituents of vegetable substances; it also eliminates O and prevents discoloration. The digester may be heated by means of a steam-jacket, or by a steam-coil, and 1 or more digesters may be used. A H_2O -seal prevents ignition of the H. A 2nd condenser may be provided. By proper arrangement of the valves, the app. may be worked in a closed circuit, the liquid being circulated by a reversible pump.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Primer on explosives for metal miners and quarrymen. C. E. MUNROE AND C. HALL. Bureau of Mines *Bull.* 80, 125 pp.(1915).—While a popular exposition there is assembled here and reduced to application results of researches of the Bureau appearing in prior publications, information from remote sources, and results of some tests and investigations not before published. Special emphasis is given to the production of poisonous gases and the menace from them even in work in the open.

CHARLES E. MUNROE.

Piercing versus explosive shells. *Proc. U. S. Nav. Inst. Prof. Notes* 41, 560-1 (1915).—Various foreign nations have tested and rejected externally applied explosive shells of the Isham type. Large orders are now being shipped to belligerents, but all are of the armor-piercing type. This is an important commentary in the controversy as to the relative efficiencies of these explosive containers. CHARLES E. MUNROE.

Coal dust explosions. J. D. MORGAN. *Colliery Guardian* 109, 593-4(1915); *Iron Coal Trades Rev.* 90, 398-9(1915); cf. *C. A.* 8, 3629.—M. questions the validity of the Home Office Committee's report on coal dust explosions. He shows that explosions in a smooth gallery, such as was used by the committee, are less violent than those in constricted mine passages. Furthermore, it is impossible to establish a standard of inflammability that is independent of the source of ignition. H. L. OLIN.

Explosion at factory of Schultze Co. C. A. DESBOROUGH. *Home Office Rept.* No. 212, 4 pp.(1915).—The explosion was caused by accidental ignition of nitro-lignin residue in an abandoned iron boiler formerly used for the purification of the nitro-lignin by boiling. The boilers were being dismantled for removal and the workman inside had a steel bar and nails in his boots either of which may have struck sparks. The coroner's jury held that the boilers should have been thoroughly wetted down before wrecking operations began. CHARLES E. MUNROE.

MARSHALL, A.: *Explosives, their Manufacture, Properties, Tests and History.* London: J. & A. Churchill. 624 pp. 24s.

U. S., 1,135,026, Apr. 13. F. KNIFFEN. Pyroxylin varnish is made by the use of a volatile solvent formed of equal amts. of $EtOAc$ and C_6H_6 . The varnish may contain up to 24 oz. of pyroxylin per gal.

U. S., 1,135,356, Apr. 13. R. G. CLYNE. Treating paper shot-shell cartridge tubes to render them resistant to moisture and fire. The tubes are first impregnated with gasoline or other volatile liquid and are then immersed in a H_2O - and fire-proofing mixt. containing paraffin which displaces the volatile liquid.

U. S., 1,135,792, Apr. 13. C. HARTMANN. Hexanitrodiphenyl sulfide. See *Brit.* 18,353, 1913 (*C. A.* 8, 2603).

Brit., 28,634, Dec. 11, 1913. BICKFORD, SMITH & Co. and W. N. B. SMITH. In mfg. electric blasting fuses, arranging the firing-wire in a hole passing transversely through the axis of the fuse, the hole being then surrounded by waterproofing comp., preferably enclosed in an outer casing. The hole aforesaid is preferably filled with suitable priming comp. before being closed.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Progress in the preparation and use of vat-dyes during 1914. FRANZ ERBAN. Vienna. *Färber-Ztg.* 26, 3-6, 17-21, 32-5(1915).—A review. W. F. FARAGHER.

Production of azo dyes on the fiber by means of naphthol AS. G. ULRICH. *Brünner Monatsschrift Textil-Ind.* 21; through *Chem. Zentr.* 1915, I, 406.—The use of naphthol AS, a substitute for β -naphthol introduced by Chem. Fabrik Griesheim-Elektron, is discussed fully. The product is designated as an arylide of β -hydroxynaphthoic acid. W. F. FARAGHER.

Production of white and red printed effects on indigo-bottomed goods. G. TAGLIANI AND G. AROSIO. Mailand. *Färber-Ztg.* 26, 1-3(1915).—Eighteen methods which have been used in practice for producing white and red illumination effects together on indigo grounds are tabulated. Four employ reserves and 14 red and white discharges. W. F. FARAGHER.

A new after-chrome process. E. GROSSMANN. *Färber-Ztg.* 26, 17(1915).—In the usual after-chrome process, over-oxidation results readily as is shown by inferior shades and by the presence of detectable decomp. products. By using AcOH alone in the dye-vat, and Na_2CrO_4 instead of $\text{Na}_2\text{Cr}_2\text{O}_7$, good results are obtained with dyes which are easily over-oxidized. In the case of carbonized wool, since the presence of H_2SO_4 which is not wholly removed by washing causes over-oxidation, an addition of $\text{NaC}_2\text{H}_3\text{O}_2$ is made. Wools dyed by this process spin well and the material is not injured appreciably. The process may be used with dyes such as Eriochromblack T. W. F. FARAGHER.

National (British) dye scheme. ANON. *Board of Trade Announcement* Jan. 29, 1915; *J. Soc. Chem. Ind.* 34, 133.—The proposal is to form a company for the manuf. of dyes and by-products, with government aid and additional grants from the government, not exceeding £100,000 for the promotion of research work. It is planned that the company shall remain British, and that a coöperative agreement be adopted between the producers and users of dyestuffs. L. W. RIGGS.

Importance of a consideration of the fiber proteins in the process of bleaching cotton. B. S. LEVINE. Providence. Brown Univ. *Science* 41, 543-5(1915).—Analyses were made of Texas cotton, the 12 samples representing the cotton at different stages of maturity, ranging from 14 to 38 days after flowering. N factors were detd. by the Kjeldahl-Gunning method, while the wax and fat factors were obtained by extrn. first with alc. and then with ether. These latter figures were not detd. before the 24th day after flowering on account of the large amount of tannin present. The % of N showed a general decrease from 2.23% in the 14-16 day stage to 0.182% in the 36-38 day stage. The % of combined waxes and fats remained nearly const. after the 26-28 day stage; shows that there was an even distribution over the fiber, that their increase is proportional to the growth of the fiber, and that these constituents are not phosphatides taking part in the growth. The N figures favor the assumption that the early and constant deposit of protein remains in the lumen in the form of insol. albuminoids and in the form of the alc.-sol. proteins. Some of this protein is utilized by the growing fiber, the

increase of the fiber accounting for the decrease in the % of protein. The lowest % (2.20) for waxes and fats from fiber taken directly from the field was much higher than the figure obtained by Hebden (1.41) (cf. *C. A.* 8, 3632) for fibers which had been manufd. into cloth. The mechanical removal of waxes and fats by the processes of cloth making shows that these constituents are deposited on the outside of the fiber and therefore have but slight influence in bleaching as compared to the remaining proteins.

L. W. RIGGS.

Inspection of raw silk before boiling-off and weighting. KARL HOMOLKA. *Limbach. Färber Ztg.* 26, 32(1915).—Lots of silk accepted for weighting should be examd. for the presence of soap and oils which have been added to soften the fibers preparatory to weaving, since the loss in boiling-off will consist not only of the normal loss (22.25%) but also that of the soap and oil (20% approx.). This can be controlled by an experimental boiling-off, or by a fibroin detn.

W. F. FARAGHER.

BEACALL, T., CHALLENGER, F., MARTIN, G., AND SAND, H. J. S.: **Dyestuffs and Coal-Tar Products: Their Manufacture, Properties, Tests, and History.** London: J. & A. Churchill. 624 pp. 24s.

BEACALL, T., CHALLENGER, F., MARTIN, G., AND SAND, H. J. S.: **Dyestuffs and Coal-Tar Products: Their Chemistry, Manufacture, and Application.** London: C. Lockwood & Son. 156 pp. 7s., 6d.

U. S., 1,135,043, Apr. 13. O. NEUBERGER. **Printing designs on textile fabrics by the lithographic process.** A reduction dye is finely ground with oil or varnish, printed in the fabric after preliminary treatment of the latter with starch paste containing Na_2CO_3 and hydrosulfite, and developed by steaming and also by use of additional reducing agent if necessary.

Brit., 28,250, Dec. 8, 1913. J. MATTER. **Purifying mercerization lyes by treatment with insol. natural or artificial silicates, without heating.** Suitable substances are kaolin, China-clay, pumice, talc., white bole, and silicate residues from chem. manufactures. These substances may be used together with gypsum or gypsum and lime. The powdered materials are stirred with the lye, which is then allowed to settle.

Brit., 28,294, Dec. 8, 1913. H. HEYMANN. **In treating wool cheeses, cops, etc., preparatory to warping, the yarn, which has been formed from wool dyes before spinning, is degreased in this condition by means of a volatile solvent and then warped or wound into the desired form for weaving as usual.** The volatile solvent is caused to percolate through or into the cop or cheese, etc., or it is forced into or through the cop, etc., and subsequently expelled centrifugally. The solvent may be further expelled by evapn. The app. is specified in 19,522, 1913 (*C. A.* 9, 529).

Brit., 28,500, Dec. 10, 1913. F. L. BERTLETT. **A cleansing composition for fibers, fabrics, or other goods of cotton, linen, or wool consists of a mixt. of Na_2CO_3 and glycerol.** Any suitable disinfecting, lathering, or bleaching agent may be added to the comp. The use of the comp. is stated to nourish the fiber, keeping it pliable, firm, and durable, however often it may be washed. Any alkali may be used, K_2CO_3 , being mentioned specifically.

Brit., 28,569, Dec. 11, 1913. H. LEVINSTEIN, J. BADDILEY and LEVINSTEIN, *Ltd.* **Disazo dyes** are obtained by combining the tetraazo compd. of an aminoaryl-acyldiamine of the benzene or naphthalene series of the general formula $\text{NH}_2\text{.Ar.} \cdot \text{CO.NH.Ar'.NH}_2$, with 2 mols. of resorcinol, *m*-aminophenol, *m*-phenylenediamine,

or a deriv. thereof, or with 1 mol. of 1 of these compds. and 1 mol. of any other component. The use of aminopyrazolones as end components is excluded. The products dye cotton orange, orange-red, reddish yellow, yellow, yellow-brown, etc., shades, which are rendered fast by after-treatment with HCHO.

Brit., 28,763, Dec. 12, 1913. E. GMINDER. Treating fibrous materials with ozone. See Ger., 272,525 (C. A. 8, 2805).

Brit., 28,910, Dec. 15, 1913. CHEMICAL WORKS, formerly SANDOZ. Primary disazo, trisazo, and tetrakisazo dyes are obtained by combining resorcinol in an alk. soln. on the one hand with 1 mol. of a diazosulfonic acid of the benzene or naphthalene series or of a diazo compd. of a monoazo dye from a diazo-sulfonic acid of the benzene or naphthalene series or an *o*-diazophenol and Clève's acids, and on the other hand with 1 mol. of an *o*-diazophenol or of a diazo compd. of a monoazo dye from an *o*-diazophenol and Clève's acids. The products dye wool in acid baths various shades of brown, which may be after-chromed.

Brit., 28,911, Dec. 15, 1913. J. E. MACILWAINE. Bleaching fiber, yarn, thread, cord, woven fabric, or other material by the reaction in the fiber or material of a bicarbonate on a hypochlorite, so liberating the active bleaching agent in the body of the fiber, etc. In an example, linen cloth is prepared as usual with a lime boil, followed by an alkali boil, and is then thoroughly washed and run through a soln. of NaHCO₃, squeezed, allowed to lie a short time for the reaction to take place, washed in H₂O, soured as usual with dil. H₂SO₄ or HCl, washed, and finally given an alkali boil. The process may be repeated as often as desired. Rollers, centrifuging, steam pressure, etc., may be used to press the bicarbonate and chloride solns. into the material, and these solns. may be used in the reverse order.

Ger., 279,492, Apr. 1, 1913. O. VENTER. Dyeing yarn loose and then winding it, more or less moist, on spools for weaving.

Ger., 280,366, Nov. 7, 1913. E. C. LEHMANN. Treating cloth, especially closely woven fabric, to increase its elasticity, by subjecting it for a short time to the action of hot bisulfite solns., washing in cold H₂O, and finally drying without tension. An approx. 5% soln. of NaHSO₃ is heated to b., and the material is immersed for several mins. and kept in motion in the hot soln. In the cold H₂O the temp. of the material is lowered rapidly, and the NaHSO₃ is removed by washing. The material is dried preferably at the ordinary temp. on short perforated shelves. The cloth is shrunk by this treatment, but is rendered very elastic.

Ger., 280,369, Mar. 27, 1914. Addition to 277,497 (C. A. 9, 866). A. HEINZEL, JR. Production of polychrome effects in fabrics. The alk. bath contains no oxidizing agent; the oxidation of the Ce compds. pptd. on the artificial fibers is effected either by the action of the O of the air, or with the aid of an oxidizing agent after the fabric has been made up. The fibers, which have been subjected to the action of the Ce prepn., are after-treated with vegetable or animal fats which are applied either saponified or unsaponified, in emulsion with alkalis, preferably together with the gelatin dressing. The fabric made up from the impregnated artificial fibers is developed at the lowest possible temp., *e. g.*, 20°.

Ger., 280,488, May 19, 1914. A. DIENER. In producing designs on fabric, the fabric is moistened or placed in a 5% starch soln. containing glycerol, before the wax is applied. A color may be incorporated, if desired, in the reserve.

Ger., 280,591, Oct. 26, 1913. METALLATOM G. M. B. H. App. for the production of metallic coatings on fabric, comprizing an atomizing nozzle upon which is mounted a removable heated chamber in which the finely divided material supplied by the atomizing nozzle is volatilized and expelled in this condition.

A. H. SABIN.

Foundations for a theory of pigments. I. Fundamental characteristics of pigments and the size of the granules. W. OSTWALD. Grossbothen. *Kolloid-Z.* 16, 1-4 (1915).—After calling attention to the lack of scientific method in the manuf. or study of pigments, O. suggests 3 fundamental properties according to which pigments should be classified: (1) Color, including 3 factors: the color tone, or location of the color on a circle consisting of the prismatic colors with the red and blue ends united by passing through purple; brightness or fraction of light reflected as compared with the amt. reflected from pure white under the same conditions; purity (a given color is a mixt. of a pure color with grey; the % of pure color is the purity). (2) Covering ability: the number of sq. cm. of surface that can be covered by 1 g. of the pigment so that the covered surface does not show through. (3) The strength of color, or the ratio in which color and white pigment may be mixed before the color is just gone. The size of the particles of the pigment affect the color; as examples are cited Fe_2O_3 , PbCrO_4 , and smalt. Covering ability is almost nil with crystals or transparent articles, but on grinding these up it becomes fairly marked. With decreasing size of particles the covering ability increases to a max. and then decreases. Strength of color also increases with decreased size of particles.

Lead acetate and basic acetate are obtained by blowing air through a soln. of HOAc or $\text{Pb}(\text{OAc})_2$, the surface of which is below the level of a heap of Pb, so that the liquid is carried upwards and sprinkles the Pb in its descent. Cf. *C. A.* 8, 2497.

Brit., 29,161, Dec. 17, 1913. J. P. ELLIOT. An anti-rust composition, for preventing rusting or oxidation of bright metallic surfaces, consists of a mixt. of 3 to 6 oz. of oleic acid, 0.5 to 2 oz. of stearic acid, 2 drams of $(\text{HOCO})_2$, and 1 gal. of a solvent

which may be benzene, mineral naphtha, benzine, petrol, etc. The $(\text{HOCO})_2$ is dissolved in rectified spirit of wine and added to the other ingredients dissolved in the solvent.

Fr., 466,304, Dec. 6, 1913. STANDARD LACK- UND FARBWERKE ZÜRICH-ÄLTSTETTEN. An easily removable anti-rust paint is prepd. by combining aq. solns. of chromic acid, chromates, carbonates, milk of lime, etc., with hydrocarbons, fats, oils, resins, clay, chalk, to form an emulsion.

Fr., 466,368, Dec. 18, 1913. G. PATERNO and C. MANUELLI. Fluorides or fluosilicates of Al, Zn, Pb, etc., are added, up to 40-50%, to paint for ship bottoms.

Ger., 280,841, Feb. 11, 1914. A. PADBERG. A documentary ink, such as the Fe tannates, is made up in gum arabic capsules with a view to protecting the hands and at the same time providing the necessary thickening agent when taken up in soln.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Catalytic addition of hydrogen to unsaturated substances. Formation of metallic nickel in hardening oils with aid of nickel oxide and other nickel compounds. W. NORMAN AND W. PUNGS. *Chem. Ztg.* 39, 29-31, 41-2(1915).—One hundred g. of various unsatd. oils were hardened in 2 to 3 hrs. by H (2 l. per min.) in presence of the oxide, hydroxide, carbonate or formate of Ni (1 g.) at a temp. between 200 and 255°. The formation of the metallic Ni during the process was detd. by an elec. cond. method, a magnetic method and 2 analytical methods, depending, resp., upon the amt. of H evolved with H_2SO_4 and the production of Ni carbonyl. Although the carbonyl reaction is not quant. it gives reliable qual. results at 30, 50 and 90°, but in each case air must be excluded. Under these conditions at 225° NiO is not reduced by CO, benzaldehyde or formaldehyde. The catalyst averaged from 4 to 7% of metallic Ni. Rapid hardening can also be effected with kieselguhr contg. 4.1% Ni which has been reduced at 500°.

E. SCHERUBEL.

Nickel borate as fat hardening catalyzer. W. NORMAN. *Seifensieder Ztg.* 42, 46-7(1915).—The view of Schönfeld, that Ni borate when heated in a stream of H undergoes no change and that the salt is active catalytically, is incorrect. The salt is decomposed into metallic Ni and H_3BO_3 . S. makes the statement that as soon as hardening can be detd. metallic Ni can be found in the catalyzer.

E. SCHERUBEL.

Detection of sea animal oils. A. GRÜN AND J. JANKO. *Seifenfabr.* 35, 253-4 (1915).—The authors applied the test of Tortelli and Jaffe (cf. C. A. 8, 3723) to a number of oils and did not find it to work in all cases. Green linseed oil gave the same reaction and a number of com. fish oils did not, without being previously purified with fullers earth. Incompletely hardened fish oils and their fatty acids gave the reaction even when present in small amt. in a fat mixt. The fatty acids in soaps without having had previous purification and in presence of rosin give the test. Completely hardened sea animal oils do not respond to the test.

E. SCHERUBEL.

Factory control in the soap, fat and glycerol industry. H. STADLINGER. *Seifenfabr.* 34, 680-1, 718-21, 779-81, 809-11, 837-9, 890-2, 1138-40, 1160-2, 1184-6, 1227-9, 1248-50, 1301-2(1914).—This article deals with the av. values of the consts. found for many fats, oils, fatty acids, soaps and washing powders.

E. SCHERUBEL.

Brit., 28,261, Dec. 8, 1913. HARBURGER-EISEN- UND BRONZEWERKE AKT.-GES. and G. KÖRBER. In the treatment of oil-meal or grain residues, from which oil has

been extd. by solvents such as benzine, trichloroethylene, etc., with steam to remove the final traces of solvent and to moisten the meal, the steam is passed through 2 or more extractors, the pure steam being passed into the extractor containing only a small amt. of solvent. The steaming may be carried out in app. of the kind described in 27,014, 1913 (C. A. 7, 1402).

Brit., 29,122, Dec. 17, 1913. C. PLEINES. Perfectly neutral soaps are improved by incorporation of hydrocarbons. In an example, a mixt. of tallow, linseed oil, horse fat, palm oil, and resin is saponified, and 5% of benzine is mixed in when the temp. has fallen to below 100°. Superfatted soap with incorporated hydrocarbon, such as is described in 24,795, 1913 (C. A. 9, 1257) is disclaimed.

Ger., 280,688, June 6, 1912. H. and O. OCKELMANN. A cleaning composition, such as specified in 259,360 (C. A. 7, 3000), is converted into the form of a solid soap. The added sugar must exceed many times the amt. of alkali in the soap. E. g., a soap may be used which consists of 40 parts fatty acids, 10 caustic alkali, 25 sugar or the like, and 25 H₂O. In place of sugar, starch sugar, sirup, molasses, and the like may be employed. Cf. C. A. 8, 3632.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Physical and chemical nature of the natural gums. H. RAZMAN. *Farben-Ztg.* 20, 639-40, 667-9(1915).—A general article. E. W. BOUGHTON.

Gum arabic. ALLAND. *Bull. des Sc. Ph.* Aug.-Sept. 1914; *Schweis. Apoth. Ztg.* 53, 31-2(1915).—An account of the origin, collection and commerce of gum arabic in Egyptian and French Soudan and on the Senegal river. S. WALDBOTT.

U. S., 1,135,216, Apr. 13. F. W. SPANUTIUS. Making a decolorizing material for treating sugar solutions, etc., by dissolving argols in NaOH to destroy the coloring matter, adding KCl, filtering off the bitartrate soln. and carbonizing the solid residue.

U. S., 1,136,613, Apr. 20. M. M. RAUB. Chewing-gum formed of chicle 1, sugar 3, pine tar 0.16 part and additional flavoring as desired, e. g., oil of peppermint.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Contributions of the chemist to the leather industry. W. H. TRAS. *J. Ind. Eng. Chem.* 7, 283(1915). ISADOR MILLER.

The theory of leather formation. W. FAHRION. *Collegium* 1914, 707-10.—Reply to Powarnin (cf. C. A. 9, 977), whose criticisms are rejected on the ground that he does not know F.'s recent publications. L. B.

Changes in the appearance of natural and artificial leather. K. MICKSCH. *Kunststoffe* 5, 78-80(1915).—A general discussion of the subject. The changes are mainly mechanical. F. W. SMITHER.

The adulteration of leather. J. A. S. MORRISON. *Leather World* 7, 127-8(1915).—It may be safely stated that 50% of bottom stuff offered for sale is adulterated in some way. In some cases Epsom salt and glucose are added, as such, in amts. of from

4 to 10%. In other cases they are added more cleverly through exts. which are adulterated. These exts. are made solely with the object of producing leather which will just pass the I. A. L. T. C. limits (2 to 3%). M. thinks that such practices should be stopped.

J. S. ROGERS.

Addition of fat to tanning extracts. P. SINGH. *J. Soc. Chem. Ind.* 34, 208-9 (1915).—S. finds that the quality of leather is affected by addition of fat to the tannin-liquor; materials which otherwise make harsh leather may thus yield a tough and supple product.

L. B.

Tanning power of triacetin. PIETRO FALCIOLA. *Ann. chim. applicata* 3, 32-6 (1915).—The expts. were made upon skins of calf, lamb and sheep that had previously been depilated, swelled, then cleaned and washed. Triacetin alone imparts marked tanning effects after a few hrs. immersion without agitation, and does not make the skin brown. A certain amt. of tanning is caused by a simple short brushing of the triacetin upon the skin. A 10% aq. emulsion of triacetin tans in 5 hrs.; a 7% soln. tans almost completely in 5 hrs. Increased diln. of the soln. causes the skin to become parchment-like and stiff, while it becomes softer with increase of conc. H₂O-EtOH-triacetin solns. of the strengths 100:3:3, 100:6:6, 100:33:33, gave good tanning effect with skin of lamb after 4 hrs., the last strength giving the best results; very weak solns. impart a degree of stiffness to the skins. Lamb skin weighing 23 g. immersed for 24 hrs. in 100 g. H₂O contg. 2.15 g. triacetin, absorbed 0.23 g. triacetin, or 1%.

S. LEVY.

Wattle bark for tanning. ANON. *Hide and Leather* 49, 24(1915).—The av. amt. of tannin in com. wattle bark is 32%. In Germany it is chiefly used for heavy leathers, but it might well be used for light leathers as it furnishes a full soft leather with calf skin. The leather has a faint reddish tinge which darkens slightly on continued exposure to light. Wattle ext. is soon to be manufd. in Natal.

J. S. ROGERS.

Chestnut extract. L. POLLAK. *Collegium* 1914, 715-6; cf. *C. A.* 9, 979.—On extg. with NaOH and pptg. with alc., an alk. gummate is obtained, which may be decompd. with HCl, yielding from 5% to 8% of xylan.

L. B.

Chrome soap in chrome leathers. G. HUGONIN. *Collegium* 1914, 716-7.—H. found that chrome soaps are sol. in benzine. On extg. chrome leather with benzine and evapg. the soln. the ash was free from Cr. H. concludes that the fat-liquoring of chrome leather does not make Cr soaps in the leather.

L. B.

A bacteriological study of methods for the disinfection of hides infected with anthrax spores. F. W. TILLEY. *J. Agr. Res.* 4, 65-92(1915).—The Seymour-Jones method which recommends the use of HgCl₂ (0.04%) and HCOOH (1%) for the disinfection of hides infected with anthrax spores, and the Schattenfroth method which involves the use of HCl (2%) and NaCl (10%) were both found to be efficient. The treatments exert no injurious effect upon the hides or leather.

J. J. SKINNER.

Apparatus for the extraction of glue. G. BARNICK. *Leipzig. Chem. App.* 2, 75-8(1915).—The arrangement of the app. is shown in 4 cuts, and general directions for operating are given.

J. H. MOORE.

Borax and Boracic Acid in Leather Manufacture. London: Borax Consolidated, Ltd. 92 pp.

U. S., 1,135,977, Apr. 13. L. E. LEVI. **Tanning hides by immersion in a soln. of basic ferric chromate or sulfochromate.**

U. S., 1,136,456, Apr. 20. F. E. WOODWARD. **Plastic filler for use in shoe-bottoms, formed of Burgundy pitch 450, red engine oil 60 lbs. and about 25 lbs. of**

sawdust, granulated cork or leather for every 6 gals. of the pitch and oil mixt., mixed with about 10 lbs. of NaHCO_3 which serves as a fire-proofing agent.

U. S., 1,136,457. Apr. 20. F. E. WOODWARD. Plastic shoe-bottom filler formed of resin 250, vaseline 30, pine tar 20, NaHCO_3 10 lbs. and 25 lbs. of sawdust, cork or leather for every 6 gals. of the mixt.

U. S., 1,136,458, Apr. 20. F. E. WOODWARD. Plastic shoe-bottom filler formed of wax tailings 240, resin 240, petroleum oil 80, NaHCO_3 10 lbs. and 25 lbs. of sawdust, cork or leather for each 6 gals. of the mixt.

U. S., 1,136,459, Apr. 20. F. E. WOODWARD. Plastic shoe-bottom filler composed of pontianac resin 4, resin oil 4, resin 16, pine tar 1, solid petrolatum 8, and NaHCO_3 10 lbs., and 25 lbs. of cork, leather or sawdust for every 5 gals. of the adhesive mixt. Cf. C. A. 9, 394.

Brit., 28,453, Dec. 10, 1913. G. H. TATHAM, D. R. BLAIR, C. T. WESTWOOD and J. H. DUNKIN. Gelatin is obtained from fish bones and subsequently treated to obtain modifications thereof. The cleaned bones first have their outer hard covering softened by soaking in H_2O , preferably constantly renewed, and the Ca phosphate, Ca carbonate, etc., is dissolved out by adding alkali or acid, preferably K silicate or HCl , to the H_2O to make a 10% soln. Alternatively, the clean bones may be extd. with HCl and K silicate added to the product. The bones are then digested in a steam-jacketed vessel containing a very dil. soln. of KHCO_3 . The steam having been allowed to escape slowly at the completion of the digestion, the pan is opened, and the mass of viscid gelatin found at the bottom removed. By adding pure gelatin, preferably in sheets, to the mass, clear gelatin collects on the sheets and is removed, leaving a dark colored gelatin which is less sol. in H_2O . The latter gelatin is then purified in any usual way, as with fullers earth, kaolin, or China-clay. The clear gelatin is worked into any desired form and rendered insol. by treatment with HCHO vapors, or by the addition of tannic acid, which renders it sensitive to light, so that it becomes dark in color and insol. in H_2O , the product being miscible with transparent and suitably colored gelatin forming imitation tortoise shell.

Ger., 279,421, Mar. 1, 1914. A. JUNGFER. Mfg. corset stays, and the like, from leather, cut to size and impregnated with resin, varnish, or the like, to render the material impervious to moisture and to strengthen it.

Ger., 280,330, Feb. 17, 1914. A. GROTHE GEB. SODENDORF. Process of mfg. a tanning agent from sulfite cellulose back water, by means of which the organic S, as well as the gums and other carbohydrates, are sepd. from the tanning material. The free SO_2 of the back water is removed first by the addition of lime. The residual liquid is analyzed, and the S content, especially, is detd. For every 32 parts by wt. of organic S, 65 parts of KCN (or its equiv. of another cyanide) are added in conc. aq. soln. The mixt. is heated in an autoclave for 4-5 hrs. at about 150° under a pressure of about 5 atms. After cooling, the mass is drawn off into a vessel, dild. with H_2O , and allowed to stand for 24 hrs. At the end of this period the insol. constituents have settled; the clear supernatant liquid is drawn off, and the insol. residue is washed out. The residue consists essentially of neutral CaSO_3 , and can be utilized in the cellulose manuf. The liquid is acidified with HCl or H_2SO_4 , whereupon a copious brownish ppt. seps.; this consists of an organic cyanogen compd. The ppt. is sepd. from the liquid, washed with H_2O , and dried at the ordinary temp. It is rather insol. in the mother liquor which contains the gummy matter, carbohydrates, and sugars, as well as the inorganic salts and traces of CN-compds. The aq. soln. of the sepd. ppt. is a valuable tanning agent, pptg. gelatin, glue, pancreatin, etc., and being taken up completely by animal skin. The best result is secured by using a freshly prepd. aq. soln. of CaNCN

as the CN compd. Addition of CaCl_2 and NH_4Cl increases the yield of tanning materials. If the mixt. is found to contain free HCN at the ordinary temp., alkali must be added.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Rubber chemistry in 1914. R. DITMAR. *Kolloid-Z.* 16, 39-53(1915).—A review. W. F. ZIMMERLI.

Specifications and methods of analysis for mixtures containing thirty per cent of hevea rubber. ANON. *Caoutchouc & gutta-percha* 12, 8587-92(1915).—A continued article in which the conclusion is drawn that the analysis should include appropriate tests of elasticity and mechanical resistance to show whether the vulcanization has been done properly, and also tests of elec. resistance to insure good insulation and a homogeneous structure. EDWARD J. KELLEY.

Recommendations for the treatment of latex and the curing of rubber. RUBBER GROWERS ASSOC. *India Rubber World* 52, 374-5(1915).—An outline of the proper conditions which should obtain in the collection and coagulation of latex, and in the creping, sheeting and smoke curing of plantation rubber. Possible contaminations and deteriorating factors are pointed out, and methods of preventing these are indicated in the form of mandatory instructions to plantation employees. R. T. S.

Examination of litharge (BECK) 7.

TORREY, J. AND MANDERS, A. S.: *The Rubber Industry*. London: 516 pp. 15s., 6d.

U. S., 1,135,236, Apr. 13. O. A. WHEELER. Reclaiming vulcanized scrap rubber containing cellulose by pulverizing the scrap, allowing it to stand for 3-5 hrs. in a 20% soln. of NaOH, then adding CS_2 , agitating 1-5 hrs., adding H_2O and heating under 100 lbs. pressure per sq. in. for 15-20 hrs.

U. S., 1,136,462, Apr. 20. C. P. BARY. Purifying caoutchouc by dissolving in C_6H_6 , CS_2 , CHCl_3 or other solvent and dialyzing through a caoutchouc membrane against pure solvent. The liquids are circulated on both sides of the membrane. Solns. of acetylcellulose may be similarly purified.

Brit., 28,938, Dec. 15, 1913. J. G. WARDROP and C. C. STEPHEN. A machine for washing and masticating scrap rubber and similar substances comprizes an internally toothed U-shaped receptacle in which is eccentrically mounted a toothed rotary drum or disks, so that, as the rubber progresses around the drum, etc., it is subjected to increasing compression. The hinged lid is weighted and is perforated to allow light impurities to escape with the overflow H_2O , while heavy impurities pass through perforations in the lower portion of the receptacle. The receptacle is mounted on trunnions so that it can be tilted.

CHEMICAL ABSTRACTS

Vol. 9.

JUNE 20, 1915.

No. 12.

I. APPARATUS.

L. C. JONES.

Quartz-glass apparatus. P. A. Z. *Elektrochem.* 21, 165(1915).—The note concerns the use of quartz stop-cocks and funnels. F. A. HARVEY.

Laboratory steam drying oven. L. E. LEVI AND A. C. ORTHMANN. *Collegium* 1914, 741-3.—A new form of steam oven is described, with diagrams. L. B.

Acid siphon. WILHELM SZIGETI. *Brasso. Chem. Ztg.* 39, 122(1915).

J. H. MOORE.

Economic operation of electric ovens. P. W. GUMAER. *Proc. Am. Inst. Elec. Eng.* 34, 1001(1915). C. G. F.

Electrically operated centrifuge. ANON. *Elec. World* 63 1131(1915).—This app. is compact, low-set, and is equipped with a weighted fly-wheel which serves to steady the action of the motor and to maintain a uniform but high speed. It is also provided with a 2-arm sedimentation attachment and a speed controller. For obtaining the count of red corpuscles in a certain amount of blood, a Daland hematocrit is used in conjunction with the centrifuge. A diagram is given. I. C. MATTHEWS.

Micro-balance. E. H. RIESENFELD AND H. F. MÖLLER. *Z. Elektrochem.* 21, 131-6(1915).—By the use of quartz torsion fibers the difficulties due to knife edges are avoided. This principle has already been used by Nernst and Riesenfeld (cf. *Ber.* 36, 2086(1903)). A very fine quartz fiber, 0.0125 mm. in diam. and 9 cm. long, is stretched horizontally between the prongs of a brass fork. Cemented with hard shellac to the center of the fiber is a glass capillary, 13 cm. long and weighing 78 mg. This glass "beam" is set at an angle of about 25° with the horizontal. It ends in a fork at the upper end and has a mirror (wt. 180 mg.) made from a quarter of a specially ground microscope cover-glass, cemented to its lower end. The beam is supported 3 cm. from the mirror. The great sensitiveness, and particular improvement, of this balance is due to the method of supporting the scale pan. Between the prongs of the fork at the end of the beam is stretched, horizontally, a piece of the fine quartz fiber. Between this fiber and the hook of the scale pan another quartz fiber, 0.04 mm. diam., is inserted. Thus the support of the scale pan depends on torsion and not on a knife edge of any kind. The scale pan weighs 17 mg. The load at the scale pan may be varied by hanging pieces of Pt on a hook just above the scale pan. The beam is arrested by clamping it near its upper end between 2 fine feathers. Deflections are detd. by telescope and scale. Details of the balance mounting and case are given. Some exptl. results are given which show the max. load to be 5×10^{-3} g. and the minimum wt. which can be detected with certainty 3.3×10^{-3} g. F. A. HARVEY.

A vacuum furnace for the measurement of small dissociation pressures. R. B. SOGMAN AND J. C. HOSTETTER. *J. Wash. Acad.* 5, 277-85(1915).—This paper describes a vacuum furnace and accessory app. adapted for the measurement of a wide range of dissociation pressures of Fe oxides and silicates. The furnace consists essentially of 2 parts: (1) the furnace tube, which serves both as the furnace wall enclosing the "inside vacuum" and as the heating element; (2) the water-cooled jacket which

surrounds the furnace tube and encloses the "outside vacuum." The furnace tube is 10 mm. inside diam. and made of an alloy of 80 parts Pt and 20 Rh. Three gages provide a possible range of pressure measurement from 0.000001 mm. Hg up to 2.5 atms. The uniformity of temp. was tested by taking a series of measurements of the O pressures produced by 0.5 g. charges of Fe oxide, heated at various levels in the furnace. These indicate a length of about 25-30 mm. within which the temp. is uniform within one degree. The furnace takes 580 amps. at 1.8 v. at 1450°, and can be held const. to one degree at this temp.

L. H. A.

Convenient apparatus for chlorination with phosphorus pentachloride. STUART P. MILLER AND FRANKLIN C. GURLEY. *J. Am. Chem. Soc.* 37, 1361(1915).—If the chlorination product is not volatile, the material to be chlorinated is placed in the bottom of a suction filter flask, the side tube connected to the pump, the PCl_5 added and the substances ground together with a heavy glass rod; all the fumes are drawn away by the pump, making the use of a hood unnecessary.

CHAS. A. ROULLIER.

Potentiometrical arrangement for electrochemical research. O. SCARPA. Napoli. *Ann. chim. applicata* 3, 157-61(1915).—Resistance boxes with units so arranged that the resistance can be varied from 1 to 10,000 ohms are used. In the figures there are shown: a battery of Pb accumulators (E), a capillary electrometer or galvanometer (G) sensitive to 0.0001 volt, a standard cell (e), a commutator (c), a resistance of about a megohm (R). This resistance is made by bending a capillary tube as in Fig. 3, each end being terminated by a wider tube which is closed tightly by a stopper carrying a Cu wire dipping into a soln. of CuSO_4 acidified with H_2SO_4 . If

FIG. 1

FIG. 2

FIG. 3

ρ is the sp. resistance of the soln., l the length of the capillary tube, d its diameter, then the resistance is $4\rho l/\pi d^2$, and placing this $\approx 10^6$ ohm, it is easy to calc. the necessary concn. of the soln. This resistance remains const. for a long time (3 years in 1 case). Fig. 2 shows the arrangement of the compensated circuit; (A) and (B) are the levers of the 2 decade boxes. The e. m. f. of the battery must be greater than the p. d. to be measured. The current is sent through the system as arranged in Fig. 1, the contacts (C)

and (T) are open, and (S) closed, while the plugs in (M) are all in, and those in (N) all out, and the levers (A) and (B) are at zero. The contact (C)-(e) is made, and (A) and then (B) moved to cause the least deviation of the galvanometer; close (T) and bring the instrument to zero, taking out the proper plugs in (M) and at the same time putting in the corresponding plugs in (N) so as not to alter the total resistance of the circuit. The value γ_c of the compensating circuit based on the compensated circuit between (A) and (B) is obtained by adding the values

at the points of contact of (A) and (B) and of (M). Opening (C)-(e) and closing (C)-(x) the same operation is repeated on the unknown e. m. f. and the new resistance γ_x obtained in the same manner as before. If the standard cell is a Weston, then $x = 1.019 \gamma_x / \gamma_e$ volts. The advantage of this arrangement over the usual compensating methods is that it allows of much more rapid measurements (especially necessary in detg. e. m. fs. of polarization), and also much more exact, as the momentary variation of resistance of the compensating circuit during regulating is always very small, the current of the battery remaining thus perfectly const. The method has greater sensibility than that of Oswald as 0.0001 volt can be measured when working with e. m. f. of less than 2 volts, and also greater precision, as the battery current required is very much less. The system permits measurements of between 10 and 0.0001 volt.

S. LEVY.

A new machine to test oils and friction metals at all temperatures. ANON. *Mat. grasses* 8, 4279-86(1915).

Brit., 29,392, Dec. 20, 1913. A. RÖMER. In an annealing vessel having a chambered cover containing absorbent material, vents are provided which are open to allow gases to escape from the vessel through the absorbent material during the annealing process and are closed during cooling to exclude air.

Brit., 129, Jan. 2, 1914. A. WILLIAMS and L. D. WILLIAMS. An app. for indicating the proportion of combustible gases in air comprizes a thermo-elec. circuit in which 1 junction is in proximity to a catalytic substance, such as finely divided Pt, and both hot and cold junctions are equally heated to maintain the catalytic substance in active cond. without affecting the thermoelec. current.

Brit., 250, Jan. 5, 1914. J. HARGER. An app. for estimating substances in gases or liquids consists of a small primary cell containing the liquid to be tested, and a galvanometer connected to the electrodes of the cell. The gas is passed at a regulated rate into liquid allowed to drop into the cell. Automatic means may be provided for recording the reading of the galvanometer needle. When using the app. to estimate the amt. of CO in the gases of mines, they are passed through Br water, KOH, H₂SO₄, or P₂O₅, and then over heated I₂O₅, whereby the amt. of I equiv. to the CO is sepd. This I is then converted into acid by treating with amorphous P or arsenious acid soln., and the soln. so obtained run into the cell. The tube containing the I₂O₅ is conveniently fitted into the space between the gauze and the bonnet of a miner's safety lamp, and

may be protected from the direct heat of the lamp by a bath of CaCl_2 soln. SO_3 , nitric fumes, and SiF_4 are estimated by passing into H_2O flowing into the cell; Cl by passing into arsenious acid soln.; fire-damp by passing through Br water, and then a heated tube to form HBr and dissolving this acid; O by passing over S or P and dissolving the acids formed in H_2O . If large quantities are to be estimated, the cell should be adjustable so that the distance between the electrodes may be varied. An audible alarm may be connected to the galvanometer.

Brit., 367, Jan. 6, 1914. J. T. BATEMAN. An app. for deodorizing vegetable, fish, and like oils and for distilling and vaporizing liquids, wherein the liquid is treated with steam or other vaporous or gaseous heating-medium, with or without a preheater for the liquid.

Ger., 279,868, Aug. 24, 1913. C. W. BAUMANN. Horizontal-tube condenser in which the cross-section of the cooling tubes increases in the direction of flow of the cooling agent.

Ger., 281,137, Feb. 7, 1913. F. A. BÜHLER. App. for effecting chemical reactions, or physical reactions. The wall d of a shaft a , to which the material to be acted upon is supplied through the channel b , is surrounded by a cylindrical chamber, c , a 2nd wall, e , a 2nd cylindrical chamber, f , and a 3rd wall, g . Perforations are formed in the walls d and e , designated by h and i , resp.; these are inclined downwardly into the cylindrical chamber c . The substance which is used to effect the reaction is charged through the throat k into the chamber c ; by force of gravity it fills this chamber and may be removed at m readily, passing down the inclined plane l . The chamber c is enlarged at the bottom, conically, as shown. The material under treatment is carried off through the exit tube n . E. g., if H_2O is to be purified, gravel is introduced at k , the H_2O enters at b , rises in the shaft a , passes through the perforations h , through the gravel, through the perforations i , into the chamber f , and out at n . The app. may be duplicated to form batteries. Gas may be purified or dried in this app., and chem. reactions may be effected.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Atoms and ions. J. J. THOMSON. *Engineering* 99, 329-30, 356-7(1915); cf. *C. A.* 9, 1412.—Certain salts when heated gave off positive electricity, others negative. When AlPO_4 was heated under a plate held over the heated salt and connected to an electroscope, the electroscope was discharged if its own charge was negative, but not if its charge was positive. The same kind of electricity was given off when the salt was ground in an agate mortar. To det. e/m for the carriers present, 2 plates d cm. apart were prepd., on one of which the salt was placed, and the other of which was connected to an electroscope. Between the plates and parallel to them a strong magnetic field was established. Carriers from the salt reached the other plate when there was no magnetic field, but were bent back when the field was established. An idea of the nature and size of the particles was obtained from the equation: $d = 2(X/H^2)(e/m)$,

where X is the elec. force urging the particles from one plate to the other, and H the strength of the field. For K or Na salts the carriers were nearly always atoms, as shown by the (e/m) values. Cases where the electrification arose from the salt (ZnI_2 , $ZnBr_2$, and CdI_2) were considered (cf. Kalandyk, *C. A.* 9, 11). When air was pumped through a tube and over a wire connected to the electroscope, there was a loss of charge corresponding to the production of 4 ions per cc. per sec., and this was found in air from all parts of the world, independent of temp., the nature or size of the vessel in which the cond. was measured, or the pains taken to exclude radiations by Pb walls etc. Air might have more ions than this, but in no way was it possible to reduce them below 4 per cc. per sec. Decrease of resistance of vaseline contg. Br , of C_6H_{14} , or Se cells when exposed to Röntgen radiations was also mentioned. E. B. MILLARD.

Eighth group of the periodic system. E. H. BÜCHNER. Amsterdam. *Chem. Weebblad* 12, 336-9(1915).—The conception of isotopic elements is made use of in grouping together, in one place in the periodic table, elements which show close chem. relationships. E. g., Mn , Fe , Co and Ni are grouped together as ZFe ; Ru , Rh and Pd as ZRu ; Os , Ir and Pt as ZOs ; and the trivalent and tetravalent rare earths in 2 groups, ZR^{+++} and ZR^{++++} , resp. The 8th group in B.'s table consists of the halogens and the groups of "isotopes," ZFe , ZRu , ZOs , the latter groups occupying a place in the 8th group similar to that in which Mn is usually placed. GEORGE W. MORREY.

Chemically active modification of nitrogen produced by the electric discharge. VI. R. J. STRUTT. *Proc. Roy. Soc. London (A)* 91, 303-18(1915); cf. *C. A.* 8, 1695, 2283-4, 3257.—The past controversy as to whether active N can be freely obtained from pure N or whether a trace of O must be present has been reviewed. It is shown that neither alternative is correct; perfectly pure N will not give more than a little active N , but to get a good yield it is not necessary that O or any O compd. be present. The admixt. of almost any foreign gas in small amt. will enormously increase the yield of active N . The amt. required is generally about 0.1%, but a very distinct effect was produced by the addition of 0.003% of CH_4 . The impurity possibly acts by loading the electrons and thus altering the character of their impact with the N mols. This is supported by the fact that gases carrying O , S , Cl , C and H are capable of promoting the formation of active N . These atoms are capable of attaching themselves to electrons, as shown by Thomson and Franck. A , He , and, of course, N itself, which are not able to load electrons, do not promote the formation of active N . Active N when shaken with cold Hg unites with it, forming a nitride, but no development of the Hg spectrum attends the action, as when Hg vapor unites with active N . Similar results have been obtained with other melted metals. Active N when bubbled through a soln. of indigo in H_2SO_4 slowly discharges the blue color. It acts freely on the purest C_6H_{12} and C_7H_{14} obtainable, with the formation of HCN . On CH_4 the action was less, though considerable. These expts. do not bear out the view that it is only olefin impurities in paraffins that can yield HCN . E. B. MILLARD.

Molecular attraction. XI. New relations revealed by diagraming internal pressure as a negative pressure. J. E. MILLS. *J. Phys. Chem.* 19, 257-74(1915); cf. *C. A.* 7, 7; 8, 1527.—The thermodynamic equation for the energy spent in overcoming the external pressure during change of vol. can be combined with the Clausius-Clapeyron equation to give $P(V - v) = (dP/dT)T(V - v) - 31414 L$, where P is the external pressure, V the vol. of a gram of vapor, v the vol. of a gram of liquid, and L the "internal heat of vaporization," i. e., the difference between the total heat of vaporization and the energy spent in overcoming external pressure. The data of Young on isopentane are used in the discussion. When the term $(dP/dT)T(V - v)$ is represented on a PV plane, the pressure ordinate is enormously greater than P and must be extended into the region of negative pressure or as a positive pressure far greater

than we have any evidence to support. The neg. pressures are average internal pressures during a given change in vol., except at the crit. temp. At this temp. there is no change in vol., and the "average" neg. pressure above should represent the true internal pressure at this vol. This conception is discussed. E. B. MILLARD.

Relativity theory: General dynamical principles. R. C. TOLMAN. Univ. Calif. *Phil. Mag.* 28, 572-82(1914).—Taking into account the Einstein theory of relativity, the principles of the conservation of momentum, and of the conservation of moment of momentum are derived for a system of particles, and also a principle corresponding to that of least action which applies in ordinary mechanics; this leads to generalized equations of motion in the Lagrangian and Hamiltonian (canonical) forms. It is found that the Lagrangian function is not to be taken equal to the difference between the kinetic and potential energies of the system as in the classical mechanics, and the generalized momenta used in the modified Hamiltonian equations are not to be defined as the partial differential of the kinetic energy with respect to the generalized velocities as in the older mechanics. A. T. CAMERON.

Relativity theory: The equi-partition law in a system of particles. R. C. TOLMAN. Univ. Calif. *Phil. Mag.* 28, 583-600(1914).—Gaseous systems are considered containing particles of different masses, and a law is derived for the distribution of momenta, from which it follows that the av. value of the momentum of a particle is the same for particles of all different masses. This equi-partition of momentum is true also for systems of particles which are sepd. by a partition which allows transfer of energy, and hence the equality of the av. values of this quantity becomes the relativity condition for thermal equil. The momentum is proportional to the abs. temp. measured on the thermodynamic scale, and reduced to the quantity $m_0 v^2$ (of Newtonian mechanics) when the velocities are small compared with that of light. In relativity mechanics there can be no possibility of an exact equi-partition of energy. A partial consideration is presented of the actual partition of energy attained at equilibrium. A. T. CAMERON.

Chemical reactions at low pressures. IRVING LANGMUIR. *J. Am. Chem. Soc.* 37, 1139-67(1915).—A new theory of heterogeneous reaction has been given in which the velocity of a reaction between a solid and a gas was considered to be limited, not by the rate of diffusion of the gas mols. through an adsorbed film, but by the rate at which the surface of the metal becomes exposed by the evapn. of the single mols. from an adsorbed layer one mol. deep. If m represents the number of g. of gas mols. which strike a unit surface per sec., its value is $m = \sqrt{M/2\pi RT} p$, where p is the pressure and M the mol. wt. of the gas. At atm. pressure and room temp., this corresponds to 12 liters of air per sq. cm. per sec. The clean-up of O in a W lamp and many other applications of this theory of mol. layers have been discussed. Cf *C. A.* 7, 723, 1322-3, 1677; 8, 1043, 1230; 9, 263, 985. E. B. MILLARD.

Gas equilibria and a test of the formula of van der Waals, Jr. F. E. C. SCHEFFER. Univ. Amsterdam. *Verslag. Akad. Wetenschappen* 23, 688-96, 950-65(1914).—In order to calc. the const. of gaseous equilibria it is necessary first to derive an expression for the entropy of the reacting gases. Such expressions have already been given by Keesom, by Tetrode and by Sackur, and quite recently van der Waals, Jr., has calc. equil. const. of gas reactions from an expression involving the algebraic sum of the separate entropies. The present communication shows how the above mentioned expressions may be applied to data given in the literature. The reactions considered are $I_2 \rightleftharpoons 2I$, $2HCl \rightleftharpoons H_2 + Cl_2$, $2HBr \rightleftharpoons H_2 + Br_2$ and $2HI \rightleftharpoons H_2 + I_2$. From the calcns. of the dissociation equilibria of I and of the 3 halogen acids the moments of inertia of the various mols., and hence the mean molar radii may be calc. The values so found agree with the detns. of molar radii by other means (from viscosity, from re-

fractive index and from the const. b in the equation of state). This result, already reached by Sackur, but only in a comparatively rough way, confirms the expression of van der Waals, Jr., in which the vibrations of the atoms are taken into account.

L. H. ADAMS.

The laws of Tate. A reply to Lohnstein. J. L. R. MORGAN. Columbia Univ. *Z. physik. Chem.* 89, 385-410(1915).—The exact limits have been detd. between which the laws, surface tension = const. $\times$ wt. of drop, and wt. of drop/diam. of mouth piece = const., hold, and, moreover, it has been shown that the validity of these laws can be predicted with certainty from previous observations on the form of drops. When the drop is "normal," both the foregoing laws are valid, and have actually been found to hold in the case of 131 pure liquids and 59 aq. solns. The values of the surface tension of 69 liquids detd. by this method agree within a few tenths of 1% with the values obtained by the method of capillary rise. It has been shown that the new definition of normal mol. wt. in the liquid condition (which states that a liquid is normal when, on substituting its gaseous mol. wt., along with the data for γ and density (d) at t_0 , in the equation $M/d = 2.115(t_c - t_0 - 6)$, a value is obtained for t_c that is independent of the temp. of observation) holds for the 56 liquids which are generally considered as non-associated. The validity is so satisfactory that the values obtained for t_c at different temps. only differ by a few tenths of 1% for each liquid. Further, it has been shown that, in general, neither the law of Tate nor that given by Lohnstein holds.

Notes on the Noble gases. W. S. ANDREWS. *Gen. Elec. Rev.* 18, 408.—A review. C. G. F.

The molecular structure of solid isotropic and anisotropic binary mixtures. G. TAMMANN. *Z. anorg. Chem.* 90, 297-327(1914); see C. A. 9, 875. G. W. M.

Influence of salts on the equilibrium in the system water-acetone. W. JACOBS. *Rolduc. Chem. Weekblad* 12, 312-20(1915).—A summary of results obtained with 8 ternary and 3 quaternary systems of the type H_2O-Me_2CO -salt-(salt), in which 2 liquid layers are formed. In general, the temp. and compn. of the critical soln., together with a few isotherms, consisting of the solubility line of the solid phase and the binodal curve, are given, but no experimental details or detailed results. In the system $H_2O-Me_2CO-NaCl$, the ternary critical temp., T_k , is -3.8° ; the critical soln. L_k contains 54% Me_2CO , 6% $NaCl$, 40% H_2O ; at 25° mixts. of H_2O and Me_2CO containing less than 25% or more than 84% Me_2CO can be satd. with $NaCl$ without unmixing. In the system $H_2O-Me_2CO-NH_4Cl$, T_k is 18.5° and L_k contains $\approx 57\%$ Me_2CO , $\approx 6\%$ NH_4Cl , $\approx 37\%$ H_2O ; isotherms at 18° and 25° were detd.; at 25° addition of NH_4Cl causes unmixing in mixts. of H_2O-Me_2CO containing from 42 to 82.5% Me_2CO . The systems $H_2O-Me_2CO-NaNO_3$ and $H_2O-Me_2CO-KNO_3$ are similar; the values of T_k are, resp., 41.3° and 61.2° . In the system $H_2O-Me_2CO-(NH_4)_2SO_4$, T_k lies below -20° and was not realized; at 30° addition of $(NH_4)_2SO_4$ causes unmixing in mixts. containing between 1.3 and 76.5% Me_2CO . In the system $H_2O-Me_2CO-Li_2SO_4$, T_k lies below -20° and was not realized; at 28° the isotherm consists of the solubility line of Li_2SO_4 , which practically is a point close to the Me_2CO apex of the component triangle, the solubility line of $Li_2SO_4 \cdot H_2O$, and the binodal curve; at 28° addition of $Li_2SO_4 \cdot H_2O$ causes unmixing in mixts. containing between 9.5 and 57% Me_2CO . In the system $H_2O-Me_2CO-Na_2SO_4$, both Na_2SO_4 and $Na_2SO_4 \cdot 10H_2O$ can exist in equil. with 2 liquid layers; the transition temp. lies at 32° ; T_k is 29.6° and L_k contains $\approx 12\%$ Me_2CO , $\approx 13\%$ Na_2SO_4 , $\approx 75\%$ H_2O ; at 35° , addition of Na_2SO_4 causes unmixing in solns. containing between 2.5 and 45.5% Me_2CO ; at 31° , between 2 and 40% Me_2CO . In the system $H_2O-Me_2CO-CaCl_2$, T_k lies below -20° ; the 28° isotherm consists of the solubility lines of $CaCl_2 \cdot 6H_2O$, α - $CaCl_2 \cdot 4H_2O$, and $CaCl_2 \cdot 3Me_2CO$, and the binodal

curve, which seps. the last-named solubility curve into 2 parts. The graphic representation of the quaternary system $\text{H}_2\text{O}-\text{Me}_2\text{CO}-\text{NaCl}-\text{CuCl}_2$ at 30° consists of the solubility surfaces of NaCl , $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ and $\text{CuCl}_2 \cdot 2\text{Me}_2\text{CO}$ and the binodal surface, which intersects the NaCl solubility surface only. On addition of CuCl_2 to the ternary complex $\text{NaCl}-\text{L}_x-\text{L}_y$ the 2 layers approach each other in compn. and become identical; the compn. of the critical soln. is 41% Me_2CO , 12% CuCl_2 , 8% NaCl , 39% H_2O ; addition of CuCl_2 to the ternary system also raises T_k . Addition of BaCl_2 to the ternary system $\text{H}_2\text{O}-\text{Me}_2\text{CO}-\text{NH}_4\text{Cl}$ lowers T_k ; at 18° the graphic representation of the system consists of the solubility surfaces of NH_4Cl , $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$, BaCl_2 , and the binodal curve; the latter lies wholly within the tetrahedron, and intersects the surfaces of both NH_4Cl and $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$; the relations at 30° are similar; T_k is 14.6° , L_k contains 58% Me_2CO , 6% NH_4Cl , 0.5% BaCl_2 , 35.5% H_2O . In the 2 quaternary systems shown, unmixing takes place only in one of the ternary systems; both of the ternary systems, that with Li_2SO_4 and that with $(\text{NH}_4)_2\text{SO}_4$, form 2 liquid layers; addition of either Li_2SO_4 to the $\text{H}_2\text{O}-\text{Me}_2\text{CO}-(\text{NH}_4)_2\text{SO}_4$ system, or *vice versa*, results in a lowering of T_k . The graphic representation of this system consists of the surfaces of Li_2SO_4 , $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$, LiNH_4SO_4 , and $(\text{NH}_4)_2\text{SO}_4$ and the binodal surface; $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$, LiNH_4SO_4 , and $(\text{NH}_4)_2\text{SO}_4$ can each exist in equil. with 2 liquid layers.

GEORGE W. MOREY.

Critical end-points and the system ethane-naphthalene. ADA PRINS. Amsterdam. *Proc. Acad. Sci. Amsterdam* 17, 1095-1111(1915).—Several systems were studied in an attempt to find one of the type ether-anthraquinone. In the system ether-alizarin, the 1st critical end-point (p) lies at 196.4° and 37.5 atm., but the 2nd critical end-point (q) could not be detd. exactly because of the very dark reddish color of the fluid and liquid phases; q lies at about 258° . In the system ether-isophthalic acid, p is at 196.1° and 36.8 atm.; q could not be detd. because of decompn. The systems ether-hexachlorobenzene and hexane-anthraquinone do not show critical end-points. The systems CO_2 -naphthalene and CO_2 -diphenyl both show a p at realizable temps. and pressures, but the 3-phase line at higher temps. in both cases rose so steeply that further study was abandoned. The system ethane-naphthalene belongs to the type in which the 2 components are not completely miscible at high temp.; p is at 39.40° and 52.89 atm. (compn. not given); for C_2H_6 , t_k is 32.32° , p_k , 48.13 atm. The point q could not be observed directly because of the small temp. change caused by a considerable pressure change, and because of the tendency to persist in metastable conditions, both because of failure of the solid phase to separate and to dissolve. By means of P - T detns. and study of the end condensations of mixts. near the critical mixt. in compn., q was found to be at 57.4° , 124.8 atm., 20-25 mol. % C_2H_6 . GEORGE W. MOREY.

Equilibrium in the system $\text{Pb}-\text{S}-\text{O}$; the roasting process. W. REINDERS. Delft. *Verslag. Akad. Wetenschappen* 23, 596-610(1914).—Preliminary consideration of the numerous possible reactions involved in the Pb roasting process indicated that the phases present are Pb , PbS , PbSO_4 , PbO and SO_2 , if the small amt. of PbS in the vapor and the slight solubility of PbS in Pb be neglected. It is convenient to refer all reactions to the 3-component system $\text{Pb}-\text{S}-\text{O}$, and tentative diagrams of this system are exhibited. It was thought at first that of the 2 pairs of phases, $\text{Pb} + \text{PbSO}_4$ and $\text{PbS} + \text{PbO}$, one must be stable and the other meta-stable, but eventually it was found that the stable-phase pair is $\text{Pb} + \text{PbO} \cdot \text{PbSO}_4$. Vapor pressure (of SO_2) measurements of numerous mixts. were made in an electrically heated porcelain tube, temps. being measured with a Pt-PtRh thermocouple. The monovariant systems were found to be (1) $\text{PbS}-\text{PbSO}_4-\text{PbO} \cdot \text{PbSO}_4$, (2) $\text{PbS}-\text{PbS}-\text{PbO} \cdot \text{PbSO}_4$, (3) $\text{PbS}-\text{PbO} \cdot \text{PbSO}_4-(\text{PbO})_2-\text{PbSO}_4$, (4) $\text{PbS}-(\text{PbO})_2 \cdot \text{PbSO}_4-(\text{PbO})_2 \cdot \text{PbSO}_4$, (5) $\text{PbS}-(\text{PbO})_2-\text{PbO}$. The subscripts attached to Pb refer to definite amts. of PbS in solid soln. with Pb . From the vapor

pressure measurements the heat of reaction of $\text{PbS} + \text{PbSO}_4 = 2\text{Pb} + 2\text{SO}_2$ was calcd. by means of the ordinary equation $\log p = -Q/(4.571T) + C$, and found to be -99543 cal., which is in good agreement with the value 92470, calc. from the known heats of formation of the compds. involved.

L. H. ADAMS.

A. Smits' "new" "theory" of allotropy. H. R. KRUYT. Utrecht. *Z. physik. Chem.* 89, 464-6(1915); cf. *C. A.* 5, 1861.—Polemical. H. JERMAIN CREIGHTON.

Metastability of metals as consequence of allotropy and its significance for chemistry, physics, and technical work. ERNST COHEN. Utrecht. *Z. physik. Chem.* 89, 489-92(1915); cf. *C. A.* 8, 2295. H. JERMAIN CREIGHTON.

Physico-chemical studies of cadmium. II. ERNST COHEN AND W. D. HELDERMAN. Utrecht. *Z. physik. Chem.* 89, 493-510(1915); cf. *C. A.* 8, 2295.—It has been shown by dilatometric and electromotive methods that Cd is a metastable structure, there being simultaneously present more than 2 allotropic modifications of the metal. The electromotive behavior of different forms of Cd has been more closely examd. A number of phenomena, hitherto not understood, have been explained by means of newly obtained results.

H. JERMAIN CREIGHTON.

New researches on metallic clouds. I. Lead clouds in lead chloride. RICHARD LORENTZ AND W. EITTEL. Frankfurt a/M. *Z. anorg. Chem.* 91, 46-56(1915); cf. *C. A.* 5, 2456.—Optically clear PbCl_2 crystals were prepd. by passing a current of $\text{Cl} + \text{HCl}$ through molten PbCl_2 ; good crystals were obtained by cooling rather rapidly and using a flat-bottomed tube; cryst. and optical details are given. Metallic clouds were obtained by heating the above optically clear PbCl_2 to $100-150^\circ$ above its m. p., and adding a small piece of clean Pb; the product so obtained is grayish but still transparent. Ultramicroscopic observations showed the presence of innumerable particles similar to those found in ruby glass or similar dispersed systems; photomicrographs are given illustrating the striking optical effects obtained because of the strong birefracton of the melt. The cloud, as previously stated by L., consists of fine metallic particles; in a molten salt decompn. probably takes place such, e. g., as $n\text{MCl}_2 = [(n-1)\text{MCl}_2 + \text{M}] + \text{Cl}_2$; such a decompn. explains the fact that commercial salts do not give an optically clear fusion, and that purified salts if kept molten too long become clouded. II. Silver clouds in silver chloride and silver bromide. *Ibid* 57-60.—Optically clear AgCl was prepd. by passing dry Cl containing a small amt. of dry HCl through the molten material and cooling in the dark; AgBr by dropping a slow stream of Br on to the surface of the molten mass and cooling in the dark. Clouded preps. were obtained by heating to 1000° , adding Ag, heating 5 min. to 1100° , cooling to $500-600^\circ$ in the furnace, and cooling in the dark; clouded preps. could be cleared by repeating the treatment with Cl or Br. In the ultramicroscope the clouded preps. showed the presence of an extraordinarily large number of colloidal particles, the analogy with An ruby glass being closer than was the case with the PbCl_2 clouds. Optically clear crystals in the ultramicroscope remained clear, i. e., no Tyndall cones could be observed, but on long illumination the crystals became more and more opaque, the color changing through violet to black with AgCl , to black without a violet stage with AgBr . III. Thallium clouds in thallous chloride and thallous bromide. *Ibid* 61-5.—Optically clear TlCl and TlBr could not be prepd.; the method previously used led to oxidation with double salt formation. Tl clouds were produced in TlCl melts by electrolysis, in TlBr melts by addition of Tl; the clouded melts showed the presence of highly dispersed Tl particles, often with a definite orientation. The decompn. in the case of Tl halides probably takes place with formation of thallic halides, which tend to form double salts with the thallous halide.

GEORGE W. MOREY.

The allotropy of potassium. I. ERNST COHEN AND S. WOLFF. Utrecht. *Proc. Acad. Sci. Amsterdam* 17, 1115-8(1915) (English).—From an exam. of the data of

Hagen (*Wied. Ann.* 19, 436(1883)) on the coeff. of expansion of K, carried out with a dilatometer, it is concluded that K can undergo transformation into a 2nd allotropic modification, and that the metal as it has hitherto been known at ordinary temp. is a metastable system in consequence of the presence of both forms together.

GEORGE W. MORBY.

Compounds of arsenious oxide. I. F. A. H. SCHREINEMAKERS AND W. C. DE BAAT. Leiden. *Proc. Acad. Sci. Amsterdam* 17, 1111-5(1915).—A detn. of the solubility isotherm at 30° in the system $\text{H}_2\text{O}-\text{As}_2\text{O}_3-\text{NH}_3$. The solid phases are As_2O_3 , whose satd. aq. soln. contains 2.26% As_2O_3 ; NH_4AsO_3 , sol. in H_2O without decompn.; its satd. soln. contains 19.2% NH_4AsO_3 ; and (probably) $\text{NH}_4\text{H}_2\text{AsO}_3$, although the region for this latter compd. could not be detd. with certainty. GEORGE W. MORBY.

The relative dimensions of molecules. A. O. RANKINE. Univ. Coll., London. *Phil. Mag.* 29, 552-5(1915).—From measurements of the viscosities, and the variations of the viscosities with temp. of the gases Cl, Br, I, A, Kr, Xe, it is shown, using Sutherland's modification of Maxwell's formula correlating the viscosity of a gas with the dimensions of the mols. (*Phil. Mag.* 36, 507 (1893)), that the dimensions of each corresponding gas in the 2 groups are in const. proportion, the radius of the mol. of a halogen gas being 1.24 times as great as that of the corresponding inert gas (on the assumption that all the mols. are spherical), whence it follows that the halogen mols. have practically twice the vol. of the corresponding inert mols., and the densities of corresponding mols. in the 2 series should be approx. equal. It is further shown that the work done in sepg. to a great distance 2 mols. of a halogen gas originally in contact is 2.3 times as great as for 2 mols. of the corresponding inert gas.

A. T. CAMERON.

The velocity of adsorption retrogression. H. FREUNDLICH AND E. HASE. Brunswick. *Z. physik. Chem.* 89, 417-63(1915).—The velocity of adsorption retrogression has been measured with HgS sol, using new fuchsin and auramine as coagulators, and with S sol, using new fuchsin alone. In all cases the process appeared to be autocatalytic. In agreement with previous expts., the process, in the case of HgS sol, may be described by the differential equation $dx/dt = 2k_1t(1 + b_1x)(1 - x)$, or by $dx/dt = 2k_2t(1 + b_2x)(1 - x)$, and in the case of S sol by the equation $dx/dt = k_1(1 + b_1x)(1 - x)$. In these equations, x represents the increase in the concn. of the dye, and k and b are consts. HgS sol and S sol differ markedly in their behavior: HgS sol remains undistributed as flakes throughout the liquid during the whole process, while S, on the other hand, collects together in little toothed balls which, towards the end of the process, crumble into partially cryst., badly wetted flakes. The dependence of the velocity of the adsorption retrogression on the concn. of the dye is strikingly great. Under certain conditions, the const. k increases about 100% for a 10% increase in the concn. This dependence may be expressed by the equation $k = \chi a^p$, where a is the quantity of dye adsorbed from the adsorbent, and χ and p are consts., the value of the latter lying between 2 and 7. The turning point of the velocity curves depends but slightly, or not at all, upon the concn. of the dye. Small concns. of protective colloids, like saponin, have been found to retard noticeably the adsorption retrogression. As is the case with HgS sol, the dependence of the velocity of adsorption retrogression on temp. is also very great in the case of S sol; A in the Arrhenius equation is about 15000, corresponding to a five-fold increase in the const. per 10°. Comparison of the velocity of coagulation and of adsorption retrogression show that they agree in many points. The results of the investigation have been used to explain a number of adsorption phenomena. In conclusion, it is pointed out that the results obtained support the surface concn. theory of adsorption, and contradict the solid soln. theory.

H. JERMAIN CREIGHTON.

Theory of emulsification. VI. W. D. BANCROFT. *J. Phys. Chem.* 19, 275-309 (1915); cf. *C. A.* 7, 2143, 2881.—Many organic liquids adsorb OH ions from an aq. alkaline soln. Tomlinson's statement that oils cause supersatd. solns. of Na_2SO_4 to crystallize was questioned. Solid particles tend to go into the water phase when shaken with H_2O and a non-miscible organic phase if they adsorb H_2O to the practical exclusion of the other liquid; into the organic phase if they adsorb it to the exclusion of H_2O and into the dineric interface in case they adsorb the 2 liquids simultaneously. The latter case probably produces a homogeneous liquid phase at the surface of the adsorbing particle. A substance in the interface was named "interfacial." Such a substance can be shaken more or less completely out of its suspension in one liquid by adding a second liquid for which the suspended substance is interfacial. Winkelblech's method for shaking out colloids is a method of testing for interfacial substances. It is effective in case a fairly stable emulsion is formed or if the interfacial substance is left, when the drops coalesce, in a form not readily peptized by either liquid.

E. B. MILLARD.

Adsorption. XI. Hysteresis of the degree of hydration of cellulose. A. V. RAKOVSKII. *J. Russ. Phys. Chem. Soc.* 47, 18-21 (1915); cf. *C. A.* 8, 2512.—An exam. of cotton, paper, flax and hemp with respect to the amt. of H_2O they are capable of retaining *in vacuo* showed that the max. of hysteresis for cellulose (1.8% H_2O) is slightly lower than for the starches as found in former investigations. Several tables and curves illustrate the results.

H. M. GORDIN.

The adsorption of dyes by colloidal clay, etc. P. ROHLAND. Stuttgart. *Kolloid-Z.* 16, 16-8 (1915).—A résumé of former articles in which R. calls attention to the fact that the adsorption of dyes by colloidal clay does not depend on the acid, basic or substantive nature of the dye, but as a rule occurs with dyes such as aniline blue, aniline red, malachite green, brilliant green, aurin and alizarin, which have little or no N, while naphthol yellow, vesuvine and safranin which contain considerable N, are very little adsorbed. The fluorescein group is an exception to this rule. H. I. MATTILL.

New method of preparation and some interesting transformations of colloidal manganese dioxide. E. J. WITZEMANN. Chicago. *J. Am. Chem. Soc.* 37, 1079-91 (1915); cf. *C. A.* 6, 3089; 8, 3295.—Colloidal MnO_2 may be obtained by the use of organic reducing agents. It is especially easily obtained by incompletely oxidizing glucose (fructose, galactose) in the cold in alk. soln. with KMnO_4 . The colloidal soln. thus obtained rapidly increases in viscosity until it gels and the rate of change and the max. viscosity are roughly inversely proportional to the amt. of alkali used. This viscous or gel stage subsequently changes into a limpid soln. The properties of the 1st stage agree well with those of a typical emulsoid, while the later stage seems more characteristically a suspensoid. The transformations of the emulsoid are typical and would be normal in every way if it were not for a slower but simultaneous transformation of the emulsoid into the suspensoid, owing to the effect of the alkali in accordance with the generalizations of Mayer *et al.* (*C. A.* 2, 618, 1626). Both transformations are markedly affected by variations in temp., concn. of reacting substances and the amt. of KOH or NaOH used. The limpid form, which is stable for months, was dark brown in color, transparent in thin layers and could be dild. with H_2O to any extent without at once pptg. MnO_2 . The expts. of Bredig and Marck (*C. A.* 5, 2470) and Deiss (*C. A.* 4, 1583) were duplicated with this colloid. E. B. MILLARD.

The effect of added substances in the preparation of colloidal gold solutions by the formaldehyde method of Zsigmondy. KARL HEIGE. Göttingen. *Z. anorg. Chem.* 91, 145-85 (1915).—A study of the effect of added substances on the spontaneous crystg. power (measured by the number of crystal nuclei formed) and the crystn. velocity of colloidal Au formed by reduction of HAuCl_4 solns. by HCHO . (Pure H_2O

which would give clear, reproducible colloidal Au solns. could not be prepd. by distn., the best which could be made containing some organic matter; these impurities, however, were eliminated by letting the water stand some time in glass bottles. On addition of gelatin, Na palmitate, Na stearate, Na oleate, or Na protalbinato to the Au soln. before reduction, the number of particles decreased to a minimum, then again increased with increasing amts. of added substance, and large amts. increased the time required for complete reduction. Gum arabic and starch gave highly dispersed solns., due probably to their reducing action; the effect with the 1st group is probably to be explained by the formation of "colloidal compds." Thoroughly aged, dialyzed SiO_2 solns. also gave a minimum in the number of particles; with fresh solns. the number of particles increased, probably due to organic matter from the parchment; SnO_2 soln. gave results similar to the aged SiO_2 soln.; addition of colloidal Fe_2O_3 resulted in a higher degree of dispersion, but it also caused pptn. because of its positive charge. Of the electrolytes used, NH_4OH , NH_4Cl , $\text{K}_3\text{Fe}(\text{CN})_6$ and $\text{K}_4\text{Fe}(\text{CN})_6$ hindered the formation of nuclei; HCNS , congo red, benzo-purpurin, $\text{K}_2\text{C}_2\text{O}_4$ and Na citrate caused an increase in the spontaneous crystg. power (often due to reduction), as did $\text{C}_6\text{H}_5\text{CO}_2\text{K}$, HCO_2K , KOAc , morphine-HCl, etc.; NaNO_3 , Na_2SO_4 , and rosaniline-HCl tended to coagulate the Au soln.; KCl , KBr and KI gave first a strong increase in the crystn. velocity, after which they caused coagulation; $\text{Sr}(\text{NO}_3)_2$, $\text{Ba}(\text{NO}_3)_2$, and HgCl_2 gave similar results, though the 1st effect was not so marked; $\text{Fe}(\text{NO}_3)_3$ and $\text{Al}(\text{NO}_3)_3$ first had a favorable effect on the formation of nuclei, followed by pptn. by the positively charged oxide formed; CuSO_4 , NiSO_4 , CoSO_4 and $\text{Cr}(\text{NO}_3)_3$ showed only the latter effect. Because of the action of $\text{K}_3\text{Fe}(\text{CN})_6$ in inhibiting the formation of nuclei, when soln. containing nuclei was added the added nuclei alone grew, resulting in particles visible with the ultramicroscope, the number of which could be counted; knowing the amt. of Au dispersed in the added soln. the dimensions of the nuclei could be calcd., assuming the d. of the Au to be 20; the diam. of the nuclei was found to be 3.15μ .

GEORGE W. MOREY.

Experiments with colloidal gold and silver. E. S. BASTIN. *J. Wash. Acad.* 5, 64-71(1915).—*With gold:* A dull brown or black condition of Au is favorable to colloidal Au formation while a lustrous yellow is not. Colloidal Au appeared to originate on the surface of the metal or the sulphide at room temp., and then slowly to undergo diffusion. B. thinks that, while the brown color of some natural Au may be due to impurities, it may also be that it is in a condition approaching the colloidal state. It is probable that in the oxidized zone of ore deposits the presence of colloidal Si takes the Au into colloidal soln. Expts. were carried out first with the aid of gelatin and then with SiO_2 . *With Ag:* In case of Ag, SiO_2 seems to act as an emulsoid. B.'s expts. are justified by the fact that rocks rich in olivine which yields colloidal Si on weathering, gives good evidence of colloidal downward transport of Au and Ag, though the transport of Au or Ag in colloidal soln. is of little importance in formation of ore deposits as compared to salts in true (electrolytic) soln. P. A.

Viscosities of binary mixtures of the associated liquids, water, formic acid and acetic acid. P. B. DAVIS AND H. C. JONES. Johns Hopkins Univ. *J. Am. Chem. Soc.* 37, 1194-8(1915); *C. A.* 7, 928; 8, 449.—Viscosities of these binary mixts. have been detd. at 15° and 25° . The curve for viscosity of HOAc in H_2O showed high maxima of viscosity for both temps. in the neighborhood of 80% HOAc; the other mixts. had only slightly curved plots. E. B. MILLARD.

Similarity of motion in relation to the surface friction of fluids. T. E. STANTON AND J. R. PANNELL. *Trans. Roy. Soc. London (A)* 214, 199-224(1914).—Expts. on the flow of H_2O in pipes of 0.36 to 2.85 cm. in diam., and 28 to 61 cm. long, at stream velocities as high as 5600 cm. per sec., and upon air in these pipes at 190 to 4000 cm.

per sec. have been made. The temp. was not const. throughout the series, but appears to have been taken at whatever temp. the fluid happened to be at the time. The ratio of mean velocity in the pipe to the velocity at the axis has been shown in curves. Using a law of resistance $R = kv^n$, where n was taken as 1.72, the observed resistance was compared with the calcd. The latter was 5% low at a velocity of 1000 cm. per sec. (for the 1.25 cm. pipe), 8.5% low at 2000 cm. per sec., and 15% at 3000 cm. per sec.

E. B. MILLARD.

The preparation of anhydrous solids. W. R. G. ATKINS. Trinity Coll., Dublin. *Nature* 95, 118(1915).—A method is suggested for the prepn. of solid compds. in the anhydrous state, or for obtaining anhydrous tissues for moisture detns. According to this method, the material to be dehydrated is placed in a suitable distg. flask with alc. and C_6H_6 in the proper proportions. When all the turbid ternary mixt. of const. b. p. has been removed by distn. from a water bath, the remaining mixt. of alc. and C_6H_6 may be rapidly distd. away, and the last traces can be removed in a vacuum desiccator. By adjusting the quantities, either alc. or C_6H_6 can be obtained as the residual liquid, and the complete removal of either of them is far more readily effected than is that of water owing to their lower boiling points and greater volatility. The method avoids all risks of oxidation in the case of the drying of plant tissues.

W. H. ROSS.

Fortuitous density changes and opalescence at the critical point of an element. L. S. ORNSTEIN AND F. ZERNIKE. Groningen. *Verslag Akad. Wetenschappen* 23, 52-95(1914).—This article consists of a mathematical treatment in considerable detail of the cause and calcn. of critical opalescence.

L. H. A.

Internal friction of salt solutions. W. HERZ. Breslau. *Z. anorg. Chem.* 89, 393-6(1914); cf. C. A. 8, 1889.—Viscosity detns. were made at 25° with solns. of the chlorides of K, Na, NH_4 , Ba, Sr, Mg, Mn and Cu, sulfates of Mg, Mn, Zn and Cu, and nitrates of Mg, Mn and Pb of various conc. Details of app. and method are not given.

GEORGE W. MOREY.

On a new form of sulfuric acid drying vessel. THE EARL OF BERKELEY AND E. G. J. HARTLEY. *Phil Mag.* 29, 609-13(1915).—New forms of P_2O_5 and H_2SO_4 drying tubes are described. Comparative expts. show that H_2SO_4 is capable of drying air as completely as P_2O_5 , at least to the extent required in measuring the vapor pressure of aq. solns. In the new form of app. it is not necessary to bubble the air through the acid, but only to lead it over the surface; thus the risks of introducing acid spray into the air stream and of uncertain changes in the vol. of the air current are avoided. The vapor pressure of H_2SO_4 itself is shown to be too small to be of importance in such work. Pure, anhydrous $CuSO_4$ is a very efficient drying agent for air, containing only traces of moisture (it will take up 0.05% of its own wt.) and has the advantage that it can be used over again after heating to 210-220° in an air stream. Its dehydrating property seems difficult to explain, since according to theory it should not absorb H_2O vapor unless the partial pressure is greater than that of the hydrate $CuSO_4 \cdot H_2O$.

A. T. CAMERON.

The hydrate problem. I. Calculation of the quantity of water involved by ions from electrolytic mobilities. HEINRICH REMY. Freiburg. *Z. physik. Chem.* 89, 467-88(1915).—It is pointed out that, if the H ion is considered as unhydrated, the water enveloping the ions in infinitely dil. solns. may be ascertained by comparison of the mobilities, with the help of Stokes' formula. It has been found that in a great number of cases the radius of the water-enveloped ion differs from the radius of the unhydrated ion by exactly the diam. of a water mol. In view of this the supposition is made that these ions are just covered with a layer of H_2O mols. The following values have been calcd. for the number of H_2O mols. which envelope certain mono-

valent ions: H⁺ 0, Cs⁺ 13, Rb⁺ 14, K⁺ 16, NH₄⁺ 17, Na⁺ 66, Li⁺ 120, Tl⁺ 16, Ag⁺ 29, OH⁻ 1, I⁻ 15, Br⁻ 15, Cl⁻ 16, ClO₄⁻ 17, ClO₃⁻ 26, NO₃⁻ 19, CNS⁻ 25. In conclusion it is pointed out that this H₂O envelope is made up of hydrate and adhesion H₂O which is in good agreement with Werner's supposition.

H. JERMAIN CREIGHTON.

Influence of temperature and solvent on the molecular weight of dissolved substances. ERNST BECKMANN AND MARIA MAXIM. Berlin-Dahlem. *Z. physik. Chem.* 89, 411-6(1915).—It has been found that the degree of association of phenol in CCl₄ is not very sensitive towards moderate lowering of the b. p. (75.4°-54.1°). During the transition from the b. p. of CCl₄ to its f. p., the degree of association is more than doubled. In freezing CHBr₃ (m. p. 8°) an intermediate association value has been obtained. In spite of the low temp., both with CCl₄ and CHBr₃, diln. causes the association to disappear completely. The influence of diln. with a solvent has been found more effective in this connection than a temp. increase of about 100°, even though the solvent were relatively indifferent.

H. JERMAIN CREIGHTON.

Freezing point-solubility law for ideal solutions. E. W. WASHBURN AND J. W. READ. Univ. Illinois. *Proc. Nat. Acad.* 1, 191-5(1915).—For "ideal" solns. (those in which the constituents are completely miscible and in which mixing takes place without heat effect or change in vol.) the equations $dT/dx_A = RT^2/L_A x_A$ and $dT/dx_A = RT^2/L_B x_B$ can be shown thermodynamically to express the change of f. p. caused by an increase in the mole-fraction of each component. The soln. is composed of the substances *A* and *B*, *T* is the abs. temp., *L* the latent heat of fusion per mole and *x* the mole-fraction, in soln., of the substance indicated by the subscript. By means of the integrals of these equations (assuming *L* to be independent of the temp. for the range covered) the eutectic has been calc. for C₆H₆-C₁₀H₈, C₆H₆-C₆H₅C₆H₅ and C₁₀H₈-C₆H₅C₆H₅. The eutectic temps. calc. were, resp., -3.48°, -5.8° and 39.4°; those obtained by careful expts. were -3.56°, -6.1° and 39.4°. This shows that the solns. are very close to ideal solns. When a substance *A* is dissolved in any solvent *B* with which it forms an ideal soln., its solubility (expressed in terms of its mole-fraction in the satd. soln.) is entirely independent of the nature of the solvent *B*, and is therefore the same for all solvents. By an application of this principle, the question as to whether racemates exist as such in the liquid state and to what extent they exist could be solved, since optical isomers are examples of substances which form ideal solns. with each other.

E. B. MILLARD.

Transformation of the trichlorides of chromium and titanium in aqueous solution. ADOLF HEYDWEILLER. Rostock. *Z. anorg. Chem.* 91, 66-74(1915).—CrCl₃·6H₂O exists

in three forms, green $\left[\begin{array}{c} \text{CrCl}_3\text{H}_2\text{O} \\ \text{CrCl}_3\text{H}_2\text{O} \\ (\text{H}_2\text{O})_4 \end{array} \right]^-$, green $\left[\begin{array}{c} \text{CrCl}_3\text{H}_2\text{O} \\ \text{Cr} \\ (\text{H}_2\text{O})_5 \end{array} \right]^{--}$ and violet $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$;

H. studied the rate of transformation in solns. by detg. the change with time of the cond. and density of solns. of various strengths at 18°. The first green form was used in making the solns. In a soln. containing 0.853 mol. per l., the sp. cond. increased from $10^3 K_0 = 71.6$ to $10^3 K_\infty = 99.8$ in 153 days, and the d. (expressed as δd_{18} of the soln. —1) increased from $10^3 \delta_0 = 10.972$ to $10^3 \delta_\infty = 11.440$; the values for *m* = 0.640 mol. per l. were, resp., 60.60, 87.50, 8.318 and 8.690 (time, 61 days); for *m* = 0.427 mol. per l., 42.87, 67.70, 5.333, 5.843 (time, 61 days). The above results can be expressed by the formulas: $\ln[(K_\infty - K_0)/(K_\infty - K_t)] = at$ and $(\sigma_\infty - \sigma_0)/(\sigma_\infty - \sigma_t) = bt$, in which the values of *a* and *b* for the above 3 dilns. are, resp., 0.0495, 0.0462, 0.0702, 0.0675; 0.1246, 0.1255. That the reaction is not monomol., as implied by the form of the above expressions, is shown by the trend of the consts. with diln. From the fact that the products $am(1-i)$ and $bm(1-i)$ are const. it is concluded that the reaction is between the non-ionized mol. and H₂O;

the rate of change of the 1st green salt into the 2nd is very great, and K_0 refers to the latter, K_∞ to the violet salt. Similar expts. with BeCl_2 , NiCl_2 , AlCl_3 , and FeCl_3 showed that no change in cond. took place in 9 months. The d. of TiCl_3 solns. remained const., but the specific cond. changed with time; m , $10^3 K_0$, $10^3 K_\infty$, and a found were: 1.228 mols. per l., 118.9, 220.0, 0.006; 0.609 mol., 96.9, 175.5, 0.047; 0.297 mol., 58.2, 105.0, 0.20. The reaction in this case is due to oxidation to oxychloride, and the increase in cond. to the liberated H^+ .

GEORGE W. MORREY.

Hydrous chromic oxide. C. F. NAGEL, JR. *J. Phys. Chem.* 19, 331-7 (1915).—Good jellies can be obtained by adding KOH to a $\text{Cr}_2(\text{SO}_4)_3$ soln.; but the alkali must be added quickly and not in great excess. Hydrous chromic oxide is peptized by caustic alkali. It can adsorb the hydrous oxides of Fe, Mn, Co, Ni, Cu and Mg to some extent without coagulation, and thus carries these oxides into colloidal soln. These hydrous oxides adsorb chromium oxide and therefore take it out of colloidal soln. in alkali. When the oxides are present in sufficient amt., they decolorize a green soln. of Cr_2O_3 peptized by alkali. In presence of glycerol hydrous Fe_2O_3 is peptized by alkali, and consequently does not tend to carry down the chromium oxide. In presence of a Cu salt, hydrous chromium oxide is peptized by NH_3 .

W. H. S.

Ammonium magnesium sulfate (cerbolite). I. Solubility, freezing curve and cryohydric point. I. C. PORLEZZA. *Univ. Pisa. Atti accad. Lincei* 23, II, 596-9 (1914).—This salt occurs as a by-product in the Tuscan boric acid industry. Industrially the NH_3 is removed with lime and the residue taken up with H_2SO_4 . Since in this way the MgO and part of the H_2BO_3 are lost, P., at the suggestion of Nasini, undertook to study the equil. relationships of this salt more closely. The f. p. of solns. of various concs. from 0.072 mol. $(\text{NH}_4)_2\text{Mg}(\text{SO}_4)_2$ to 100 mols. H_2O up to solns. of 0.648 mol. were detd. The curve was traced and the cryohydric point was found to be at the latter conc. at -2.34° . From the solubilities of $(\text{NH}_4)_2\text{Mg}(\text{SO}_4)_2$ as given by Siedell (*Solubility of inorg. and org. substances*, 1907, p. 34) and Lothian (*C. A.* 4, 1719) the solubility curve was constructed and found to intersect the f. p. curve as it should at the cryohydric point. II. P. detd. the solubility of $(\text{NH}_4)_2\text{Mg}(\text{SO}_4)_2$ in H_2O at various temps. in a thermostat with great care; the amt. of this salt dissolved in 100 g. H_2O at 0° is 11.83; at 10° 14.61; 15° 16.27; 20° 17.96; 25° 19.69; 30° 21.71; 40° 25.86; 50° 30.17; 60° 35.17; 70° 40.98; 80° 42.32; 90° 56.32; 100° 65.72, resp. The cryohydric point according to the data of S. is -1.90° , from those of L. -2.45° and from P.'s data -2.40° (detd. experimentally -2.34°). The solubility for the cryohydric temp. as detd. from the curves is 10.75 g. in 100 g. H_2O . The equation for the solubility is $S = 10.55 + 0.2215t + 0.000668t^2$, which is correct to 1%. In all expts. the comp. of the hydrate was taken as $(\text{NH}_4)_2\text{Mg}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ and was never found to vary more than 0.5% from this value.

E. J. WITZEMANN.

Molecular complexity of acetic acid. G. M. BENNETT. *J. Chem. Soc.* 107, 351-60 (1915).—The surface tension of AcOH has been detd. in the absence of air, the capillary rise method, between 15° and 150° in an app. patterned after that of Hewitt and Winnill (*J. Chem. Soc.* 91, 441 (1907)). The values were calc. from the equation $\gamma = \frac{1}{2}(h + r/3)r(d - d')$, where h is the capillary rise, d the density of the liquid, and d' that of the vapor, the latter becoming of importance at higher temps. When observed heights of rise were plotted against temp., a smooth curve was obtained which was practically a straight line. The criterion of non-association should not be the absolute value of $k = d[\gamma(Mv)^{2/3}]/dt$, but rather its constancy for a given liquid, and the value 2.121 found by Ramsay and Shields has no general significance. Values of this function and of the total mol. surface energy, $[\gamma - t(d\gamma/dt)](Mv)^{2/3} = K$, have been calc. for the whole range of temp. K remains sensibly const. over the whole range, k decreases only from 1.275 to 1.250. There are 2 possibilities: (1) the mol.

$(C_2H_4O_2)_n$, (where n may be 1, 2, 3 etc.), is behaving as a simple mol. of considerable stability and the liquid consists exclusively of such mols., (2) there is a state of equil. such as $(C_2H_4O_2)_2 \rightleftharpoons 2C_2H_4O_2$, which is independent of the temp. In the latter case the dissociation of the complex must involve no thermal change, and this is shown to be untrue. The conclusion is that a mol. $(C_2H_4O_2)_2$ exists throughout this temp. range.

E. B. MILLARD.

Solubility of carbon dioxide in water in the presence of starch. ALEX. FINDLAY AND O. R. HOWELL. *J. Chem. Soc.* 107, 282-4(1915); cf. *C. A.* 8, 3734.—The solubility has been redetd. with greater care. Data are given at 25° for the solubility in cc. per cc. of water for pressures from 272 to 960 mm. in pure H_2O ; then the solubility in 5% starch solns. prepd. in 4 different ways. For H_2O the mean value was 0.824. The solubility in the presence of starch was not affected by such variations as arose from differences in method of prepn. of the solns. (time of boiling, rate and method of cooling, etc.). This is in marked contrast to the results of F.'s previous investigations in which the rate of evolution of CO_2 from starch solns. was influenced by these causes. Cf. *C. A.* 8, 3734.

E. B. MILLARD.

Velocity of ionization at low temperatures. A. R. NORMAND. *J. Chem. Soc.* 107, 285-90(1915).—A temp. of -98° was maintained by mixing MeOH with liquid air until a mush of solid was obtained. This equil. temp. was fairly const. EtOH was used as the bath liquid and as solvent for the KI, which served as solute. 100 g. of EtOH dissolve 1.138 g. KI at -98° , the solute being about 50% ionized at this temp. When a portion of this satd. soln. was quickly mixed with an equal amt. of EtOH, the cond. should change gradually if ionization at this temp. were a slow process. No indication was obtained that this was the case, for as soon as the temporary disturbance due to mixing had disappeared, the cond. remained const. Similar results were obtained with 1% KI in an equimol. mixt. of EtOH and MeOH at -117.6° . This mixt. behaved like a glass, having no definite m. p. When it was immersed in liquid air, the vol. decreased and the mixt. became solid at about 150° . If the velocity of ionization doubles for every 10° rise in temp., ionization would take place at room temp. in less than 0.01 sec., probably much less.

E. B. MILLARD.

Influence of sucrose and alkali chlorides on the solvent power of water. J. C. PHILIP AND A. BRAMLEY. S. Kensington. *J. Chem. Soc.* 107, 377-87(1915).—Expts. have been made on the distribution of EtOAc, PhOH and acetone between H_2O or aq. solns. of sucrose and alkali chlorides and petroleum or C_6H_6 at 20° . The lowering of the solvent power shows a distinct increase with diln. in practically every case. Whatever is the cause of the diminished solvent power of H_2O in the presence of the added substance, it is some factor which becomes relatively more important as the proportion of H_2O increases. From calcns. based on the data, the av. mol. hydration of sucrose ranged from 11 for the more dil. solns. to 6.5 for the more conc. ones. If the decrease in solvent power of NaCl solns. is due to the hydration of NaCl alone, the av. mol. hydration would lie between 9.5 for more conc. solns., (4 N) to 17.8 at 0.5 N. For KCl the expts. are not so good, but the corresponding values of hydration are 8.6 at 4 N and 16.4 at 0.5 N, somewhat less than for NaCl. Results for LiCl cannot be used to calc. the hydration, for all of the distributed substances are able to dissolve LiCl in appreciable quantities. The calcns. made showed the same hydration for LiCl as for NaCl, while other sources show that the Li salt is almost surely more hydrated.

E. B. MILLARD.

A peculiar form of caffeine-sodium salicylate. R. E. LIESEGANG. Frankfurt. *Kolloid-Z.* 16, 13-6(1915).—When a thin layer of a soln. of caffeine-sodium salicylate is allowed to dry out it forms a continuous film made up of very narrow alternate ridges and depressions. If water is poured over a very concd. soln. of caffeine-sodium

salicylate and the container slowly heated on the water bath without mixing, as many as 8 distinct layers, of different light refraction and different conc., may be formed. The same phenomenon will occur if water is poured over a concd. soln. of gelatin and the container warmed. This formation may be preserved by suddenly cooling to the point of solidification of the gelatin solns. This offers a new hypothesis for the apparent stratification of deep rocks which have suffered gradual cooling from above.

H. I. MATTILL.

Flame reactions. IV. W. D. BANCROFT AND H. B. WEISER. Cornell Univ. *J. Phys. Chem.* 19, 310-30(1915); cf. *C. A.* 8, 1903, 2103; 9, 167.—Salts of Li, K and Na gave 2 spectra in the Bunsen flame; one of these continuous, the other a line spectrum. The introduction of HCl into the Bunsen flame cuts down the intensity of the line spectra. With a flame of H burning in an atm. of Cl, the line spectra disappeared completely. The *D*-lines were obtained faintly when NaCl was introduced into a flame of Cl burning in H. The blue luminescence of Na without the yellow was obtained when Na salts were introduced into H flames burning in Cl; when Na burned slowly in O, Cl, or Br; when a Na salt was fused, when cathode rays acted on NaCl; when anode rays first acted on it; when the colored residue obtained by the action of anode or cathode rays on NaCl was heated; and when NaCl was pptd. rapidly from aq. soln. by HCl or EtOH. Yellow luminescence, accompanied by the fainter blue, was obtained when canal rays acted on NaCl or when Na was burned rapidly in O, Br or Cl. The blue luminescence of Na was due to reactions from Na ion to undissociated Na salt; the yellow was due to some stage in the reaction from Na vapor to Na ion. The diminished intensity of line spectra in the H-Cl flame or in a flame to which HCl has been added, was due to the forcing back of the dissociation of the salts. They dissociated only slightly into ions and not at all or very slightly into free metal. E. B. M.

The firing of gases by adiabatic compression. III. The ignition-points of mixtures of electrolytic gas with argon. Ratio of the specific heat for nitrogen and hydrogen. J. M. CROFTS. Manchester Univ. *J. Chem. Soc.* 107, 290-305(1915).—Various mixts. of gas were compressed till ignition occurred. The temps. of ignition were detd. by calcg. from the vols. observed and from assumed values of C_p and γ (sp. heat at const. pressure and ratio of sp. heats, resp.) These assumed values were regarded as somewhat doubtful. The results thus obtained show that the temp. of ignition rises regularly, in proportion to the inert gas added to the electrolytic mixt., whether this gas is A or H. This fact, since A is certainly inert, indicates that H is also inert, and C. also considers that both gases when added to the electrolytic mixt., alter the ignition temp. to exactly the same extent. By means of this assumption he compares the results for A (whose sp. heat is known) and H to get C_p and γ for electrolytic gas. Here he assumes that H and electrolytic gas have the same values. By means of the result for electrolytic gas he next finds values for C_p and γ for H and N. The value of C_p for H now comes 2% different from that for electrolytic gas, but C. does not revise his basic detn., where the 2 were assumed to be equal. The *uncorrected* value of C_p for electrolytic gas had agreed to 0.0004 with that given by Lewis and Randall. For H he finds that γ varies from 1.389 to 1.374, and C_p from 5.103 to 5.311 as the temp. interval changes from 15-332° to 15-689°. For N, γ varies from 1.404 to 1.398, and C_p from 4.913 to 4.989 as the interval changes from 15-532° to 15-702°. The variations are linear within the observational errors. These values agree well with those of other observers. The ignition point of electrolytic gas is 520°, raised to 674° by diln. with 4 vols. of A. W. P. WHITE.

The firing of gases by adiabatic compression. IV. The ignition points of mixtures of electrolytic gas with carbon dioxide. Ratio of the specific heats for carbon dioxide. J. M. CROFTS. Manchester Univ. *J. Chem. Soc.* 107, 306-13(1915).—CO₂ was

treated as H and N were in the paper of the preceding abstract. As a result, γ was found to vary from 1.254 to 1.251 and C_p from 7.815 to 7.909 as the temp. interval increased from 15–532° to 15–570°.

W. P. WHITE.

Actual criteria in the measurement of low temperatures. LUIGI ROLLA. Genoa. *Ann. chim. applicata* 2, 369–74(1914).—R. discusses the advantages and limits for the purpose of low temp. measurement, of the H, He and N thermometers, and the limits of application of the equation of state, $p v = A[1 + (B/v) + (C/v^2)(D/v^4) + (E/v^6) + (F/v^8)]$, and its simpler forms: $p v = A[1 + (B/v)]$ and $p v = A$; also the relationship of the Avogadro and Kelvin temp. scales. Behavior of magnetic susceptibility, of thermoelec. force and of elec. cond. at temps. near abs. zero are considered with regard to their utilization in temp. measuring instruments. R. also treats of the supercond. of Hg at near zero, and discusses low temp. thermometers based on vapor tension of O, H and other gases.

S. LEVY.

Numerical testing of some thermal relationships. W. HGRZ. Breslau. *Z. anorg. Chem.* 89, 397–400(1914).—H. tested a number of empirical relationships. The data used are themselves unsatisfactory. The relation $T\lambda = k$ (T = abs. m. p., λ = linear coeff. of expansion) held approx. for most metals tried, with k about 0.023; Bi and Sn were exceptions. The relation $L/\sqrt[3]{V}$ (L = mol. heat of evapn., V = mol. vol.) held approx. for certain compds., the values ranging from 1.53 to 1.72. The relation $Tc/M = k$ (T = abs. b. p., c = sp. heat, M = mol. wt.) did not hold even approx. The expression $T/d = n$ (T = abs. b. p., d = density, n = a const. which may be 2, 3, or $4\sqrt{2}$) expresses a fortuitous relationship true for some liquids only.

GEORGE W. MOREY.

Specific heats at constant pressure and at constant volume in liquids and vapors. STEFANO PAGLIANI. Palermo. *Nuovo cimento* 8, 157–88(1914).—P. gives (for temps. between 0° and 100°) the coeff. of expansion at const. pressure, the coeff. of increase of tension, the coeff. of isothermic compressibility, the specific heats at const. pressure (C_p) and at const. vol. (C_v) of the following liquids: H_2O , C_6H_6 , toluene, *m*-xylene, cymene, Me, Et, primary Pr, isobutyl and isoamyl alcohols, 3 hydrocarbons of petroleum, some mixed alcohols, and some other liquids, and compares them with figures obtained by Tyrer, whose conclusions are criticized. C_p increases with the temp. for most of the liquids—exceptions are CCl_4 (above 30°) and CS_2 (above 10°). Objection is made to Tyrer's statement that the variation is greater in liquids whose formula contains a larger no. of atoms. The difference between the 2 sp. heats for the liquid state and the vapor state in general is equiv. to the work of thermal expansion and is greater for the 1st state than for the 2nd. For H_2O and MeOH there is a temp. at which this difference is equal. The energy absorbed in the expansion of a liquid or vapor is used to a small extent in overcoming external work or pressure, but the greater part is used in internal work, required by the intermol. attraction, or in increasing the mol. energy. There are exceptions to Tyrer's general deduction that the difference between the 2 sp. heats increases continually with the temp. The author's work did not verify the relation of Tyrer: $(C_p - C_v)v^2/(dv/dt) = \text{const.}$ nor the general expression: $1/(dv/dt) - v(C_p - C_v) = 1$. With the extension of our knowledge relating to the physical properties of matter to a greater and greater number of compds., it is becoming more and more difficult to enunciate general laws applicable to substances varying in comp., in mol. condition, and in chem. functions. Equal conditions of temp. and pressure, and analogous variation of these magnitudes do not always bring about analogous effects in all compds., even in an equal state of aggregation; rather there is often observed difference of behavior in the variations of their characteristic physical properties with variation of the conditions of temp. and pressure, when these are within the same limit.

S. LEVY.

Heats of formation of acrolein and metacrolein. E. VOISENET. *Bull. soc. chim.* 17, 34-7(1915).—The mol. heat of combustion of acrolein (*A*) at const. vol. was found to be 393.14 Cal. (using Berthelot and Delépine's method (*Ann. chim. phys.* [7] 21, 1900)) and the heat of formation, 27.18 Cal., a value which is about 8 Cal. lower than that calcd. from the heat of formation of crotonic aldehyde (which is 41.9 Cal.). This "reserve energy," which is characteristic of the 1st member of this and other homologous aldehydic series, appears to account for the extreme reactivity of (*A*), especially in its polymerization reactions. The thermochem. equation for the prepn. of (*A*) by the dehydration of glycerol (*B*) is: (*B*) = 2H₂O + (*A*) + 3.78 Cal. When treated with HCl, (*A*) yielded CH₂ClCH₂CHO, which, when distd. with powdered KOH, gave rise to metacrolein, (CH₂:CH.CHO)₂, m. 45°, mol. heat of combustion at const. vol., 1169.19 Cal.; heat of formation, 92.65 Cal. LOUIS E. WISE.

The inapplicability of Boltzmann's equi-partition hypothesis to gases in a state of change of internal energy; and its bearing on the experimental determination of the specific heat of gases. J. G. STEWART. Univ. Birmingham. *Phil. Mag.* 28, 748-53(1914).—The matter is indicated by the title. A. T. CAMERON.

The variation of the triple-point of a substance with hydrostatic pressure. A. W. PORTER. *Phil. Mag.* 29, 143-9(1915).—It is shown, with special reference to the case of ice-water-steam, that the variation of the temp. of the triple-point with hydrostatic pressure is equal to the variation of the m. p. with hydrostatic pressure. The result is general in all triple-points and can be extended to the case of multiple-points. A. T. CAMERON.

The boiling points and critical temperatures of homologous compounds. A. FERGUSON. Univ. Coll., Bangor. *Phil. Mag.* 29, 599-608(1915).—A b. p. formula is proposed for the normal paraffins, $\log \theta = 1.929 (\log M)^{.4134}$, which covers the range of *n* from 4 to 17, where *n* is the number of C atoms, θ is the abs. b. p., and *M* the mol. wt., with an av. error of 0.64°. An equation, $\theta_c/\theta n^{.120} = 1.841$, where θ_c is the critical temp., holds for the normal paraffins between ethane and decane with an av. error of 0.33%. Eliminating θ between this second formula and any of the various b. p. formulas, empirical equations are obtained for the critical temps. of the normal paraffins. In particular, the equation $\log \theta_c = 0.2650 + 1.929 (\log M)^{.4134} - 0.120 \log n$ is in very close agreement with the observed facts. The b. ps. of the primary alkyl bromides are connected with those of the corresponding paraffins by the equation $\theta_B = \theta_P + 187.5/n^{.428}$, the mean error over the range of *n* from 3 to 8 being 0.73°. The similar formula for the primary alcs. $\theta_A = \theta_P + 331.1/n^{.744}$ gives their b. ps. over the range *n* = 3 to *n* = 10 with an av. error of 2.04°. A. T. CAMERON.

The van der Waals formula (and the latent heat of vaporization). T. C. SUTTON. Univ. Melbourne. *Phil. Mag.* 29, 593-9(1915).—It is shown that the formula for the latent heat of vaporization put forward by Applebey and Chapman (*C. A.* 8, 2296) is calcd. in essentially the same way as that of Mills and Young (*Sci. Proc. R. Dublin Soc.* 1910, 412), the former using a form of the van der Waals equation, the latter Biot's formula. A second modification of the van der Waals formula, $(p + a/v^2)(v - b - \gamma M) = RT$, where $\gamma = db/dt = \text{const.}$, is shown to give results equally in close agreement with the known data of latent heats, and to be preferable on theoretical grounds. This formula, and the derived expression for the latent heat, hold good for all the non-associated liquids examd. (using Young's figures), and for none of the associated liquids, affording a delicate test of association in a liquid. A. T. CAMERON.

The dielectric constant of liquid hydrogen iodide. HERMAN SCHLUNDT AND JULIUS UNDERWOOD. Univ. Missouri. *J. Phys. Chem.* 19, 338(1915).—New detns., using the Drude-Schmidt app. and colorless HI redistd. *in vacuo*, give 2.65 at 19°,

3.61 at -50° and 3.05 at -70° for the solid instead of 2.90 at 22° , 2.88 at -50° and 3.95 at -70° for the solid as previously reported by Schaefer and Schlundt (*C. A.* 4, 531). The accuracy of the value for the solid state is still somewhat in doubt.

O. A. RANDOLPH.

The dielectric constant of some organic solvents at their melting or boiling point. J. D. CAUWOOD AND W. E. S. TURNER. Univ. College, Wales. *J. Chem. Soc.* 107, 276-82(1915).—In order to det. the values at the b. p., measurements were made at a series of temps. and the values required were extrapolated while for the m. p. most of the values were obtained by a direct measurement at or within 1° of the m. p. Nernst's app. was used for the detns. with C_6H_6 at 17° as the standard in the most cases. All of the substances used were purified. The results are as follows: C_6H_6 , m. 5.5° , b. 80° , $k_{m.p.}$ 2.275, $k_{b.p.}$ 2.170; $C_{10}H_8$, m. 80.5° , $k_{m.p.}$ 3.22; cyclohexane, m. 4.5° , $k_{m.p.}$ 2.075; *o*- $ClC_6H_4NO_2$, m. 33° , $k_{m.p.}$ 17.8; *p*- $ClC_6H_4NO_2$, m. 83.5° , $k_{m.p.}$ 12.7; *p*- $Cl_2C_6H_4$, m. 52.1° , $k_{53.0^{\circ}}$ 2.82; *p*- ClC_6H_4Me , m. 7.4° , $k_{m.p.}$ 6.35; *p*- BrC_6H_4Me , m. 28° , $k_{m.p.}$ 5.07; *p*- IC_6H_4Me , m. 35° , $k_{m.p.}$ 4.40; *p*- $O_2NC_6H_4Me$, m. 52° , $k_{m.p.}$ 18.44; $CHCl_3$, b_{716} 60.9 , $k_{61.2^{\circ}}$ 4.13; $CHBr_3$, m. 7.5° , k_8° 4.58; *p*- $MeC_6H_4NH_2$, m. 43.7° , $k_{44^{\circ}}$ 5.40; Ph_2NH , m. 52° , $k_{m.p.}$ 3.30; C_6H_5N , b_{716} $114.0-114.2^{\circ}$, $k_{b.p.}$ 9.5; veratrole, m. 22.5° , $k_{m.p.}$ 4.47; benzil, $k_{98^{\circ}}$ 4.14; isoamyl alc., b_{716} $128.3-128.4^{\circ}$, $k_{b.p.}$ 5.7; Me_2EtCOH , b_{716} $101.7-102.2^{\circ}$, $k_{b.p.}$ 5.7; methyl succinate, m. 19.5° , $k_{m.p.}$ 5.12; methyl *p*-toluate, $k_{33^{\circ}}$ 4.28.

O. A. RANDOLPH.

The electron theory of metallic conduction. II. G. H. LIVENS. *Phil. Mag.* 29, 425-32(1915); cf. *C. A.* 9, 881.—A mathematical paper harmonizing the views of Drude and Thomson on the interaction of electrons and atoms with those of Lorentz.

A. T. CAMERON.

The photoelectric effect. III. O. W. RICHARDSON AND F. J. ROGERS. *Phil. Mag.* 29, 618-23(1915).—The previous results of Compton and Richardson for Pt, Al, Na and Cs (*C. A.* 8, 9) are expressed in abs. values and compared with those of Werner (*C. A.* 7, 2153) and of Pohl and Pringsheim (*C. A.* 8, 277).

A. T. C.

The contact difference of potential of distilled metals. F. SANFORD. Stanford Univ. *Phil. Mag.* 29, 623-4(1915).—An explanation is suggested for some of Hughes' results (*C. A.* 8, 3744). When a section of a glass tube is heated to 100° or less it becomes electronegative to the colder parts of the same tube; the process is slow. In Hughes' expts. the glass must have been considerably heated over the regions upon which the metallic films were condensed, probably became negatively electrified, and accordingly lessened the electropositive induction effect of the metallic films. As the glass cooled its charge diffused slowly, and the metallic films appeared to become more electropositive. Admission of a trace of air would enable the negative charge on the glass to diffuse more rapidly.

A. T. CAMERON.

On the statistical relations of radiant energy. G. H. LIVENS. Univ. Sheffield. *Phil. Mag.* 28, 648-64(1914).—A free interpretation of the simplest suitable test of convergency leads to a formula which is identical with Planck's in probably all attainable regions of the spectrum.

A. T. CAMERON.

The Corbino effect. E. P. ADAMS AND A. K. CHAPMAN. Princeton Univ. *Phil. Mag.* 28, 692-702(1914).—The Corbino effect (that when a uniform radial elec. current flows through a circular metallic disk in a magnetic field normal to the plane of the disk, there is produced a circular elec. current such that the current density is inversely proportional to the radius) has been measured for a large number of metals and compared with the Hall effect. The Corbino effect would seem to be the fundamental galvanometric effect rather than the Hall effect, since the free transverse boundaries necessary in the latter are wholly absent in the former. The 2 are closely related, and

the fundamental explanation of one will explain the other. In all the metals tested the 2 effects have the same sign, but there is a marked difference in the relative magnitudes, the Hall effect showing greater differences. The mean free path of the electron in a number of metals is given (varying from 8.9×10^{-8} in Al, to 4.6×10^{-8} in Bi).

A. T. CAMERON.

Reflective power and dielectric constants of non-conducting solid substances and some liquids. H. RUBENS. *Sitzb. kgl. preuss. Akad. Wiss.* 1915, 4-20; cf. *Ibid* 1903, 269, 410; 1910, 26, 1122; C. A. 6, 708, 1252; 7, 1838; 8, 2302.—Continuation of the earlier work. In this paper the reflection of rest-rays from CaF_2 , NaCl, KCl, KBr, KI, and TlBr, corresponding to wave lengths of 23, 33, 52, 63, 83, 94 and 117 μ , and from Hg with a wave length of 300 μ has been measured for 25 new substances, including H_2O , H_2SO_4 (3 concs.) and glycerol. The most of the substances were inorg. salts. TiCl, TlBr and TlI have large dielectric consts., 35, 42 and 30, resp.; PbCl_2 , 42. Most of the other solids had dielec. consts. below 10. Diagrams are given showing the % absorption of each substance for each wave length.

E. B. MILLARD.

Color and constitution. E. C. C. BALY. Liverpool. *J. Soc. Dyers Colourists* 31, 39-46(1915).—As a measure of color the author takes the absorption of light in the visible and invisible regions of the spectrum. He attacks the quinonoid theory, instancing the cases of diphenylvioluric acid and its salts, in which that theory breaks down. In its place B. offers a theory of color based on the same grounds as his previous theory of fluorescence (C. A. 7, 2348). Color change then is due not to a change in mol. structure but to an opening up of the fields of force of the mol. which is evidenced by the changes in the selective absorption. This opening up may be caused by solvents, light or chem. reagents. It may take place in successive stages and there is a relation between the frequency of the light waves absorbed at the different stages and those absorbed by the parent substance. No direct exptl. evidence is adduced but B. applies the theory to explain the cases of β -methoxynaphthalene, phenol, the diphenylviolurates and the aminoazo compds.

B. B. STODDARD.

Cause of the phosphorescence of fluorspar. R. FORMALS. Berlin. *Chem. Ztg.* 38, 1111(1914).—Several varieties of phosphorescent fluorspar were analyzed. Apparently the phosphorescence is due to the oxidation of traces of finely divided As sulfide. Ignited fluorspar does not show the phenomenon. The addition of a trace of As sulfide to powdered feldspar causes phosphorescence on heating.

E. J. C.

Laws of series spectra. J. W. NICHOLSON. *Proc. Roy. Soc. London (A)* 91, 255-72(1915).—Mathematical. The limit of series with many lines, for which a Hicks formula is already known, can be calcd. with extreme accuracy by a new method. The interferometer measurements of the leading lines of the He spectrum enable the best form of series to be obtained, and this form is an extension of that of Rydberg, dependent upon $m + \mu$, and not m . The value of Rydberg's const. 109670.2 given by Curtis for H is the true value for the arc spectrum of He, and is in fact a rigorous const. for arc spectra. Spark spectra are not treated. The Rydberg-Schuster law of limits is exact for He. It seems probable that μ is a simple fraction whose denominator is a multiple of 5 as Halm has suggested. It is exactly 0.7 for the Sharp series of He.

The variation with temperature of the electric furnace spectra of vanadium and chromium. A. S. KING. Mt. Wilson. *Astrophys. J.* 41, 86-115(1915).—The study of spectra by means of the tube furnace (cf. C. A. 7, 1838; 8, 3264; 9, 15) has been ex-

tended to V and Cr between the ranges λ 3150– λ 6850 and λ 3550– λ 7000, resp. The V spectrum is similar in its behavior to that of Ti and the Cr to Fe. The Cr lines which appear at the lower temp. usually strengthen slowly at the higher temps. Certain Cr lines, diffuse in the arc in air, are resolved into sharp components in a vacuum source, arc or furnace. A large number of the furnace lines are relatively weak in the arc. The extension of the spectrum into the ultraviolet increases as the temp. rises. Self-reversal is much greater with decreasing wave length. The absence of the banded spectra indicate that these are due to the oxides in the V and Cr arcs. F. A. H.

The different character of spectrum lines belonging to the same series. T. ROYDS. *Astrophys. J.* **41**, 154–61(1915).—It has been generally assumed that spectrum lines belonging to the same series are similar in character and behavior under varying exptl. conditions. The lines of the first subordinate "triplet" series of Ba, however, change. The first members of the series are all unsymmetrically widened toward the red, the second members and probably all succeeding members are unsymmetrically widened toward the violet. There seems no doubt that the series is a real one and the difference in behavior seem equally certain. There are indications that the same effect exists in the corresponding series of Ca, but the first members are in the infra-red and their character is not known. The Sr series is quite normal. Inconsistencies in published results on pressure shift in the arc are probably due to a superimposed density effect. F. A. HARVEY.

The Stark-effect for canal rays. H. duBOIS. *Verslag Akad. Wetenschappen* **23**, 828(1914).—Stark (*Ann. Physik.* **43**, 965–1045(1914); cf. *C. A.* **8**, 2103) first observed that an electrostatic field has an effect on the spectrum lines of luminescent vapors, in the case of H_2 , He, and Li lines emitted by canal rays. The max. spreading obtained was approx. 2μ . W. Wien found a spreading for H_2 lines of the order 0.5μ , which is much greater than the spreading in the ordinary Zeeman effect. The Zeeman effect and the Stark effect appear to be 2 separate, but closely related phenomena, both proportional to the field. Luminescent vapors give rise to a passage of electricity, which amounts to several milli-amps. DuB. desired to study a purely dielec. displacement. He introduced a plate of synthetic ruby, 3 mm. in thickness, ground parallel in one case, and normal in another case to the crystal axis. Such a plate shows selective absorption, and possesses a high dielec. const. To observe the occurrence of a longitudinal effect, brass plates, provided with a slit were fastened to both sides of the ruby plate, which was then connected to the electrostatic machine, and immersed in liquid air. With a p. d. of 200 kilovolts per cm. no appreciable effect was observed. A plate of the monoclinic $Nd(NO_3)_3 \cdot 6H_2O$, 1 mm. in thickness, ground normal to one of the axes was substituted for the ruby. At the temp. of -190° the absorption bands again showed no effect of the elec. field. A soln. of salt in EtOH (-118°) and in amyl alc. (-134°) also yielded negative results. P. VAN DER MEULEN.

The theories of rotational optical activity. G. H. LIVENS. *Phil. Mag.* **28**, 756–7 (1914).—Reply to Bruhat (*C. A.* **8**, 3747). L. insists on the incompleteness of Drude's theory. A. T. CAMERON.

Displacements in certain spectral lines of zinc and titanium. G. V. MORROW. *Phil. Mag.* **29**, 394–407(1915).—The results show that the wave lengths of the lines in the spectra of the metallic elements are not const., but that under certain conditions they experience displacements towards the red. The wave lengths of lines in the spark spectrum of the pure metal are in general greater than those in the arc spectrum, but the difference alters for the various metals and for the different lines of the metals. In the arc spectrum of the pure metal the lines are displaced by increasing the current, if the point at which the element vaporizes be high enough for the increase in current to produce an increase in the density of the vapor. The presence

in the arc or spark of atoms of another element appears to have no influence on the wave lengths of the lines of the substance being examd., the wave lengths obtained depending on the partial density of the substance itself. The measurements show clearly in many cases that through over-exposure of the plate errors may be produced in the results, since on increasing the time of exposure, and consequently increasing the ppt. of Ag on the plate, an apparent alteration can be found in the wave length of lines which are unsymmetrically broadened. A. T. CAMERON.

Condensation nuclei produced by the action of light on iodine vapor. H. PEALING. S. African Coll., Cape Town. *Phil. Mag.* 29, 413-9(1915).—A continuation of the expts. of Owen and Pealing on this subject (*C. A.* 5, 2027) and a reply to Ramsauer's criticism (*Phil. Mag.* 23, 849(1912)) of their theory of explanation. P. confirms the previous expts., and finds that the production of nuclei when light falls on a mixt. of moist air or O and I vapor contained in a freshly cleaned glass vessel, and the facilitation of this formation of nuclei by the passage of I-laden air into the app. through a plug of glass-wool, are as far as the exptl. facts show explicable on the assumption that the production of nuclei is due to some chem. action, and that this takes place between I and H₂O vapor and O caused by a catalytic action of the glass. A. T. C.

A direct method of determining the radiant luminous efficiency of light sources. E. KARRER. United Gas Improvement Co., Phila. *Lighting J.* 3, 27, 37-8(1915); *Phys. Rev.* 5, 189-211(1915).—K. has devised a special radiation filter, consisting of 3 quartz cells 1 cm. thick arranged in series and containing the following solns., resp.: (1) 57.519 g. CuCl₂·2H₂O in 1 l. H₂O, (2) 1.219 g. K₂Cr₂O₇ in 1 l. H₂O, (3) 9.22 g. FeCl₃·6H₂O in 1 l. H₂O. The absorption of the filter has been so adjusted that the part of the total radiation which passes through at any wave length will be proportional to the visibility or luminous effect at that particular wave length. Thus, if radiations having equal energy at every wave length were used, the curve, showing the amt. of radiation passing the filter at each wave length, would correspond very nearly with the visibility curve of an equal energy spectrum as detd. by H. E. Ives. This curve starts from 0 at 0.42 μ , reaches a max. at 0.55 μ and falls to 0 again at 0.70 μ . If the radiations from any source are measured by a total radiation pyrometer or bolometer, first without the filter, and second with the filter, the ratio of the second reading to the first will be the radiant luminous efficiency. Some values of this quantity for common light sources have been detd. as follows: Open gas burner 0.19%, standard candle 0.24%, C filament at 4 w. per c. p. 0.45%, Welsbach mantle 0.80%, Nernst glower 1.08%, W filament at 1 w. per c. p. 1.99%, W filament type C at 0.65 w. per c. p. 2.93%, Hg arc (Pfund type) 30.0%. Further experiments with liquid helium. M. Preliminary determination of the specific heat and thermal conductivity of mercury at temperatures which may be obtained with liquid helium, together with some measurements of thermo-electromotive force and resistance in connection with these investigations. H. KAMERLINGH ONNES AND F. HOLST. *Verslag. Akad. Wetenschappen* 23, 703-10(1914).—Measurements of the sp. heat and thermal cond. of Hg are especially desirable on account of the discontinuity in the resistance of Hg at 4.19° K. Preliminary measurements of the thermo-e. m. f.s of Ag, Au, Pt, Pb, Fe, constantan and Au + 0.476% Ag against Cu at temps. between 2.26 and 81° K., showed that for all of these metals, the thermo-electric power (dE/dt) becomes very small at temps. below 20° K.; this is in agreement with the conclusions of Nernst and of Keesom that dE/dt becomes zero at the abs. zero of temp. Thermoelements are, therefore, not suitable for use at He temps. Resistance thermometers of constantan or of manganin, however, have been found especially suitable for temps. from 20° down to 2.26° K. The sp. heat of Hg was detd. by heating electrically a small block of the solid metal suspended in a vacuum, and measuring the resulting rise in temp. The mean sp. heat between 4.26 and 6.48° K. is 0.00142 cal. per g. per degree; between 2.93 and 3.97° K., 0.000534 cal. (accuracy 10%). It appears then that the sp. heat shows no sign of discontinuity such as is found for the elec. resistance. The thermal cond. of Hg was detd. by measuring, with 3 constantan resistance thermometers, the temp. gradient along a column of Hg contained in a small double-walled tube. The results are: at 4.5-5.1° K., $k = 0.27$ cal. per cm. per sec.; at 3.7-3.9° $k = 0.40$. Therefore, for the thermal cond. also, no discontinuity occurs at 4.19° K.

L. H. ADAMS.

The reduction of iron oxides by platinum, with a note on the magnetic susceptibility of iron-bearing platinum. R. B. SOSMAN AND J. C. HOSTETTER. *J. Wash. Acad.* 5, 293-303(1915).—Pt acts on both hematite and magnetite at 1200° under low pressures of O, absorbing Fe and giving off O. It also reacts with magnetite in the same way at 1600° and at the usual atm. pressure of O. (Hematite is not stable in air at 1600°, but goes over into magnetite.) On the other hand, it is well known to analysts that Pt crucibles in which Fe_2O_3 is ignited in air for weighing in analytical procedures take up no such amts. of iron as were found to be absorbed under the conditions just described. The reason for these differences of behavior is readily found in the phase rule and the relations of Fe and Pt in their alloys. The results explain the very common occurrence of small amts. of Fe in Pt, since Pt will exercise its reducing action on any material containing Fe oxides with which it comes in contact provided the temp. is sufficiently high. At low temps., on the other hand, and with abundant access of atmospheric O, no appreciable reduction is to be expected. The magnetic pull exerted by an electro-magnet on a sample of iron-bearing Pt gives a qual. indication of the presence of iron, but no quant. measure of the amt. present.

The radium content of water from the Gulf of Mexico. STEWART J. LLOYD. *Am. J. Sci.* 39, 580-2 (1915).—Two successive detns. on the same sample of sea-water from the Gulf of Mexico gave for the Ra content of the water the mean value of 1.7×10^{-12} g. per l. The corresponding values found by Eve (*C. A.* 3, 2532), Satterly (*C. A.* 6, 3057) and Joly (*C. A.* 2, 2501) were 0.9×10^{-12} , 1.0×10^{-12} and 17.0×10^{-12} g., resp. Omitting the last detn., the mean value of the others amounts to 1.2×10^{-12} g. of Ra per l. This would correspond to a total amt. of Ra in the sea of somewhat more than 1400 tons. The U which the water should contain in order to maintain this quantity of Ra amounts to from 0.003 to 0.005 mg. per l. W. H. ROSS.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

The smelting of dross in the electric furnace. RAYMOND S. WILE. *Trans. Am. Electrochem. Soc.* 26, 252-5 (1915); *Mining Eng. World* 42, 501-4 (1915).—A small elec. furnace with a capacity of 1 ton per day was built to smelt the finely divided Sn crystals resulting from an electrolytic Sn recovery process. It consists of a vertical cylindrical chamber 36 in. high by 9 in. diam., with 2 C electrodes near the bottom between which a fusible slag forms the conducting and heating element. To start the furnace, some broken slag is put in and heated with an arc until it is hot enough to conduct. The electrodes are drawn apart and more slag is put in and melted, until a sufficient slag bed is formed. The upper part of the furnace is then filled with moist Sn crystals mixed with a little C and SiO_2 . The Sn melts, sinks through the slag and forms a layer at the bottom, whence it is tapped out from time to time. The best comp. for the slag has been found to be 67% SiO_2 , 17% CaO , 16% Na_2O . However, it may vary several % from this comp. and still work properly. The temp. of the slag must be kept at about 1650° to prevent loss of Sn. At this temp. the loss of Sn in the slag is only about 0.5%, while at lower temps. it may reach 17%. It was found that Sn dross could be satisfactorily smelted in this type of furnace and 2 larger furnaces requiring 800-1000 amps. d. c. at 220 v. were constructed for that purpose. Although this process is more costly than the reverberatory furnace process, it has the advantage

of yielding a product which does not need to be refined again. Practically all of the Fe and Cu in the dross are dissolved and removed by the slag. If Zn is present, it is volatilized and may be recovered as ZnO. Analytical control of the charge is necessary, in order to keep the comp. of the slag correctly adjusted. For a dross containing about 50% Sn, 10% Zn, and 14% Fe, the power required will be about 700 kw. hrs. per ton of Sn. The same type of furnace can be used also for refining various Zn waste products, such as 80% Zn + 20% Fe alloy from the galvanizing process, but as yet not enough exptl. work has been done to give a definite idea of its performance with such material.

A. B. GLADDING.

Working up of the materials obtained by the electrolysis of the residual liquors from the manufacture of potash salts. DIETZ. *Z. angew. Chem.* 27, 1, 569-72(1914); *J. Soc. Chem. Ind.* 34, 26.—Besides Br and H, Cl is obtained at the anode, an incrustation of $Mg(OH)_2$ on the cathode, and a ppt. of Mg oxychloride in the cathode compartment. The incrustation is preferably treated separately from the ppt., and by washing and heating may be profitably converted into oxide or hydroxide free from Cl. The oxychloride may be treated by the Leopoldshall process with steam to produce magnesia and HCl; but preferably it is centrifuged and ignited to the anhydrous form, $MgCl_2 \cdot 6MgO$, which is used in magnesia cement. The Cl may be converted into HCl either by decomposing the chlorides of Zn or Al with steam, and then regenerating the chloride by passing Cl and H over the hydroxide thus formed (cf. Hoppe, *Fr. Pat.* 352,419, Mar. 15, 1905), by Patacky's method (*Ger. Pat.* 114,129; *Brit. Pat.* 1,831, Jan. 29, 1900), or by Nagel's method (cf. *C. A.* 6, 1211). Preference is given to the first-named process.

The silver voltmeter. G. A. HULETT AND G. W. VINAL. *J. Phys. Chem.* 19, 173-92(1915); see *C. A.* 9, 412.

A. B. G.

Reproducibility of the cadmium electrode. F. H. GETMAN AND V. L. GIBBONS. Bryn Mawr, Pa. *J. Am. Chem. Soc.* 37, 953-70(1915); cf. *C. A.* 5, 3749; 8, 3261; 9, 267.—Expts. were made with cells of stick Cd and electrolytically deposited Cd, using MeOH as the solvent and CdI_2 as electrolyte, with a Lippmann electrometer and the Poggendorff compensation method, at 25°. The e. m. f. of the cell $Cd^+ | 0.13 N CdI_2 | 0.013 N CdI_2 | Cd^-$ in MeOH was much higher for deposited Cd than for the sticks. Several electrodes were measured against $Hg | Hg_2SO_4 (0.1 N CdSO_4) |$ and the gray cryst. Cd was shown to be the stable form. Polished surfaces of Cd were shown by the use of photomicrographs to change when immersed in 0.2 N CdI_2 soln. at 5°. Neither freshly cast Cd nor spongy Cd gave reproducible e. m. fs. with conc. cells in MeOH, and cast rods were not satisfactory in aq. solns. of CdI_2 . Rods which had become gray by standing in CdI_2 solns. gave const. e. m. fs. against non-polarizable electrodes. Cryst. electrolytic deposits gave a (const.) higher e. m. f. than gray ones; amalgamated electrodes were not reproducible. Attempts to inoculate the fresh Cd surface with gray Cd showed that the change was extremely slow. The change to gray was due to a deposit on the surface, not to a pitting of it.

E. B. MILLARD.

Single cell gold plating. FRANCIS L. MCALOON. *Metal Ind.* 12, 510(1914).—There are 3 important principles to be observed in single cell Au plating. (1) The energy for electrolysis is derived from the action of the NaCl soln. upon the Zn. The soln. must be hot and concd. to get the greatest action. (2) The rate of deposition is very slow as compared with that in the external energy cell. Hence it is necessary to eliminate from the plating soln. any chemicals which would tend to attack the work. (3) Since the plating soln. is always slightly alk., it is necessary to have the work free from the slightest suggestion of tarnish when it goes into the soln. Such tarnish may result from leaving the work too long in the cleaning soln. A single cell soln., which has been proven good by long experience, is made by dissolving 3 dwts. Au (in form of

fulminate) + 1 oz. $\text{K}_4\text{Fe}(\text{CN})_6$ + 0.5 oz. $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ in 1 gal. H_2O . The use of NH_4Cl instead of NaCl in the outer compartment of the cell is not economical. The practice of lifting the Zn plates from the cell when not in use does not save enough to pay for the extra work.

Nickel-plated aluminium. J. CANAC AND E. TASSILLY. *Eng. Mag.* **49**, 273-4 (1915); see *C. A.* **8**, 2529. I. C. M.

Formation of aromatic hydrocarbons by the electrolysis of salts of aromatic carboxylic acids. C. SCHALL. *Z. Elektrochem.* **21**, 69-73(1915).—Attempts to synthesize aromatic hydrocarbons by the Kolbe electrolytic process have up to the present been unsuccessful. Earlier expts. by S. and co-worker (*Z. Elektrochem.* **5**, 256; and *C. A.* **8**, 467) on the electrolysis of K *o*-nitrobenzoate in molten *o*-nitrobenzoic acid apparently yielded a trace of *o*-dinitrodiphenyl. The present communication describes the electrolytic decomp. of a hot soln. of the *p*-acid in pure acetic anhydride, which yielded a minute quantity of *p*-dinitrodiphenyl (recognized by its conversion into benzidine). Formation of this is assumed to occur through a composite electrolysis of the K nitrobenzoate and acetate in the acetic anhydride soln., the acetate being formed by a primary thermal decomp. No aromatic hydrocarbon could be obtained by application of thermal effects alone.

The high-tension test. W. P. WOODWARD. *Gen. Elec. Rev.* **18**, 398-400(1915).—Each of the 3 testing sets consists essentially of a high-tension transformer with regulating outfit and the necessary spark-gaps, condenser resistances and reactances. During test, control is obtained by means of rheostats in both the motor and the generator fields, so that the frequency as well as the voltage is completely under the control of the operator. The burden of the testing is carried on by sphere-gaps of various sizes, yet needle-point gaps are available. An oil tank of 36,000 gal. capacity is conveniently located and the oil is under uniform temp. control for such tests as require oil immersion. In the 750,000 v. outfit the principal unit is a 500-kva., 750,000-v., 60-cycle transformer. Tests are made on varnishes, plastics, and textiles in advance of their application to various machines. Several illustrations are given. I. C. M.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Oxidation of sulfides with potassium iodate. R. S. DEAN. Rolla, Mo. *J. Am. Chem. Soc.* 37, 1134-7(1915).—For CdS, PbS and ZnS, the equation was found to be $3\text{XS} + 3\text{KIO}_3 + 12\text{HCl} = 3\text{XCl}_2 + 2\text{S} + \text{H}_2\text{SO}_4 + 3\text{KCl} + 3\text{ICl} + 5\text{H}_2\text{O}$. When a smaller conc. of HCl was present the amt. of iodate corresponded more nearly to $2\text{XS} + \text{KIO}_3 + 6\text{HCl} = 2\text{XCl}_2 + 2\text{S} + \text{KCl} + \text{ICl} + 3\text{H}_2\text{O}$, where X stands for the metals above. Expts. show the progress of the reaction in the presence of varying amts. of HCl.

E. B. MILLARD.

Cuprous salts of oxygen acids and a new method for preparing cuprous salts. Preliminary paper. L. C. DANIELS. Lexington, Ky. *J. Am. Chem. Soc.* 37, 1167-71 (1915).— Cu_2SO_3 was sprinkled little by little into a hot soln. of an excess of oxalic acid. A brown solid appeared and much SO_2 was evolved. It was found to contain 50.69% Cu, corresponding closely with the formula $\text{Cu}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, but the reducing power with KMnO_4 was much too high for this formula. A closer agreement was found for the formula $\text{Cu}_2\text{H}_2(\text{C}_2\text{O}_4)_4$. What was apparently the same compd. could be prep'd. by digesting Cu_2O with $\text{H}_2\text{C}_2\text{O}_4$. E. B. MILLARD.

Dehydration products of gypsum. R. GRENGG. Vienna. *Z. anorg. Chem.* 90, 327-60 (1914).—Chiefly confirmation of facts given in the literature. Gypsum is transformed on gentle heating into rhombic $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$, the process involving a recrystn. with formation chiefly of needle-like forms; at 140° sol. anhydrite begins to form, and it forms solid soln. with the $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$. On further heating insol. anhydrite forms, and stronger ignition causes decompn., the CaO produced probably being taken into solid soln. by the insol. anhydrite; the substance, as the temp. is raised, first becomes amorphous, then cryst. "Estrich" gypsum contains a large excess of CaO. GEORGE W. MOREY.

Behavior of certain hydrazine salts on decomposition by heat. J. W. TURRENTINE. Cornell Univ. *J. Am. Chem. Soc.* 37, 1105-14 (1915).—The decomp. of hydrazine monochlorate by heat in neutral aq. solns. yielded no HN_3 ; HN_3 was formed, however, in H_2SO_4 soln. The corresponding di-salt yielded HN_3 both in the presence and absence of H_2SO_4 . The mono- and diperchlorate of N_2H_4 yielded no HN_3 either in acidified or unacidified solns. When the dry crystd. salt was decompd. by heat in a current of CO_2 , HN_3 was produced from the latter but not from the former. Both yielded gaseous Cl, N and O, and Cl and OH ions. The mono- and disulfates, under similar conditions, gave off H_2O , H_2S , SO_2 and S, but no HN_3 . HN_3 was not oxidized on boiling with H_2O_2 in alk. soln.; it may be sepd. from sulfites in this way, and this principle has been applied in a method (described) for detecting HN_3 in presence of SO_2 . E. B. M.

Electrochemical oxidation of hydrazine sulfate and ammonium hydroxide. J. W. TURRENTINE AND J. M. OLIN. Cornell. *J. Am. Chem. Soc.* 37, 1114-22 (1915); cf. preceding abst.—A soln. of $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ (satd. in the cold) in 5% H_2SO_4 was electrolyzed between Pt sheet electrodes at its b. p. with high c. d., but no HN_3 was formed; none could be formed by using more H_2SO_4 . With high concs. of H_2SO_4 the main products were $\text{H}_2\text{S}_2\text{O}_8$ and O_2 . When a small wire anode was used in 10% H_2SO_4 , and the soln. was kept at 0° , some HN_3 was formed. The oxidation was a product of a secondary reaction of the persulfate ion (formed at the anode) on the hydrazine ion. NH_4OH , in the presence of NaCl (added in small amts. during the electrolysis) and glue, and with low c. d., was oxidized to N_2H_4 . E. B. MILLARD.

Description of a new compound, hydrazine diperchlorate. J. W. TURRENTINE AND A. C. GILL. *J. Am. Chem. Soc.* 37, 1122-8 (1915).—The reaction used was $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4 + \text{Ba}(\text{ClO}_3)_2 = \text{N}_2\text{H}_4 \cdot 2\text{HClO}_3 + \text{BaSO}_4$. The compd. crystallizes with 2 mols. of H_2O , forming colorless tabular orthorhombic crystals. Crystals of the mono-perchlorate are probably monoclinic. The di-salt gives 4 ions in dil. soln., and is strongly acid. The substance explodes when struck with a hammer. E. B. MILLARD.

Preparation of chlorides of silicon. F. S. KIPPING. *Chem. News* 111, 135 (1915).—A criticism of a paper by Martin (*C. A.* 9, 1017). Martin prepared the tetrachloride and other chlorides of Si from Fe-Si, without reference to previous work by Warren who originated the method (cf. *Chem. News* 66, 113). W. H. S.

Isolated crystals of selenium of the second and fifth systems, and the physical conditions determining their production. F. C. BROWN. *Phys. Rev.* 5, 236-7 (1915).

—Rhombohedral, hexagonal and monoclinic crystals of Se were produced by subliming amorphous Se after it had been melted. At temps. between 190° and 220° large quantities of hexagonal needles were obtained, and at the highest temp. various undetd. combinations of forms appeared. If kept at a temp. of 170° for 3 months, lamellar monoclinic crystals were produced. Both crystal forms were produced at a lower temp. in a vapor of Se than was required in the presence of air at normal pressure. It is assumed that the v. d. as well as the temp. is a detg. factor in the control of crystal forms. The electrical, photo-electric and electro-mechanical properties of crystals of each system do not exhibit any decided differences.

W. H. S.

New observations on iodic salts. FR. FICHTER AND HANS KAPPELER. *Basil. Z. anorg. Chem.* 91, 134-44(1915).—(Expts. by EDUARD KRUMMENACHER). By the oxidation at low temp. of I dissolved in HClO_4 by a current of dry ozone, *iodic perchlorate*, $\text{I}(\text{ClO}_4)_2 \cdot 2\text{H}_2\text{O}$, was obtained; decompd. on warming to room temp. by auto-oxidation, decompd. by H_2O , indifferent to organic solvents, not explosive. (Expts. by LOUIS HELFFER). *Iodic sulfate*, $\text{I}_2(\text{SO}_4)_3$, was prepd. by heating $(\text{IO})_2\text{SO}_4 \cdot 0.5\text{H}_2\text{O}$ with SO_3 in a sealed tube at $100-120^{\circ}$; the large light yellow crystals are instantly decompd. by moisture. $\text{I}(\text{IO}_3)_2$ was prepd. by heating I dissolved in anhydrous HPO_4 . The compds. HI_2O_2 and $\text{I}_4\text{O}_{13}\text{SO}_3$ described in the literature probably do not exist.

GEORGE W. MOREY.

Formation of crystalline hematite during the burning of bricks. FRANK HUGHES. *Cairo Sci. J.* 8, 188-9(1914).—A brilliant cryst. deposit which collected in crevices between burnt bricks was in the form of very thin plates and had all appearance of a sublimate. An analysis of the cryst. portion showed 97% Fe_2O_3 and proved it to be similar to the form known as "micaceous hematite." These crystals could only have occurred as a result of slow deposition from gases and the Fe chlorides have been shown to be volatile in an inactive atm. Attempts in the lab. to obtain a cryst. Fe oxide by passing a mixt. of HCl gas and air over heated Fe compds. have been unsuccessful, probably because a sufficiently high temp. was not obtainable.

R. L. SIBLEY.

Reduction of iron oxides by platinum (SOSMAN) 2. Transformation of the trichlorides of chromium and titanium (HEYDWEILLER) 2.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Use of the interferometer for the analysis of solutions. L. H. ADAMS. Washington, D. C. *J. Am. Chem. Soc.* 37, 1181-94(1915).—A. presents a brief description of the principle and mode of operation of the interferometer. It may be used to det. the single varying constituent in a mixt. or soln. with ease, rapidity and very great accuracy. Error due to difference in optical dispersion can be obviated by use of the methods discussed.

E. B. MILLARD.

Calculation of the capacity of smooth filters. L. WOLTER. *Chem. Ztg.* 38, 1243 (1914).—From the known diam. (d) of a smooth filter, the capacity (C) can be calc. when the funnel angle is 60° by the formula, $C = (\pi d^3/192) \sqrt{3}$. Assuming that the filter is to be filled to within 0.5 cm. of the edge, becomes the formula $C = [\pi(d-1)^3/192] \sqrt{3}$. A table showing calc. capacities of filters of usual sizes is given.

E. W. BOUGHTON.

A precipitant for ammonia. (A substitute for Nessler's reagent). S. S. GRAVES. New York City. *J. Am. Chem. Soc.* 37, 1171-81(1915).—A sufficient excess of NaCl prevents the formation of HgO when an alkali carbonate is added to HgCl_2 soln., by

driving back the dissociation of the complex Na_2HgCl_4 . A soln. composed of 50 cc. satd. HgCl_2 , 15 g. NaCl , 35 cc. satd. Li_2CO_3 soln. and 65 cc. H_2O proved to be a satisfactory reagent, for it pptd. a white cloud with NH_3 and could be used nephelometrically to det. NH_3 . A small amt. of sol. starch was added as a protective colloid for the NH_4 complex formed. The application of the reagent to micro-Kjeldahl detns. and other biological problems is discussed. E. B. MILLARD.

Nessler reagent. G. FRERICHS AND E. MANNHEIM. *Apoth. Ztg.* 29, 972-4 (1914).—The following method for prepg. this reagent is suggested: In a 100 cc. flask containing 3 g. H_2O dissolve in the cold 2.5 g. KI and 3.5 g. HgI_2 , then add 100 g. 15% KOH and allow the mixt. to stand several days for the eventual deposition of a slight ppt. due to traces of NH_3 usually present in the alkali. Decant the clear soln. from the ppt. Should it seem desirable to render the reagent immediately available, add a small quantity of talc and pass the liquid through a small sand filter. In testing distd. H_2O , use 10 cc. of the latter to about 1-2 cc. of reagent; in testing hexamethylenetetramine for NH_4 compds., use about 10 drops reagent to 10 cc. of soln. (1:19) under exam. W. O. E.

Method for the titration of small amounts of halides. F. C. McLEAN AND D. D. VAN SLYKE. *J. Am. Chem. Soc.* 37, 1128-34 (1915).—The halide was pptd. in the presence of free HNO_3 by an excess of 0.04 or 0.02 *N* standard AgNO_3 , the ppt. filtered off, and the excess Ag detd. by titration with 0.02 *N* KI in the presence of a dil. soln. contg. $\text{Na}_2\text{C}_4\text{H}_4\text{O}_7$ (citrate), NaNO_3 , and sol. starch. With one drop of KI in excess a distinct color was obtained. Amts. of halide not greater than 0.5 mg. were detd. to 1 part in 1000. E. B. MILLARD.

Notes on permanganate titrations. HENRY ZIEGEL. *Chem. Analyst* 12, 211-2 (1915).—In titrating Fe with KMnO_4 the concn. of free acid should not exceed 5% by vol. Solns. of FeCl_3 should not be boiled as FeCl_3 is appreciably volatile with steam.

H. M. LANCASTER.

Determination of boron in iron. J. M. LINDGREN. Urbana, Ill. *J. Am. Chem. Soc.* 37, 1137-9 (1915).—The sample was dissolved in HNO_3 , HCl and H_2O (10 cc. each for 2 or 3 g. Fe), treated with double the theoretical amt. of pure CaCO_3 and boiled under a reflux condenser to insure the absence of CO_2 or bicarbonate. After filtration, using asbestos fiber to open the ppt., the soln. was titrated with 0.1 *N* alkali, free from CO_2 , using phenolphthalein, then adding mannitol and continuing the titration. The results obtained agree fairly well with the amts. of boric acid taken. E. B. M.

Determination of arsenic in iron, steel and ores. A. KLEINS. Duisburg-Meiderich. *Chem. Ztg.* 39, 43 (1915); cf. *C. A.* 9, 1286.—Treat 1 g. of iron or steel with 120 cc. of HNO_3 (d. 1.2) and evapor. the soln. to dryness. Heat on the hot plate until evolution of brown fumes ceases. Cool and dissolve residue in 100 cc. HCl (d. 1.19) warming gently to avoid loss of AsCl_3 . Wash soln. into a 300 cc. flask and heat on the water bath till odor of Cl is no longer noticeable. After cooling add 1 g. of KBr and 3 g. of hydrazine sulfate and connect flask by means of a long jointed glass tube to the upper end of a spiral condenser. Distil until all but a little of the liquid has passed over and the residue begins to sputter. The distillate should contain all of the AsCl_3 but no Fe or free Cl . Dil. with an equal vol. of H_2O and then sat. with H_2S . After the ppt. has settled, drive out the excess of H_2S by passing in CO_2 . Filter and wash until the washings are free from chlorides. Dissolve the ppt. on the filter with NH_4OH (d. 0.93), washing with cold H_2O and allowing the soln. and washings to run into 5 cc. of a soln. composed of 20 g. CdSO_4 , 400 cc. H_2O and 600 cc. NH_4OH (d. 0.96). The pptd. CdS is filtered off and washed with H_2O . Place filter and ppt. in 100 cc. conductivity water. Add 2.5 cc. starch soln. and 75 cc. dil. HCl (a mixt. of 850 cc. of cond. water

and 300 cc. conc. HCl) and titrate at once with standard I soln. (7.928 g. of I and 25 g. of KI per l. 1 cc. = 1 mg. S = 0.00156 g. As). Seven sets of very concordant results are given.

E. W. BOUGHTON.

Rapid method for the determination of chromium in iron and steel. H. TUSKER. *Chem. Ztg.* 39, 122(1915).—Dissolve 2 g. of the drillings in 50 cc. H_2SO_4 (1:5) in a 1 l. Erlenmeyer flask, dil. to 300 cc. with H_2O , add 8 g. of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and boil till all Mn is converted into HMnO_4 or MnO_2 (with over 0.3% Mn, the Mn generally seps. as MnO_2). If HMnO_4 forms add 5 cc. dil. HCl and boil till Cl is expelled, to decompose HMnO_4 and the excess of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ (about 5 min.), dil. to about 500 cc., cool, and titrate with FeSO_4 and KMnO_4 in usual manner. When MnO_2 seps., boil about 10 min. to decompose the excess of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and to reduce the vol. of soln., then add 5 cc. of conc. HCl and boil till the soln. becomes clear (a slight turbidity does not affect the results). The CrO_2 is not reduced by the HCl. Dil. and titrate as usual. An addition of MnSO_4 is not necessary, as the end-point is sharp, the pink color remaining some time. Excellent results are reported on a sample of steel by this method in comparison with 2 accepted methods.

F. W. SMITHER.

Determination of arsenic in the residue from the solution of iron and steel. L. BRANDT. *Z. öffent. Chem.* 21, 6-10(1915); *Chem. Zentr.* 1915, I, 459.—The total amt. of As is not in the residue; it is necessary to examine the soln. also and the gases produced by soln. with H_2SO_4 , either by pptn. with ZnS or by absorption in a HCl soln. of Br. For detn. of As is recommended pptn. with hypophosphite according to B., *C. A.* 8, 2325, and titration with 0.1 N I soln., applying a correction of 0.65 cc.

E. H.

Electrolytic analysis of alloys containing large amounts of lead, white bearing metal, type metal and brazing solders. I. COMPAGNO. Rome. *Ann. chim. applicata* 3, 164-8(1915); cf. *C. A.* 8, 642.—In white metal Pb is associated with Sn and Sb, and is sometimes accompanied by Cu, Fe, Zn, etc., as adulterants or impurities. The standard methods of analysis are objectionable, because of (1) the difficulty of complete soln. of the alloy, (2) the delicate operations attending the estn. of the PbSO_4 and recovery of small quantities of Pb passing into soln. during filtration, and (3) the prolonged action of H_2S necessary in sepg. Sn, according to Clarcke's method. C. proceeds as follows: The alloy in fragments is dissolved in a covered 150 cc. beaker with a mixt. of 4 cc. concd. HCl and 4 cc. HNO_3 (d. 1.2). After a few hrs. contact the liquid is slightly warmed to drive off nitrous vapors, and allowed to cool. The watch-glass is washed with 2-3 cc. cold H_2O , the ppt. washed by decantation 2 or 3 times with cold H_2O acidulated slightly with HCl. The decantations are made alk. with NaOH soln., and 30 cc. of Na_2S soln. (d. 1.225) added; the Pb present, and Cu, Fe, Zn, etc., are pptd. as sulfides; Sb and Sn remain dissolved as sulfo-salts. Add 0.4 g. KCN to dissolve Cu, and boil several minutes, shaking continually. After settling, filter by decantation, and decant again 2 or 3 times with warm H_2O contg. a few drops of Na_2S , collecting the filtrate in a high-form beaker of 250 cc. capacity. The ppt. of PbCl_2 remaining in the 1st beaker is dissolved in the hot with the smallest possible amt. of NaOH, the liquid dild. with 15 cc. hot H_2O , and 20 cc. Na_2S soln. (d. 1.225) added, and then 0.1 g. KCN. Boil for a few min., allow to settle, filter by decantation as before, and combine the ppts. and the filtrates. The filtrate is evapd. on the sand-bath to about 130 cc. and in 1 portion Sb and Cu are detd. together electrolytically and in the other portion Cu separately, and then Sn. The filter and the sulfides on it are brought into the original beaker and treated with 25 cc. HNO_3 (1.2), then boiled, the liquid filtered by decantation, the residue treated again as at first, and then again, but with 20 cc. conc. HNO_3 , boiling till the S collects in globules, then washing with much cold H_2O . In the filtrate of 300-350 cc., Pb is detd. electrolytically, using a

Winkler net anode, a cylindrical net cathode, c. d. = 0.3 amperes, 2-2.5 volts. It is well to keep the liquid slightly warm for about $\frac{1}{4}$ hr. before electrolysis. The results are very good. Fe, Zn, etc., are detd. by the usual methods. S. LEVY.

Penot's chlorometric method. J. CLARENS. *Ann. chim. anal.* 20, 81-4(1915); see C. A. 8, 3279. E. J. C.

Toxicological estimation of lead, especially in the urine of individuals suffering from lead poisoning. G. MEILLÈRE. *J. pharm. chim.* 10, 225-31(1915).—When Pb is to be detd. in liquids which cannot well be evapd., e. g., conc. mother liquors, or which ppt. on evapn., or in organic liquids, e. g., wine, urine, etc., quant. sepn. of Pb is effected by dissolving 0.5 g. Pb-free CuSO_4 per l. of liquid, adding 10 cc. of pure HCl per l., satg. cold with H_2S , then heating on the water bath. PbS is pptd. completely, carried down by CuS, and is free from Fe, Mn, Zn and phosphates. Filter, wash with $\text{H}_2\text{O} + \text{H}_2\text{S}$, dissolve in pure, hot HNO_3 , add H_2O , filter, evap. till dry, heat to low redness to destroy trace of organic matter, then take up the residue with 6 cc. HNO_3 , dil. with H_2O to 100 cc. and ppt. PbO_2 electrolytically at the anode. Minute details are given. S. WALDBOTT.

Determination of sulfur in organic substances. A. KRIEGER. *Chem. Ztg.* 39, 22-3(1915).—A discussion of the sources of error in the Eschka method is given. K.'s method, based on the work of Holliger and Dennstedt (cf. C. A. 3, 1380, 1625, 2281) is as follows: CoO or Pt-black are not used. A weighed sample (0.5-1 g. according to the S content) is distributed in a boat and heated in a stream of O_2 , a Cu spiral, heated to dull redness, being placed before the boat. The combustion gases pass over red hot SiO_2 which occupies about 10 cm. of the tube. The substance is burned at the lowest possible temp. The SO_2 is absorbed in a measured quantity of 0.2 N NaOH soln., the excess of alkali being titrated with HCl. The method agreed to 0.02% with control detns. by the Eschka method in which all sources of error were carefully considered, and by gravimetric detns. of the absorption soln. A disadvantage of the method is that some S remains with the ash, especially if this is high in CaO and MgO. The method is not recommended for materials of low S content, of which a large sample must be used. For such material, but not for coal and coke, oxidation with strong HNO_3 and subsequent pptn. with BaCl_2 is recommended. E. W. BOUGHTON.

Detection and differentiation of albuminous substances in plastic masses. F. STEINITZER. *Kunststoffe* 5, 73-5, 88-90(1915).—Tables have been compiled from the literature showing the principal reagents and tests for: glue and gelatin, egg and blood albumin, casein and gluten, leather meal, wood and cork meal, etc. The tests cover unhardened, hardened, and coagulated masses. Some notes on the tests are also given.

F. W. SMITHER.

Detection of cinnamic acid. D. SCHENK AND H. BURMEISTER. *Pharm. Ztg.* 60, 213-4(1915).—The method presupposes a suitable sepn. of the acid from food and drug mixts. by the use of appropriate solvents. For example, in fruit juices to which the acid may have been added as a preservative, a suitable sample (30-50 cc.) is strongly acidified with H_3PO_4 and exhausted with Et_2O . The ethereal soln. is thereupon treated with Na_2CO_3 soln., the latter then extd. twice with Et_2O to remove furfural compds. possibly present, after which operation it is transferred to a porcelain dish and very dil. KMnO_4 soln. added drop by drop until the color just ceases to be discharged. The resulting soln. is extd. with Et_2O , the ethereal layer removed to a beaker and rotated to eliminate most of the H_2O , then poured into a porcelain dish containing about 10 drops 5% phenol in Et_2O and allowed to evap. 3-5 cc. conc. H_2SO_4 are thereupon added, the typical quince-yellow color developing immediately due to the presence of BzH arising from the oxidation of cinnamic acid. W. O. E.

Castor oil plants to detect ethylene in air. E. M. HARVEY. *J. Roy. Hort. Soc.* 40, 300(1914); *Pharm. J.* 94, 357(1915).—Growing plants of *Ricinus communis* are sensitive to as little as 0.00001% of C_2H_4 in the atm. An amt. of 1:1,000,000 causes the petioles of the leaves to droop or the laminae to fold down. Similar observations have been made with sweet peas seedlings. S. WALDBOTT.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Layer dispersed systems. Geological examples. R. E. LIESEGANG. Frankfurt. *Kolloid-Z.* 16, 20-2(1915).—The bands colored with Mn and Fe in the trachyte of Hohenberg and the sandstone of Munzenberg are discussed. H. I. MATTILL.

Geochemical metal adsorption. O. NAGEL. Vienna. *Kolloid-Z.* 16, 19-20 (1915).—Pt is repeatedly found in sediments which have a high adsorptive capacity, leading to the conclusion that it was deposited there by processes of adsorption. For instance Penn. (?) clay and Brazilian itabirite contain it, probably because of adsorption by hematite. The pptn. of Au by adsorption is unquestionable in some incrustations on siderite and Brazilian limonite, and in Calif. cinnabar. The films of Ag over the skeletons of fossil fishes and in coal may be due to reduction from soln. rather than adsorption. Carnotite is found on fossils of plants and wood and K is probably held in clays by adsorption. H. I. MATTILL.

A gold-platinum-palladium lode in southern Nevada. ADOLPH KNOPF. U. S. Geol. Survey, *Bull.* 620-A, 1-18(1915).—This Au-Pt-Pd deposit at the Boss mine, Clark Co., Nevada, is not closely similar to any other deposit carrying Pt metals heretofore described. The ore shoots, occurring in dolomite, consist of fine-grained siliceous ore carrying Bi-bearing plumbojarosite, a greenish yellow mineral of smooth unctuous feel, seen under the microscope to consist of perfect hexagonal plates averaging 0.01 mm. in diameter. It carries Bi_2O_3 6.34, Au 0.79, Pt 0.05 and Pd 0.22%. The Au in this ore cannot be separated so as to be visible by panning, but is rather fine and resembles a black sand. It is not, however, alloyed with Pt; treatment of the ore with HCl alone carries much of the precious metals into soln. It is believed that the metals were formerly associated with sulfides now completely oxidized. R. C. W.

Zinc deposits of eastern Tennessee. FRANK L. NASON. West Haven, Conn. *Eng. Mining J.* 99, 734-6(1915).—Contrary to the usually accepted theory of the origin of these ores, according to which they were deposited contemporaneously with the associated Knox dolomite, and later conc. by descending waters, N. holds that they are of deep-seated vein origin. They are limited in Tenn. to the Knox, although in Virginia they occur also in adjacent shales, and are localized along fault planes and brecciated zones. The total vertical range is 4600 feet, of which 3600 is actually exposed, which suggests profound vein origin. This is further shown by the existence of numerous strike veins carrying Zn minerals in the Cambrian and Pre-Cambrian formations, which are stratigraphically beneath the Knox, along the whole length of the Appalachians. While no igneous rocks are associated with the Zn ores in the Knox, they are abundantly associated with those of the underlying formations. It is, therefore, believed that the solns. carrying the Zn have risen from deep-seated eruptives along favorable channels, and that their metal content has been pptd. by reaction with the wall-rocks, especially with the purer limestones, and it is predicted that larger deposits are likely to be found the further down exploration is carried.

E. T. W.

Quicksilver deposits of the Kuskokwim region, Alaska. ANON. *Mining Eng. World* 42, 817-8(1915).—Cinnabar associated with stibnite occurs at 2 localities in mineralized shales adjacent to granitic dikes. E. T. W.

The origin of the inclusions in dikes. SIDNEY POWERS. *J. Geol.* 23, 1-11, 166-83 (1915).—Inclusions in dikes are rare; the majority have been shattered from the walls either in the formation of the fissure or in the injection of the dike magma. In a few instances the inclusions are pebbles derived from a conglomerate. The direction and amt. of movement of the inclusions does not depend as much upon the sp. gr. of the magma relative to that of the inclusions as upon the mechanics of intrusion and the circulation in the dike magma before its consolidation. The inclusions are in general rounded when coming from depths and angular when near the place of origin. The material worn from fragments during their rounding and the cement which is dissolved from conglomerates appear in the dike as xenocrysts. The question of fragmentation of the constituent minerals from differential expansion and the importance of the inversion point of quartz are of bearing in quartzose inclusions only where these have been heated to 575°.

W. F. HUNT.

Geology of the Diamond Hill-Cumberland District in Rhode Island-Massachusetts. CHARLES H. WARREN AND SIDNEY POWERS. *Bull. Geol. Soc. Am.* 25, 435-76(1914).—The area described is of interest because of the occurrence of the rare ultrabasic rock cumberlandite, of riebeckite granite and associated porphyries, and of a quartz deposit known as Diamond Hill. The greater part of the cumberlandite is highly altered. The original rock consists of a fine-grained groundmass of olivine (40%) crystallographically intergrown with 18-20% of magnetite and ilmenite. Phenocrysts of labradorite, singly and in clusters, constitute 10%. In the ore matrix is about 3% of dark green spinel crystals. Estimate of the mineral comp. of a section of the riebeckite granite gave 48.9% microcline-micropertthite, 33.3 quartz, 8.5 riebeckite, 7 aegirite, and 2.3 accessories (astrophyllite, fluorite, zircon, and ilmenite). The Diamond Hill quartz deposits cover about $\frac{1}{4}$ of a sq. mi. and of this $\frac{1}{4}$ is either quartz, chiefly of the milk-white variety, or highly silicified felsite. In the veins the crystals grow perpendicular to the walls, giving rise to comb structures. In the quartz casts of square, rectangular, or tabular outlines identified as casts of barite crystals are of frequent occurrence. The quartz represents the last phase of igneous activity, replacing the felsite where brecciation was greatest.

W. F. HUNT.

Origin of oolites and the oolitic texture in rocks. THOMAS C. BROWN. *Bull. Geol. Soc. Am.* 25, 745-80(1914).—Recent oolites now forming in Great Salt Lake, Pyramid Lake, various hot springs, and in the open ocean are composed of aragonite with nuclei of sand grains or other foreign material. Direct chem. pptn. has been caused by the reaction of Na_2CO_3 on the CaSO_4 held in soln. The older oolitic beds of Pa. were originally composed of aragonite. Where not affected by waters bearing other minerals in solution they changed to the more stable form, calcite. Sometimes the resulting cryst. calcite shows twinned lamellae. When the circulating waters contained Mg salts the oolites became altered to dolomite and lost their concentric and fibrous structures. In the case of siliceous waters the oolites were replaced by SiO_2 . The original nucleus was secondarily enlarged, deposition taking place in optical continuity. With the SiO_2 is often deposited Fe_2O_3 intimately mixed with the fibrous chalcedony. In the Clinton formation the original aragonite oolites were changed by ferruginous solns. into oolites of Fe_2O_3 and SiO_2 , with the former in excess. W. F. H.

Ground water for irrigation in the Sacramento Valley, California. K. BRYAN. U. S. Geol. Survey, *Water-Supply Paper* 375-A, 1-49(1915).—B. gives diagrams showing origin and movement of the ground water, its amt. and the fluctuations of the water table, and concludes that alkali would form even more extensively if it were not for

the winter rains which leach out the salts formed by evapn. during the summer, and also for the fact that sediments are deposited at the very points where there is the greatest tendency towards the formation of alkali, thus burying it. R. C. WELLS.

Isostasy and radioactivity. GEORGE F. BECKER. *Bull. Geol. Soc. Am.* 26, 171-204 (1915); see C. A. 9, 752. W. F. HUNT.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

The formation and decomposition of sulfates during roasting. II. B. DUDLEY, JR. *Met. Chem. Eng.* 13, 303-8(1915); cf. C. A. 9, 1293.—A study of the effect of reaction velocity. Expts. are reported on the velocity of decompn. of NiSO_4 in a current of air at 710° and 770° , of CdSO_4 in dry air current at 960° , $\text{Al}_2(\text{SO}_4)_3$ in a current of dry air at 735° and 800° , first alone and then with Fe_2O_3 , $\text{Al}_2(\text{SO}_4)_3$ in dry air at 800° with Pt-asbestos. The rate of dissociation of the sulfate was accelerated by the addition of Fe_2O_3 , the av. ratio of SO_3 to SO_2 being 0.71 vols. of the former to 1 of the latter. The amt. of Pt-asbestos required to produce a given effect was much less than of Fe_2O_3 . Since at atm. pressure and 800° SO_3 alone will dissociate until its ratio to SO_2 is only 0.433 to 1, the ratio 11:1 obtained when $\text{Al}_2(\text{SO}_4)_3$ was heated alone indicates conditions far removed from equil., while the ratios 0.71 and 0.73 to 1, obtained in the presence of catalysts, indicate conditions near to the equil. From exptl. and other data D. traces what may be called the "life history" of a sulfate or of a number of sulfates, from which it is concluded that there is no definite order in which the metal sulfates make their appearance in the roasting furnace. Sulfates may begin to form in roasting as soon as corresponding oxides are produced, provided SO_2 and O are present to form the necessary SO_3 —the condition being that the dissociation pressure of the sulfate is less than the existing partial pressure of SO_3 . This condition is most likely to occur in the deeper portions of the ore bed. The reverse of this condition will cause dissociation of the sulfate, and conditions tending to produce dissociation are to be expected at the upper surface of the ore bed. As the ore is generally stirred to a greater or less extent, at no time can a single oxide monopolize all of the SO_3 in any part of the furnace, hence many sulfates may be formed and decomposed at the same time. (This includes no consideration of the rate of formation and decomp. of the various sulfates which has been previously discussed.) As the ore is advanced in the furnace and its temp. is increased the dissociation pressures of the various sulfates that have been formed increase, and their tendency toward dissociation increases accordingly. Increasing temp. tends to reduce the partial pressure of SO_3 maintained within the interstices of the ore bed by shifting the equil. of the SO_2 , O, and SO_3 system. This SO_3 in these spaces may be reduced below the dissociation pressures of many of the sulfates, and at elevated temps. even in the deeper portions of the ore-bed sulfates may undergo decompn. at a fair rate. At this stage the presence of the Fe_2O_3 and other catalysts aids the dissociation of SO_3 , thus accelerating the dissociation of the sulfates. Therefore, at high temps. Fe_2O_3 aids in the dissociation of the same sulfates that are formed by its aid at lower temps. Since the basic sulfates have in general lower dissociation pressures than their corresponding normal compds., the former will persist at higher temps. and for a greater time than the latter. For the complete elimination

of S it may in some cases be necessary to produce reactions between various gang constituents and the remaining sulfates or basic sulfates. By this means the SO_2 is liberated and such compds. as silicates and ferrites are formed, with or without complete fusion of the roasted material. Tables and curves are given. F. W. S.

Treatment of copper mats in the basic converter at the works of Karabach (Ural, Kishtim district). K. D. KOLASNIKOW. *Rev. métal.* 11, 519-43(1914); *J. Soc. Chem. Ind.* 33, 596.—Mats contg. Cu 7-49, Fe 26-60, S 23-5%, are "blown" in 2 stages. The white mat, produced in the first stage, generally approximates to Cu_2S in compn. The coarse Cu from the second stage contains Cu 98-9%, together with about 97% of the Au and 40% of the Ag present in the white mat. The slag (contg. Cu 1-2%) varies in compn. from $3\text{FeO} \cdot \text{SiO}_2$, to $2\text{FeO} \cdot \text{SiO}_2$ according to the compn. of the mat bath and the temp. The complete data relating to the treatment of about 100 kg. of mat contg. Cu 33.5% are given and discussed in detail.

E. J. C.

A case of copper hydrometallurgy. Inexpensive and efficient treatment of smelter flue dust and carbonate ore. G. C. WESTBY. *Mel. Chem. Eng.* 13, 295-7(1915).—The plant described cost about \$1200 and the estd. cost of production per lb. of Cu resulting from the hydraulic sluicing of flue dust amounts to 7.5 cents. From an exptl. batch in which 248 tons of flue dust and 250 tons carbonate ore containing 19,073 lbs. of Cu were used 18,073 lbs. of Cu were recovered, the % recovery amounting to 94.4%. The treatment described proved a successful solution of a minor smelter problem.

C. A. NOWAK.

An attempt at tin concentration. JESSE SIMMONS. *Eng. Mining J.* 99, 816-7 (1915).—The ore contains cassiterite occurring in grains and crystals varying from the size of a pinhead to several times larger. The gang is quartz and mica. The process, as illustrated by a flow sheet, saves most of the mica contents and will also give clean quartz sand as another by-product. The former sells as scrap mica at from \$12 to \$15 per ton. The latter, containing no Fe or other coloring matter, should find ready sale to concrete workers.

L. A. TOUZALIN.

The continuous production of liquid metallic zinc in the blast furnace. A. RZE-HULKA. *Chem. Ztg.* 38, 895-7, 937-9(1914); *Oesterr. Z. Berg. Hüttenw.* 62, 573-7 (1914).—A discussion of the metallurgy of Zn, especially the economic phase. From theoretical deductions and calcs. it is concluded that it is impossible in the present state of science and technics rationally to reduce Zn ores to liquid Zn in the blast furnace on a practical scale.

F. W. SMITHER.

Cyaniding at the Bullfinch Proprietary, Western Australia. A. L. HAY AND R. B. WILLIAMSON. *J. West. Australia Chamber of Mines*, Dec., 1914 and Jan., 1915; *Mel. Chem. Eng.* 13, 331-2(1915).—The ore is a mixt. of both oxidized and sulfide material in about equal proportions. The metallic minerals are Au, galena, pyrite, marcasite and pyrrhotite. The galena is Ag-bearing and some native Ag occurs in the oxidized ore. A flow sheet shows the operations to be as follows: breaking in a Symons gyratory; crushing by 1200-lb. stamps, hydraulic classification with tube-milling of the over-size; pan-amalgamation of the tube-mill discharge; thickening and agitation of the classifier under-size; filtration by vacuum in a Ridgway filter; and pptn. in Zn boxes. Other details including costs are given.

L. A. TOUZALIN.

Recent Rand metallurgical practice. M. T. MURRAY. *Eng. Mining J.* 99, 771-3 (1915).—A review of recent changes. Better extn. and lower costs have been obtained by the application of new methods and machinery.

E. J. C.

Some appliances for metallographic research. W. ROSENHAIN. *Natl. Phys. Lab., England. J. Inst. Metals* 13, 26 pp.(1915) (advance copy).—A levelling device

for metallographic specimens consists of a telescope objective, in the axis of which is set a 45° plane glass reflector. Light is admitted through a hole in a side tube, this hole being at the same distance from the reflector as the reflector is from the principal focus. This light is reflected downward by the reflector onto a piece of plane plate glass with accurately parallel surfaces, the lower one of which is silvered. With this surface at right angles to the axis of the telescope the image of the hole in the side tube falls on the cross wires. If a polished metallographic specimen, mounted on a glass slide by soft wax, be placed on the plate glass, its surface reflects the image of the hole, and when this image falls on the cross hairs, the surface is parallel with the bottom of its mounts. The ordinary specimen may be levelled in a minute by this means so as to avoid refocussing in the exam. of an area 0.5 in. square under 400 diam. magnification. The device was constructed to R.'s design by R. and J. Beck. A furnace for taking heating and cooling curves at any desired rate of heating may be constructed by winding the upper 6 in. of a 24 in. fireclay tube with nichrome wire and lagging with sectional magnesia covering. With the hottest zone at 1000° , conduction and radiation give any lower temp. desired, down to 200° , at some lower portion of the furnace. Ten amps. at 100 v. are used, supplied by a large storage battery. The desired rate of heating or cooling is obtained by raising or lowering a Pt blank at such a rate (by elec. motor or by gravity controlled by a hydraulic cylinder with relief valve) as will give that rate. Differential curves are readily taken between blank and sample. A plotting chronograph capable of plotting inverse rate curves with a high degree of accuracy has been constructed on R.'s plans by the Cambridge Scientific Instrument Co., and is described in detail.

H. W. GILLET.

The influence of nitrogen upon the mechanical properties of iron. N. P. CHIVYEVSKII. *Rev. soc. russe metal* 1, 135-9(1913); *Rev. métal.* 11, II, 618-20.—Using a sample of Martin steel (containing 0.14% C, 0.18% Si, 0.45% Mn, 0.07% S and 0.03% P) in the form of wire of 0.63 mm. diam., a coil was made 40 mm. in diam. and placed in the tube of an Heraeus furnace. During periods varying from 1 min. to $\frac{1}{2}$ hr., NH_3 gas was passed over the metal heated to 900° , followed by N at 1100° for 4 hrs. After this treatment, the metal had a bright silvery appearance. The content of N was varied in different samples from 0.00393% to 0.222%. Mechanical tests made upon the treated steel show that N has a considerable and detrimental effect. Since acid Bessemer steel contains about 5 times as much N as Martin steel, C. suggests that this fact may in part account for the relative inferiority of the former.

L. T. F.

Iron and nitrogen. N. P. CHIVYEVSKII. *Rev. soc. russe metal* 1, 127-35(1913); *Rev. métal.* 11, II, 617-8.—Analyses show that Bessemer steel contains from 0.014 to 0.015% N and Martin steel from 0.003 to 0.004% N. Pure Fe does not combine directly with dry N at any temp., but in the presence of NH_3 gas, combination takes place readily, the optimum temp. being 450° . The effect of N upon Fe containing C, Mn, and Si was studied. A Swedish Fe containing 3.96% C could not be made to combine with N at any temp., showing that C plays no part in the absorption of N. With Mn and Mn-Fe alloys, combination occurs, the optimum temp. being 700° with NH_3 and 1000° with pure N. The compds. formed are Mn_3N_2 and MnN . That this may in part account for the presence of N in steel was shown by the fact that a steel containing Mn heated in a furnace showed the presence of nitrides on its surface. C. finds that Si, in the form of its nitrides Si_3N_4 , Si_2N_4 , and SiN , is sol. in Fe and that this, perhaps, more than Mn is the source of N in Fe. Al forms a nitride, AlN , which does not dissociate at 1700° . Al, added to liquid steel, combines with any N present to form AlN which remains in the Fe in the form of a solid soln.

L. T. FAIRHALL.

Experiments upon fragility. CH. DE FREMINVILLE. *Rev. métal.* 11, I, 971-1056 (1914).—A very complete study of the question of fragility in which a great number

of expts. with widely varying materials has been carried out. The attempt has been made to cover the field from a qual. viewpoint only.

L. T. FAIRHALL.

Calorizing metals. WILLIAM E. RUDER. *Trans. Am. Electrochem. Soc.* 27(1915) (advance copy); cf. Allison and Hawkins, *C. A.* 8, 3773.—Calorizing consists in producing a rich Al alloy upon the surface of the metal to be protected. The process is particularly applicable to metal containers and parts which are to withstand oxidation at temps. above red heat. The metal pieces to be treated are packed in a mixture of powdered Al_2O_3 , NH_4Cl (1%) and 5 to 50% of Al metal. For Cu and brass parts the mixture is kept low in Al and the temp. of firing held at about 700–800°. For steel and Fe, richer Al mixtures are used and fired at 900–950°. The firing is carried out in a gas-tight receptacle in a reducing or inert gas atm. (to prevent burning of Al). Usually 2–3 hr. firing is sufficient. R. records tests made on calorized *vs.* uncalorized Fe tubes. The tubes were heated in an open flame at 900° for 8 hr. At the end of this time the calorized tubes were practically unchanged whereas the uncalorized tubes were scaled and cracked about half way through. The Al alloy coating is about 0.025–0.010 mm. thick. When the piece is kept at a high temp., as in service, this narrow band of alloy gradually widens as the Al diffuses into the Fe. This diffusion which proceeds very slowly at 800–900° becomes very rapid at higher temps. necessitating a heavy coat of rich Al alloy for pieces to be used above 1000°. For service above this temp. calorized wrought Fe and steel show better life than calorized cast Fe. The process is finding considerable application in furnace parts, pyrometer tubes, annealing boxes, combustion tubes, etc. Cu and Ni are also calorized and thus rendered more resistant to oxidation at high temp. Many photos and curves are shown. Calorized Fe is more resistant towards acid than the bare metal.

Etching reagents and their application. O. F. HUDSON. Birmingham Univ. *J. Inst. Metals* 13, 22 pp. (1915) (advance copy).—The various etching agents best fitted for use on Cu, brass, bronze, Al bronze, German silver, Ni-Cu alloys, Au, Pt, Al, Pb, Sn, Zn, and the alloys rich in the last 6, as well as for Fe and steel, are discussed, the comp. and strength of the reagents being fully described, and many comments on the technic of etching being given.

H. W. GILBERT.

Ingot mold compound for the casting of brass cartridges. M. F. CERON. *Res. metal.* 11, I, 780–4(1914).—To overcome the tendency which brass has on solidifying of forming pockets that retain gaseous or solid impurities, the principle of progressive cooling from the lower part of the mold to the upper is utilized. The mold is constructed of Cu, Fe and a refractory earth, Cu forming the lower layer. Cu conducts heat so much better than Fe that the mass slowly solidifies from the bottom giving a casting free from pockets of impurities.

L. T. FAIRHALL.

The mechanical anisotropy of coarse-grained metals and alloys and the Brinell test. A. PORTEVIN. *Compt. rend.* 160, 344–6(1915).—Metals and alloys are made up of individual grains or crystals and in each crystal the resistance to mechanical strain is a function of the direction in which the force is applied. With fine-grained metals or alloys the crystals are arranged so irregularly that such materials are practically isotropic. The expts. described show that with coarse-grained metals the results obtained in the Brinell test are dependent upon the direction in which the force is applied. Very consistent measurements can be made when only a single grain is affected but the values are different in different directions. When the test is applied so that different grains are affected and in different directions, then the results are likely to vary very considerably.

W. T. H.

The elasticity of flexure of cast iron. A. ONO. *Mem. Coll. Eng. Kyushu Imp. Univ.* 1, 111–64(1915).—Tensile strength, compression and bending tests were applied

to cast Fe rods containing 3.36 C, 2.06 Si, 0.99 Mn, 0.18 P, 0.05 S and 0.24% Cu. For the details concerning the numerous tests and the mathematical discussion of the results, the original must be consulted.

W. T. H.

The quantitative effect of rapid cooling upon the constitution of binary alloys. III.
G. H. GULLIVER. *J. Inst. Metals* 13, 31 pp. (1915) (advance copy).—A mathematical discussion of the deviation from equil. conditions of rapidly cooled alloys, and the application of the theory to some specific cases. Thus, at a normal rate of cooling, the ordinary alloy with 92% Al and 8% Cu contains about 10% eutectic, although at equil. it is homogeneous without eutectic. To get 10% eutectic in an alloy under equil. conditions requires about 12% Cu. The application of the theory to Al-Sn alloys indicates that the satn. point of Sn in Al solid soln. is less than 10% Sn, although 20% is usually assumed. Curves are given showing the application of the theory to parts of the Pb-Sn, Cu-Sn, Cu-Zn, Cu-Ni and Cu-Al diagrams.

H. W. GILLET.

The permanent deformation of copper produced by compression and by traction.
M. BRILLOUIN. *Ann. phys.* 2, 489-96 (1914).—The permanent deformation produced in well annealed, electrolytic Cu has been studied under different conditions by Vielle (1892) and by Bouasse (1899). In this paper the results obtained by these 2 investigators have been compared and reconciled with one another.

W. T. H.

Some experiments upon copper-aluminium alloys.

J. H. ANDREW. *Engineering* 99, 446-9 (1915); *J. Inst. Metals* 13, 14 pp (1915) (advance copy).—The equil. diagrams of Carpenter and Edwards (*C. A.* 1, 1534) and of Curry (*C. A.* 1, 2995) differ from one another in several important details, especially with regard to alloys containing between 80 and 100% Cu. Alloys containing 10-20% Al were prepared and studied by means of cooling curves. From the results obtained the diagram has been modified slightly (see fig.).

L. F. HAMILTON.

The constitution of the alloys of copper with tin.

JOHN L. HAUGHTON. *Engineering* 99, 419-22 (1915).—On account of serious discrepancies in the Cu-Sn equil. diagram as drawn by previous investigators, it is proposed to reconstruct the entire diagram and to

publish the results from time to time as soon as sufficient data has accumulated. This paper is concerned with the range and position of the constituent ϵ which is not shown at all in the diagram of Giolitti and Tavanti (*C. A.* 2, 3054), is shown existing along a line sloping from 61.1-65% Sn by Heycock and Neville (1903), as a narrow strip containing 59.5-60.5% Sn at its temp. of formation and 59.5-62% Sn at 0° by Shepherd and Blough (*C. A.* 1, 36), while Hoyt (*C. A.* 8, 484, 3413) shows it by means of a lenticular-shaped area forming at 49% Sn and spreading out to a range from 47 to 50% Sn at 300°. Hoyt gives 500° as the temp. at which it first appears but by others 400° is usually assumed. The study of heating and cooling curves and of photomicrographs now shows that the comp. of ϵ varies slightly with the temp. at which it seps. out. Pure ϵ , which is formed by the reaction $\eta + \text{Sn} = \epsilon$ contains 59% Sn at 400° and between 59.8 and 61% Sn at 250°. The temp. at which ϵ is first formed is indicated at 401° by cooling curves and at 415° by heating curves.

W. T. HALL.

Action of lead, copper, tin, nickel, zinc and aluminium on water. W. P. JORISSEN. *Leiden. Chem. News* 111, 56-7, 91-2, 102 (1915).—The principal investigations on

Per Cent Al.

the corrosion of these metals are summarized and discussed chiefly from the standpoint of electrolytic corrosion and passivity. The difficulty in predicting what will happen when one of these metals is brought into contact with a special kind of drinking H_2O is pointed out as well as the need of further expts. to show the order of the metals, with respect to their potentials, when placed in different salt solns. and in the various kinds of H_2O found in nature. W. H. S.

The properties of some nickel-aluminium and copper-nickel-aluminium alloys. A. A. READ AND R. H. GREAVES. Univ. College, Cardiff. *J. Inst. Metals* 13, 52 pp. (1915) (advance copy).—The physical properties of some of the light alloys of Al with Ni and with Ni and Cu up to about 12% of Cu and Ni were studied. An alloy of 80 Al, 20 Ni was made up by adding shot Ni to molten Al at about 850° (estd.), too low temps. not giving rapid enough soln. of the Ni and too high ones probably causing the formation of Al_3Ni . Tensile tests were made on some of these as cast, also on hot rolled, cold drawn and annealed rods. Increase in Ni in the binary alloys (the range covered by the samples was 0 to 5.5% Ni) increases tensile strength and decreases elongation. The alloy with 5.5% Ni has 19000 lbs. per sq. in. tensile strength and 9% elongation on the chill casting 1 in. diam., turned down to 0.564 in. diam. The strongest chill cast alloy contained 2% Cu and 5.25% Ni and gave 25500 lbs. per sq. in. and 6%. In cold rolling, the alloys whose comps. lie in the corner of the triangular diagram back of a line drawn from 4.5% Ni to 3.5% Cu were sound; beyond it they cracked. In hot forging the division line of soundness runs from 7.5% Ni to 5.5% Cu, in wire drawing from 4% Ni to 6% Cu. The yield points by several methods, and the approximate true elastic limits were compared. In general the alloys were studied by taking const. Cu content (as 1%, 2%, 4%) and adding various amts. of Ni, and *vice versa*. All castings were poured as cold as possible, but no actual measurements of pouring temp. were made. Qual. expts. show that castings poured hot are weaker than those poured cold. Alternating stress tests on an Arnold machine were made on hot and cold rolled and on annealed rods, 2% Ni giving the best results on the annealed samples, 2% Cu + 1 to 2% Ni, on the others. Hardness was detd. by Shore and Brinell methods, and increases with increases in Cu + Ni. The sp. gr. is a linear function of total Cu + Ni present, and is slightly lower than the calc. density. In the range studied, the m. ps. drop as the Cu + Ni increases, the alloy with 5.5% Ni melting at 637° and that with 4.1% Cu + 4.3% Ni at 619°. Elec. cond. of the 1.9% Ni alloy (pure Al = 100) is 93.2, of the 4.3% Ni 86.5, of the 4.1% Cu + 2.2% Ni 77.8. Corrosion tests were made in fresh and sea water, but the results are not very conclusive. All the alloys corroded more than pure Al. Six photomicrographs are given. Ni forms a eutectic with Al just as Cu does, and substitution of an equal wt. of Ni for Cu makes no marked difference in the microstructure, *i. e.*, 4% Ni + 4% Cu contains about the same amt. of ternary eutectic that 8% Cu does of binary. In general, the properties, *d.*, tensile strength, etc., of an Al-Cu are not materially altered by substitution of Ni for Cu, since Cu and Ni have almost identical ds. and similar atomic vols. On account of the fact that the cost of Ni is higher than that of Cu, the greater difficulty of making an Al-Ni than an Al-Cu alloy, and the greater tendency of the Ni alloy toward pipping, there is apparently nothing to be gained in substituting Ni for Cu in the light Al alloys.

H. W. GILLET.

Alloys of mercury with thallium. P. PAVLOVICH. *J. Russ. Phys. Chem. Soc.* 47, 29-46(1915).—An exam. of the diagrams of fusion, elec. cond., hardness and potential of alloys of Hg with Tl resulted in the following conclusions: The statement of Kurnakov and Pushin (*J. Russ. Phys. Chem. Soc.* 38, 1166) concerning the existence of an irrational compd. of these metals is correct. Such an irrational compd. is indicated on the m. p. curve at 29-30 (at.) % Tl, on the cond. curve at 26-28% Tl, and on the

e. m. f. curve at 27-28.4% Tl (*loc. cit.*, 899). The existence of such an irrational compd. may be due to the dissociation of Hg_2Tl , forming with its components solid solns. within the range of 21-31 at. % of Tl. The presence of Hg_2Tl in the α phase of the system Hg-Tl is corroborated by the fact that in the range of this compd. the temp. coeff. of resistance is nearly the same as that of the pure metals (Stepanov's rule, elec. cond. of metallic alloys). In the range of 86-100% of Tl there is an enormous increase of hardness.

H. M. GORDIN.

Alloys having remarkable properties at very high or very low temperatures. L. GUILLET. *Rev. metal.* 11, I, 969-70(1914).—Alloys or metals having a high temp. resistance have a breaking strength and an elastic limit of 5-8 kg. per sq. mm. at about 750-800°. A Ni-steel alloy hardened with Cr and W is described which has a breaking strength of 24 kg. at 800°. Another alloy shows a resistance of 50 kg. at -195°, while soft steel gives a resistance of no more than 3 kg. at this temp. Tammann cites two alloys of Cr-Co, one of which (Cr 25%, Co 75%) has a resistance of 44.9 kg. at 720°; the other (Cr 30%, Co 70%) has a resistance of 65.1 kg. at the same temp.

MeCHCl-(CH₂)₂COEt (A) in EtOH, when heated under reflux for 2 hrs. with 2 mols. HONH₂·HCl (which had been just neutralized with K₂CO₃), gave rise to the compound C₇H₁₁ON₂ (B), b₁₃ 118-9°, n_D²⁰ 1.49394, which is either the orthoxazine, N:CEt.CH₂.CH₂.CHMe.O or the isoxazine, HN.CEt:CH.CH₂.CHMe.O, the latter

formula being in somewhat better accord with the experimentally detd. mol. refraction and dispersion. The *picrolonate* of (B), brilliant, brownish red prisms, m. 148°, on a Hg bath. By adding 13.5 g. (A) to a satd. aq. soln. of 7.8 g. HONH₂·HCl, incompletely neutralized by the addition of 6.5 g. K₂CO₃, shaking the mixt. at intervals during 8 days and finally extg. with Et₂O, W. obtained the *oxime* of (A), oil, which when heated in abs. EtOH with C₄H₅N on a H₂O bath for 6 hrs., gave rise to (B). The compound, C₄H₁₁ON (CH₂.CH₂.CH₂.O.N:CEt or CH₂.CH₂.O.NH.CEt:CH), b₁₃

130-1°, was prepd. from CH₂Cl(CH₂)₂COEt (C) by a very similar method. H₂NNH₂·H₂O reacting with (A) gave rise to 6-methyl-3-ethyltetrahydropyridazine, CH₂.CH₂.CEt:N.NH.CHMe, b₁₁ 77.5-8.0°; *hydrochloride*, hygroscopic powder (from

acetone), m. 117°; *benzoyl derivative*, faintly colored prisms, m. 56°. 3-Ethyltetrahydropyridazine, b₁₁ 77°, was prepd. by a similar method. Its hydrochloride and chloroplatinate are very unstable; its *benzoyl derivative*, b_{12.6} 202°; *urea derivative*, H₂NCON.CH₂.CH₂.CH₂.CEt:N.NH₂·H₂O, efflorescent prisms, m. 81°, was formed when

(C) in HCl was treated with KNCO or when the semicarbazone of (C) in abs. EtOH was treated with an equimol. amt. of C₄H₅N for 6 hrs. under reflux. The γ -Cl ketones, when treated with PhNHNH₂ in EtOH gave rise to *N*-phenyltetrahydropyridazines. 1-Phenyl-3-ethyl-6-methyltetrahydropyridazine (from A), CH₂.CEt:N.NPh.CHMe.CH₂

or CH₂.CH:CEt.NH.NPh.CHMe, b₁₁ 205-7°; its corresponding *phenylcarbamyl derivative*, leaflets, m. 152-3°. 1-Phenyl-3-ethyltetrahydropyridazine (from C), microcrystals, m. 77-8°; *phenylcarbamyl derivative*, needles, m. 158°. LOUIS E. WISE.

Catalytic reduction of indigo and vat dyes. ANDRÉ BROCHET. *Compt. rend.* 160, 306-8(1915).—A method is given for the prepn. of concd. solns. of indigo white, free from inorg. salts and other impurities. 10 g. of dry indigo suspended in 250 g. H₂O containing a given small amt. of NaOH and 5 g. active Ni was shaken in a H atm. at 70° for about 40 min., 851 cc. or 0.076 g. of H (dry) being required for complete reduction. The filtered solution which contains the indigo white may be further concd. *in vacuo*. The Schützenberger process now in general use requires 7 g. NaHSO₃ to effect a similar reduction and yields a contaminated product. The Ni retains its catalytic properties for a long time. By similar methods the leuco bases of other vat dyes (derivs. of indigo and thioindigo) may be readily prepd. LOUIS E. WISE.

Reaction of homopiperonyl and homoveratryl alcohols. GERTRUDE M. ROBINSON. Sidney. *J. Chem. Soc.* 107, 267-76(1915).—2,3,6,7-Dimethylenetetraoxy-9,10-dihydroanthracene (A), obtained by Ewins (C. A. 4, 195) by the action of PCl₅ on homopiperonyl alc. (B), was more readily synthesized by gradually adding 2 g. H₂SO₄ in 20 cc. glacial AcOH to 20 g. (B) in 60 cc. hot AcOH. When treated with

a HNO_3 -AcOH mixt., (A) formed a NO_2 deriv. m. 217° . 2,3,6,7-Tetramethoxy-9,10-

dihydroanthracene (C), $(\text{MeO})_2\text{C}_6\text{H}_3$  $\text{C}_6\text{H}_3(\text{OMe})_2$, needles, m. 227° , was prepd.

by the action of 35% HCO_2H on o -(MeO) $_2\text{C}_6\text{H}_4$ in H_2SO_4 , or (less readily) by the action of glacial AcOH containing a few drops of H_2SO_4 upon homoveratryl alc. (C) dissolves in H_2SO_4 , forming a magenta-colored soln., which on warming changes to a violet. On boiling with HI, (C) formed a dark product, which, after washing with NaHSO_3 and distg. over Zn dust in a stream of H_2 , was converted into 9,10-dihydroanthracene, m. 106° (cf. Lieberman and Topf, *Ann.* 212, 5). When heated with HNO_3 , (C) was oxidized to a mixt. of 2,3,4,5-(MeO) $_2(\text{O}_2\text{N})_2\text{C}_6\text{H}_3$, m. 132° , and 6-nitroveratric acid, m. $187-8^\circ$. (C), when mixed with an excess of PbO and distd., was converted into 2,3,6,7-tetramethoxyanthracene (D), prisms from AcOEt with 1 mol. of solvent, m. 141° , resolidifying and rem. about 169° . When recrystd. from EtOH (D) m. 173° . Solns. of (D) exhibit a brilliant blue fluorescence. In an attempt to obtain (D), R. treated hydroveratroin with SnCl_4 , but the resultant product was found to be tetramethoxydeoxybenzoin (cf. *Ann.* 329, 48). By condensing $(\text{CHO})_2$ and veratrole, in the presence of H_2SO_4 , (D) was not formed, but *s*-tetraveratrylethane, $\{[3,4-(\text{MeO})_2\text{C}_6\text{H}_3]_2\text{CH}_2\}_2$, needles from AcOEt, m. 148° . The synthesis of 3,4,3',4'-tetramethoxydiphenylmethane, $[(\text{MeO})_2\text{C}_6\text{H}_3]_2\text{CH}_2$ (E), leaflets from light petroleum, m. 70° , b_{24} 257° , may be summarized as follows:

$\rightarrow$ (E). On treatment with H_2SO_4 and HCHO, followed by the addition of H_2O , (E) yielded (C). The 6,6'-dinitro derivative of (E), pale yellow needles, m. 183° , was obtained either by treating (C) with a HNO_3 -AcOH mixt., or by the direct nitration of (E) in glacial AcOH. The di- NO_2 deriv., when boiled with 15 parts HNO_3 , formed the 2,6,2',6'-tetranitro derivative of (E), nearly colorless, rhombic prisms, m. 210° . Isosafrole undergoes polymerization when treated with H_2SO_4 -AcOH mixt., forming *trans*(?)-di-isosafrole, m. 145° (cf. Angeli and Mola, *Gazz. chim. ital.* 24, 127) and an oil (F), b_{30} 225° . The isomeride, m. 92° , described by Mayer (cf. *C. A.* 8, 3022) was not isolated. Attempted nitration of (F) resulted in an oxidation with the production of EtCO_2H , but no well defined NO_2 derivs. of (F) were obtained.

LOUIS E. WISE.

Volatile oil from tubers of *Kaempferia ethelae*. ERNEST GOULDING AND OSWALD D. ROBERTS. *J. Chem. Soc.* 107, 314-9(1915).—By steam distn. of 31.8 kg. of the tubers and rootlets of *Kaempferia ethelae* (grown in the Transvaal), G. and R. obtained 440 g. of a light oil (A) and 33 g. of a heavy oil (B). (A) had the following const.: d_{15}^{15} 0.9437; α_D^{25} $19^\circ 47'$; acid no. 2.3; ester no. 5.0; ester value after acetylation 47.6. The mixt. of (A) and (B) had approx. the following compn.: terpenes (including dipentene, identified by means of the tetrabromide, m. $124-5^\circ$, and very probably pinene) 21.8%; cineol, m. 112° , 17.2%; acids (chiefly or entirely AcOH) 0.1%; phenols, 0.5%; alcs. (including linalool, identified by means of its conversion product, citrylidene-cyanoacetic acid, m. $120-1^\circ$), 11.2%; esters (chiefly *o*- $\text{MeHNC}_6\text{H}_4\text{CO}_2\text{Me}$, identified by means of $\text{MeHNC}_6\text{H}_4\text{CO}_2\text{H}$, m. 179°), 1.3%; a new ketone, $\text{C}_{24}\text{H}_{28}\text{O}_4$ (C), diamond-shaped crystals, m. 102° , $[\alpha]_D^{25}$, $198^\circ 20'$, 13%; and a residue consisting largely of sesquiterpenes, 34.9%. (C) was isolated from a fraction of the oil b_{30} above 135° . It is practically odorless, but its EtOH soln. possesses a characteristic odor of crushed ivy leaves. It is highly unsatd., adds Br readily, but does not unite with NaHSO_3 or Na_2SO_3 , and is not attacked by alk. KMnO_4 . CrO_3 , however, decomps. (C) completely.

When treated with HONH_2HCl and a slight excess of aq. NaOH , (C) forms a *hydroxylamine oxime*, microcrystals, m. 184° , which when shaken with very dil. HCl was converted into the free *oxime*, cryst. tufts, m. 166° . No acetate of (C) could be obtained, but a *benzoate*, cream-colored powder, m. above 260° (decompn.), was prepd. The action of 0.5 N alc. KOH on (C) gave rise to an unidentified compd., m. about 200° (decompn.).

LOUIS E. WISE.

Formation of coumarin derivatives and the preparation of stable coumarinic acids.

LOUIS A. JORDAN AND JOCELYN F. THORPE. Imp. Coll., So. Kensington. *J. Chem. Soc.* 107, 387-406(1915).—The compd. m. 134° (cf. C. A. 7, 336) previously obtained in small amt. as a by-product in the synthesis of Et β -methylgluconate from Et isodehydroacetate, was prepd. in larger quantity and has been shown to be *ethyl 3-acetyl-4,5,7-trimethylcoumarin-6,8-carboxylate* (I), needles, m. 135° , b₁₅ 253° . When dissolved in warm, concd. aq. KOH , (I) is converted into α -acetyl-3,5-dicarbethoxy- β ,4,6-

(I)

(II)

(III)

trimethylcoumarinic acid (II), small plates from EtOH , m. 146° , giving a purple color with FeCl_3 and passing back into (I), when heated above its m. p. Similarly other coumarins, having substituting groups in position 4, when sapond. with alkali, yield *colorless* salts of the corresponding coumarinic acids. Apparently these acids have the normal coumarin (not the *o*-quinone) structure. *Ethyl 4,5,7-trimethylcoumarin-6,8-dicarboxylate* (A), concentric needles, m. 131° , derived from (I) by the elimination of the 3-Ac group by Perkin's method (cf. *J. Chem. Soc.* 87, 109), yielded *3,5-dicarbethoxy- β ,4,6-trimethylcoumarinic acid*, plates, m. 122° , which when treated above its m. p. is reconverted into (A). α -Acetyl-3-carboxy-5-carbethoxy- β ,4,6-trimethylcoumarinic acid (B), plates from EtOH , m. 176° , was formed when (I) was boiled for several hrs. with 50% aq. NaOH . (B) was converted into *6-ethyl 8-hydrogen 3-acetyl-4,5,7-trimethylcoumarin-6,8-dicarboxylate* (C), small needles from EtOH , m. 235° . The elimination of the 3-Ac group from either (B) or (C) led to the formation of *3-carboxy-5-carbethoxy- β ,4,6-trimethylcoumarinic acid*, needles, m. 129° , which, when heated in sealed tubes with H_2O at 180° for 5 hrs., yielded *6-carbethoxy-4,5,7-trimethylcoumarin*, needles, m. 124° , which suffered no sapon. even on prolonged boiling with 50% aq. NaOH . On hydrolysis with 50% H_2SO_4 (I) yielded a mixt. of *4,5,7-trimethylcoumarin* (D) (cf. Clayton, C. A. 3, 776) and *3-carboxy- β ,4,6-trimethylcoumarinic acid* (E), needles, m. 300° (with evolution of CO_2 and the formation of (D)). (D) and (E) were sepd. by means of dil. Na_2CO_3 , in which (D) is insol. Although (E) titrates as a dibasic acid and exhibits great stability when the CO_2H group is free, its *di-ammonium salt* when heated loses NH_3 and an attempt to prep. its Ag salt led to the production of *silver 4,5,7-trimethylcoumarin-8-carboxylate* (F). On attempting to obtain the corresponding free carboxycoumarin from (F), (E) was regenerated. When treated with EtI in Et_2O (F) yielded the *8-carbethoxy-4,5,7-trimethylcoumarin*, laminas, m. 133° , reconverted into (E), when boiled with aq. NaOH . (D), when dissolved in warm aq. KOH , and the soln. carefully acidified at 0° , yielded *β ,4,6-trimethylcoumarinic acid*, very unstable needles, m. 128° , which rapidly passed back into (D) on standing at room temp. (I) in hot POCl_3 , when treated with an equiv. amt. of PCl_5 , forms a purple soln. from which Et_2O ppts. an unstable blue substance, which on treatment with EtOH is converted into *ethyl 2-chloro- α -acetyl-3,5-dicarbethoxy- β ,4,6-trimethylcoumarin*

somate, oil, boils with decompn., passing into (II) when treated with aq. NaOH. Br in CHCl_3 , acting upon (I) or upon (A), forms *ethyl 3-bromo-4,5,7-trimethylcoumarin-6,8-dicarboxylate*, microneedles, m. 114° , which when boiled with alc. KOH gave rise to *4-carbethoxy-6-carboxy-2,3,5-trimethylcoumarilic acid* (III), flakes, m. 197° . (D) absorbs Br with the formation of *3-bromo-4,5,7-trimethylcoumarin*, plates from EtOH, m. 163° , which when boiled with aq. KOH and the soln. acidified, yields *2,3,5-trimethylcoumarilic acid*, m. 149° . On nitration with $\text{HNO}_3\text{-H}_2\text{SO}_4$ mixt. below 0° , (D) in H_2SO_4 yields *6-nitro-4,5,7-trimethylcoumarin*, colorless needles, m. 208° , from which no corresponding coumarinic acid could be obtained. If this nitration is carried further by using an excess of nitrating mixt., and keeping the resulting soln. at room temp. for 12 hrs., the *3,6,8-trinitro-4,5,7-trimethylcoumarin*, cream-colored, flattened needles, m. 225° , was formed. The latter, when sapon. with alkali, yielded *ω,3,5-trinitro-2-hydroxy-α,4,6-trimethylstyrene*, $\text{O}_2\text{NC}:\text{C}(\text{OH})\cdot\text{C}(\text{CMe}:\text{CHNO}_2):\text{CMe}\cdot\text{C}(\text{NO}_2):\text{CMe}$,

nodules from C_6H_6 , m. 103° . By nitrating (I) or (A) at 0° with $\text{H}_2\text{SO}_4\text{-HNO}_3$ mixt., *ethyl 6-nitro-4,5,7-trimethylcoumarin-8-carboxylate*, needles from glacial AcOH, m. 170° , was formed. (E) when boiled in 35% HNO_3 yielded *6,8-dinitro-4,5,7-trimethylcoumarin*, needles from abs. EtOH, m. 203° , which on boiling with aq. KOH forms *3,5-dinitro-β,4,6-trimethylcoumarinic acid*, yellow, m. 182° (decompn.).

LOUIS E. WISE.

Preparation of allyl alcohol. FREDERICK D. CHATTAWAY, Oxford. *J. Chem. Soc.* 107, 407-10 (1915).—An improved method for the prepn. of $\text{C}_3\text{H}_5\text{OH}$ is described. A mixt. of 500 g. anhydrous (CO_2H) and 500 g. glycerol was heated in partial vacuum on a H_2O bath for 4-5 hrs. (or longer) until HCO_2H ceased to distil over. The mixt. was then very gradually heated to 240° under ordinary pressure, the flask being fitted with a 4-bulb Young fractionating column. At $220\text{-}5^\circ$ CO_2 was given off and a mixt. (A) of approx. equal amts. of $\text{C}_3\text{H}_5\text{OH}$ and $\text{HCO}_2\text{C}_2\text{H}_5$ distd. over, leaving in the distg. flask a residue (B) containing somewhat <50% of the glycerol originally used. Practically no acrolein was produced. (A) was treated with 50 g. NaOH in 1 l. H_2O (to hydrolyze the formate), allowed to stand for 12 hrs. at room temp., and finally distd. The 1st 300 cc. of distillate contained all of the $\text{C}_3\text{H}_5\text{OH}$, which after fractionation (using a 12-bulb Young column) yielded about 200-10 g. of a $\text{C}_3\text{H}_5\text{OH-H}_2\text{O}$ mixt., b₇₆₀ $87\text{-}8^\circ$, which may be dehydrated by means of anhydrous K_2CO_3 , yielding approx. 150 g. pure $\text{C}_3\text{H}_5\text{OH}$. To obtain $\text{HCO}_2\text{C}_2\text{H}_5$, the sapon. of (A) is omitted and the mixt. distd., using a 12-bulb fractionating column, and collecting the fraction b. below 87° , drying over CaCl_2 , redistg. and collecting the fraction b₇₆₀ $82\text{-}3^\circ$. The yield of pure ester was about 90 g. The residue (B) may be made up to 500 g. with more glycerol, 500 g. (CO_2H), added and the process repeated. After 4-5 repetitions of this kind it is best to discard the residue, as it shows a tendency to froth during the preliminary heating. C.'s process gives a nearly theoretical yield of $\text{C}_3\text{H}_5\text{OH}$, calc. on the basis of the glycerol actually entering the reaction, the yield being twice as great as the best that can be obtained by Tollens and Heninger's method.

LOUIS E. WISE.

Hydrazides and azides of organic acids. XXIX. Hydrazide and azide of adipic acid, pimelic acid and trans-hexahydroterephthalic acid. THEODORE CURTIUS. Heidelberg. *J. prakt. Chem.* 91, 1-38 (1915).—I. (With ERNST DARMSTÄDTER). A study of the conversion of di- CO_2H acids, by means of their hydrazides and azides, into di- NH_2 compds. having 2 less C atoms: $(\text{CH}_2)_4(\text{CO}_2\text{H})_2 \longrightarrow (\text{CH}_2)_4(\text{NH}_2)_2$; $(\text{CH}_2)_5(\text{CO}_2\text{H})_2 \longrightarrow (\text{CH}_2)_5(\text{NH}_2)_2$; $\text{C}_6\text{H}_{10}(\text{CO}_2\text{H})_2 \longrightarrow \text{C}_6\text{H}_{10}(\text{NH}_2)_2$. *Adipinyl dihydrazide* (a), $(\text{CH}_2)_4(\text{CONHNH}_2)_2$, was obtained in 90% yield by slowly dropping $(\text{CH}_2)_4(\text{CO}_2\text{Et})_2$ into 4 mols. of boiling $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$, and boiling the mixt. until crystals appeared. By repeating the operation with the filtrate a further amt. can be obtained;

lustrous leaves from H_2O or dil alc., m. 171° ; in H_2O it reacts alk., and reduces both Fehling soln. and $\text{AgNO}_3 + \text{NH}_4\text{OH}$, and yields N_2H_4 on boiling with HCl ; *hydrochloride*, by passing dry HCl into (a) in cold abs. alc., white powder, decomp. 275° ; *dibenzal derivative*, $(\text{CH}_2)_4(\text{CONHN}:\text{CHPh})_2$, by shaking (a) in H_2O with 2 mols. BzH , microscopic needles from AcOH , m. $215-6^\circ$; *silver salt*, by adding AgNO_3 in alc. to a mixt. of the benzal deriv. + EtONa in alc., decomp. $175-6^\circ$; *di-o-hydroxybenzal derivative*, from (a) and HOCH_2CHO , white ppt., m. 275° ; *dicinnamylidene derivative*, from (a) and $\text{PhCH}:\text{CHCHO}$, white powder from alc., m. $231-2^\circ$; *diacetone derivative*, m. 174° ; *diethylacetoacetate derivative*, white powder, m. 125° , which on warming with H_2O or alc. gives $\text{AcCH}_2\text{CO}_2\text{Et}$; *dibenzoyl derivative*, from (a) + NaOH and BzCl , microscopic needles from alc., m. 240° . *Secondary adipinyl hydrazide*,

$\text{HN.CO.}(\text{CH}_2)_4\text{.CO.NH}$, prepd. by adding I to (a) in warm abs. alc., white powder, m. 300° . If the reaction is carried on in dil. alc., only adipic acid is formed. *Adipinyl diazide* (b), $(\text{CH}_2)_4(\text{CON}_3)_2$, obtained by diazotizing (a) in cold H_2O , m. -1° , white crystals which explode when heated either directly or in H_2O . Addition of PhNH_2 to (b) in Et_2O yielded on standing 2 days at room temp. the *dianilide*, lustrous needles from PhNH_2 , m. 234° . The *ditoluidide*, similarly prepd. from $p\text{-MeC}_6\text{H}_4\text{NH}_2$, m. 216° , microscopic needles from AcOH . By adding abs. alc. to (b) in dry Et_2O *diethyl tetramethylenedicarbamate*, $(\text{CH}_2)_4(\text{NHCO}_2\text{Et})_2$, was obtained in 53% yield, long, fine needles, m. $85-6^\circ$. On hydrolysis with concd. HCl it gave a 43% yield of putrescine- HCl . *Adipinyl diglycine*, $(\text{CH}_2)_4(\text{CONHCH}_2\text{CO}_2\text{H})_2$, was prepd. by gradually adding, with shaking, (b) to a concd. soln. of glycine made alk. with NaOH , and acidifying with HCl ; prisms similar to hippuric acid, m. 190° . It acts as a dibasic acid, evolves CO_2 with Na_2CO_3 and gives a deep blue soln. with KOCi and PhOH ; *ammonium salt*, white crust, decomp. 205° , and loses NH_3 on boiling with H_2O ; *silver salt*, white ppt., darkens 220° , and m. 227° (decompn.); *ethyl ester*, from the Ag salt + EtI , bright yellow solid, m. 60° ; *amide*, from the ester + NH_4OH , white crystals, m. 132 . II. With HANS PRINGSHEIM. *Pimelyl dihydrazide*, prepd. similarly to (a), m. 182° , crystals from alc.; yield, 60%; *picrate*, small yellow leaves from dil. alc., m. 166° ; *dibenzal derivative*, white crystals from alc., m. 185° ; *di-o-hydroxybenzal derivative*, yellow flakes, m. 210° ; *diacetone derivative*, m. 129° ; *dibenzoyl derivative*, crystals from alc., m. 211° . The secondary hydrazide corresponding to that of (a) could not be prepd. in a similar way. In each attempt with various amts. of I, complete hydrolysis occurred, yielding pimelic acid. By diazotizing the hydrazide, the *diazide* (c), $(\text{CH}_2)_4(\text{CON}_3)_2$, was obtained, oil at room temp., which explodes on heating. With $p\text{-H}_2\text{NC}_6\text{H}_4\text{Me}$ it gave the *ditoluidide*, $(\text{CH}_2)_4(\text{CONHC}_6\text{H}_4\text{Me})_2$, lustrous leaves from alc., m. 206° . Heated with an excess of abs. alc., (c) gave *diethyl pentamethylenedicarbamate* in 42.8% yield, crystals from ligroin, m. 71° , which on hydrolysis with concd. HCl at 100° gave cadaverine. An attempt to condense (c) with glycine, as in the case of (b), was unsuccessful. *Succinyl diglycine*, prepd. from the corresponding diazide (cf. Curtius, *J. prakt. Chem.* 52, 221) and glycine, m. 205° , microscopic prisms from alc.; *ammonium salt*, white crystals from a c., m. 184° ; *silver salt*, white ppt.; *diethyl ester*, from the Ag salt + MeI , fine needles from ligroin + a few drops of alc., m. 116° ; *diamide*, plates, m. 234° . III. With RICHARD STANGASSINGER. *trans-Hexahydroterephthalyl dihydrazide* (d) was obtained in 94% yield by boiling for 2-2.5 hrs. on a H_2O bath 20 g. $\text{C}_6\text{H}_{10}(\text{CO}_2\text{Et})_2$ in 20 cc. alc. with 20 g. $\text{H}_2\text{N}_2\cdot\text{H}_2\text{O}$, fine needles from alc.; it reduces Fehling soln. and $\text{AgNO}_3 + \text{NH}_4\text{OH}$; *hydrochloride*, by passing HCl into (d) in alc., white powder, chars without m. The following derivs. of (d) were prepd. similarly to the corresponding derivs. of (a): *dibenzal derivative*, white insol. powder, m. above 300° ; *diacetone derivative*, hair-like needles from alc. + acetone; *diethylacetoacetate derivative*, white powder from alc., m. above 300° ; *disemicarbaside*, insol. powder m. above 300° ; *diaside*, micro-

scopic needles, m. 63° (decompn.). On standing *in vacuo* for 19 days it lost 2 mols. N, giving a product whose analysis agreed with that of the di-isocyanate; *diethyl trans-hexahydrophenylene-1,4-carbamate* (e), $C_8H_{10}(NHCO_2Et)_2$, needles, m. 236° ; *dimethyl ester*, large lustrous needles, m. $244-5^{\circ}$. By heating the diazide directly with $PhNH_2$ at 200° , the *diurea derivative*, $C_8H_{10}(NHCONHPh)_2$, was obtained, white, insol. powder, chars without melting. By carrying on the reaction in Et_2O or C_6H_6 , the *anilidourea derivative*, $PhNHCOC_8H_{10}NHCONHPh$, was obtained by extg. the reaction mixt. with alc., microscopic needles, m. above 300° . A compound, $CO(NHC_8H_{10}NHCONHPh)_2(?)$, insol. in alc., was also isolated, which in H_2SO_4 gives a deep red ring on addition of a few drops of $K_2Cr_2O_7$ soln. By dropping the azide in Et_2O into boiling H_2O , N and CO_2 are evolved, and on continued boiling for 16 hrs. and finally heating at 120°

for 8 hrs. the cyclic *diurea derivative*, $\overbrace{HN.C_8H_{10}.NH.CO.NH.C_8H_{10}.NH}$, was obtained. *trans-1,4-Diaminohexahydrobenzene hydrochloride*, prepd. either by heating (e) with concd. HCl for 7 hrs. at 120° , or by heating on a H_2O bath for 24 hrs., microscopic prisms. It differs from the *p*-diaminohexamethylene described by Bayer and Noyes (cf. *Ber.* 22, 2171 (1889)) in that it gives no coloration with $FeCl_3$; *chloroplatinate*; *picrate*, lemon leaves from H_2O , chars 275° ; *diacetyl derivative*; *dibenzoyl derivative*, white, insol. ppt., m. above 300° ; *free base*, by decomp. the HCl deriv. with NaOH, long prisms, m. $72-3^{\circ}$; t forms a carbonate with atm. CO_2 ; *sulfate*, long needles. **XXX. Formation of hydrazide-hydrazides and hydraziazides of tribasic acids.** *Ibid* 39-102. I. With EDMUND BOURCART. Tricarballic acid cannot be converted into $C_6H_5(NH_2)_3$ by the azide method (cf. *J. prakt. Chem.* 62, 232 (1900)), but tri-Et pyrazoline-3,4,5-tricarboxylate (a) can be converted into the corresponding tri- NH_2 deriv. Trimesic, hemimellitic and pyrazoletetricarboxylic acids, on the other hand, do not lend themselves to this reaction. Only the sym. tri- CO_2H acids form with $H_2N_2.H_2O$ hydrazides and azides of the types (b) and (c), resp., while those having 2 CO_2H groups in the *o*-position form hydrazihydrazides and hydraziazides of the type (I). The instability of 1,3,5- $C_6H_3(NH_2)_3$ probably explains why it cannot thus be obtained from trimesic acid. (a) was prepd. by allowing N_2CHCO_2Et to stand with cold di-Et fumarate; short needles from alc., m. 97° . By adding 10 g. of (a) in 30 g. hot alc. to 10 g. $H_2N_2.H_2O$ in 200 cc. of cold abs. alc., and allowing to stand for 1 hr., *pyrazoline-3,4,5-tricarboxyl trihydrazide*

(b), $\overbrace{(R = CONHNH_2) R.C:N.NH.CHR.CHR}$, is formed, white ppt., cannot be crystd. without decompn., becomes red $130-40^{\circ}$, m. 148° (decompn.). When heated with H_2O for 2-3 days, NH_3 is evolved, and on cooling a yellow acid seps.; *hydrochloride*, by adding cold, concd. HCl to (b), white, hygroscopic ppt., becomes yellowish red on standing; *sulfate* and *nitrate*, both unstable; *picrate*, small yellow needles; *sodium sulfate derivative*, white ppt., becomes red on standing; *chloroplatinate*; *cadmium chloride derivative*, white ppt. from (b) + $CdCl_2$; *tribenzal derivative* ($R' = PhCH:NNHCO$),

$\overbrace{R'C:N.NH.CHR'.CHR'}$, by shaking (b) in H_2O with BzH, white ppt.; *tri-p-nitrobenzol derivative*, white, light powder; *trihydroxybenzal derivative*, light yellowish powder, becomes red 130° ; *trivanillal derivative*, light, yellow powder, m. 139° (decompn.); *tripiperonal derivative*, white ppt.; *tricinnylamylidene derivative*, lemon, microcryst. powder; *trifarfuril derivative*; *triacetone derivative*; *triacetyl derivative*, by warming (b) with an excess of Ac_2O , white powder, becomes red $100-30^{\circ}$, m. 140° (decompn.); *triazide*

(c), $\overbrace{N_2OCC:N.NH.CH(CON_2).CHCON_2}$, by diazotizing (b) in dil. HCl, and extg. with Et_2O , viscous oil, very volatile *in vacuo* and explodes when heated; *trianilide*, from (c) in Et_2O and $PhNH_2$, amorphous ppt. from $CHCl_3$, does not m. below 300° ; *tri-p-toluidide*, amorphous ppt. On b. with abs. alc., for 2-3 hrs., (c) was converted into tri-

ethyl pyrazoline-3,4,5-tricarbamate, a viscous substance which could not be crystd.; on heating with 3-4 vols. concd. HCl for 24-36 hrs., at 60-70°, until evolution of CO₂ had entirely ceased, extg. with alc., filtering off the NH₄Cl and concg., a gelatinous residue was obtained whose properties and derivs. showed it to be chiefly *pyrazoline-3,4,5-triamine hydrochloride*; *picrate*, short yellow needles from H₂O, m. 180° (decompn.). Attempts to obtain the free base in pure form by decompn. of the picrate were unsuccessful. By diazotizing the HCl deriv., adding resorcinol and passing CO₂ through the resulting mixt., a dark brown, non-cryst. *dye* was obtained. Similarly, β -naphthol gave a brown *dye*. II. With LUDWIG H. HEYNEMANN. The tri-Et pyrazole-3,4,5-tricarboxylate (*d*), used for the following preps., was made from N₃CHCO₂Et and [: C(CO₂Et)]₃, according to the method of Buchner (cf. *Ber.* 22, 842). When allowed to stand with NH₄OH it gave the *triamide*, cryst. ppt., decompd. by boiling H₂O. (*d*)

was converted into the *trihydrazide* (*e*), H₂NNHCOC:N.NH.C(CONHNH₂):CCONH-NH₂, by the action of H₂N₂.H₂O in cold. abs. alc., microcryst. powder, does not m. below 300°, sol. in both dil. alks. and acids, and decompd. by boiling with H₂O. The following derivs. were prepd. from (*e*) and the corresponding aldehydes; *tribenzal derivative*, white, insol. ppt.; *trihydroxybenzal derivative*, yellow, flocculent ppt.; *tri-m-nitrobenzal derivative*, yellow ppt.; *tricinnamylidene derivative*, yellow, microcryst. powder from alc. There was also formed in this reaction *cinnamylideneazaine*, sepd. from the others by Et₂O, and the *cinnamylidenehydrazide derivative*, insol. in alc.

The *triaside*, N₃COC:N.NH.C(CON₂).CCON₂, prepd. by diazotizing (*e*), was obtained by slow evapn. from Et₂O as a cryst. solid. It explodes on heating, and is completely sapond. by cold dil. Na₂CO₃; *trianilide*, rosettes of needles from AcOH, does not m. below 270°. The white residue obtained by boiling the azide in Et₂O with abs. alc. for 6 hrs. did not respond to any of the tests for the expected triurethan. When 4 g. of (*d*) in abs. alc. is boiled for 3-7 hrs. with 2 g. H₂N₂.H₂O, the *hydrazide* (I)

is obtained in the form of the *diammonium salt*, needles from H₂O; with BzH it gave a *benzaldazine derivative*, m. 93°; *cinnamylidene derivative*, m. 162°. (I) was obtained by decompn. the di-NH₄ salt with dil. mineral acids. It shows both basic and acidic properties; *hydrochloride*, prepd. either by addition of concd. HCl or by passing dry HCl into the di-NH₄ salt in H₂O, white, cryst. powder; heated with dil. H₂SO₄ only the primary hydrazine residue is removed, while heating with concd. HCl in a closed tube removes the secondary groups with the formation of the *diacid ammonium pyrazole-*

tricarboxylate, HO₂CC:N.NH.C(CO₂H):CCO₂N₂H₄, silky needles, stable at 325°; shaken in H₂O with BzH, it yields, together with benzaldazine, the *free acid*, m. 230° (decompn.); *barium salt*, white powder. By shaking (I) in H₂O with BzH the *benzal derivative* was obtained as a white, flocculent ppt.; diazotized, (I) yields the *hydrazide* (*f*), yellow, flocculent ppt., which cannot be crystd., and is easily sapon. by alkalis; heated for 5 hrs. with PhNH₂ it yields the *hydrazianilide*. On boiling with H₂O (*f*) is converted into *pyrazolehydrazidic acid* (II), amorphous powder from H₂O, gives a white ppt. with HgCl₂ and (AcO)₂Pb. Heated with abs. alc., (*f*) yields a white cryst. powder, becomes brown 220°, and is sol. in strong acids and alkalies. It is probably the *hydrazidurethan*. III. With ALOYS J. SCHMITZ. The following derivs. of 1,3,5-

$C_6H_5(CO_2H)_3$ were prepd.: *Trimesyl trihydrazide* (g), $C_6H_5(CONHNH_2)_3$, by boiling for 12–16 hrs. $C_6H_5(CO_2Et)_3$ in abs. alc. with 8 g. $H_2N_2 \cdot H_2O$, microscopic crystals, does not m. below 300° ; *hydrochloride*, by passing HCl into (g) in alc., lustrous needles, unstable in the air, and loses H_2O at 100° ; *tribenzal derivative*, $C_6H_5(CONHN:CHPh)_3$, by direct heating of its components, powder by dissolving in AcOH and pptg. with H_2O , m. 224° ; *triaside*, by diazotizing (g) in dil. HCl, white flocculent ppt., explodes on heating or percussion; on boiling for 8 hrs. with H_2O , CO_2 , and N were evolved, but no other product was identified, while on boiling with alc., it yielded *triethyl benzenetri-carbamate* (h), $C_6H_5(NHCO_2Et)_3$, white ppt. by dissolving in alc. and pptg. with H_2O , m. $110-1^\circ$; *trianilide*, by heating the triazide with $PhNH_2$, brown ppt. from dil. AcOH, m. $118-20^\circ$ (decompn.). On heating (h) in alc. for 8 hrs. with dil. HCl at 100° , the expected $C_6H_5(NH_2)_3$ was not formed, but a compd. whose analysis agreed fairly closely with that of the *aminodiurethan*, $H_2NC_6H_5(NHCO_2Et)_2$, long needles by pptg. from alc. with H_2O , m. $172-3^\circ$. The following derivs. of $1,2,3-C_6H_3(CO_2H)_3$ were prepd.: $C_6H_3(CO_2Et)_3$ from acenaphthene according to the method of Graebe (cf. *Ber.* 25, 652; 26, 1797; *Ann.* 290, 206, 217); on heating in alc. with $H_2N_2 \cdot H_2O$ it yielded quant. *hemimellitethylhydrazide* (III), yellow powder, m. above 300° , gives ppts. with $CuSO_4$, $AgNO_3$, $HgCl_2$ and $FeCl_3$; *benzal derivative*, microcryst. powder, m. above 300° ; *hydraziaside*, white powder; *hydrazianilide*, yellow, cryst. powder; *urethan derivative*, white cryst. powder; *urea derivative*, by heating the hydraziazide with H_2O , monoclinic crystals from H_2O . Yield, 40%. Heated for 2 hrs. in a closed tube with concd. HCl, it was converted into *o*-aminophthalyl hydrazide. The latter on heating with concd. HCl for 30–40 hrs. at $145-50^\circ$ loses 1 mol. H_2N_2 salt, forming $1,2,3-H_2NC_6H_3CO_2H$, which is further converted into *m*- $H_2NC_6H_3CO_2H$ by loss of CO_2 .

D. BRREESE JONES.

Selenoaldehydes. L. VANINO AND A. SCHINNER. Munich. *J. prakt. Chem.* 91, 116–27 (1915).—Analogous to the formation of thioaldehydes by the action of H_2S on *O*-aldehydes, V. and S. have prepd. selenoaldehydes by means of H_2Se . *Selenoformaldehyde*, $HCHSe$, was obtained in 50% yield by passing H_2Se (prepd. by the action of H_2O on Al_2Se_3) into 36% $HCHO$ in 3 vols. concd. HCl. The soln. becomes turbid within 1 hr., and after standing 24 hrs. a white ppt. seps., which after filtering, washing with alc., and recrystg. from alc., forms difficultly sol. prisms m. 215° , and becomes green in sunlight. *Selenoacetaldehyde*, $MeCSeH$, was obtained by passing H_2Se into AcH in 3 vols. cold alc. satd. with HCl, and purified by dissolving in abs. alc. at 60° , and allowing to evap. slowly, needles, m. 139° . There was also formed a cryst. compound, m. $123-4^\circ$ from acetone, and m. 117° from $CHCl_3$. If the reaction is conducted in the absence of HCl, a viscous, oily product having an extremely disagreeable odor is formed, suggesting that, as in the case of $MeCSH$, different modifications of $MeCSeH$ are formed, depending on the conditions. *Selenobenzaldehyde* was obtained in 3 modifications: 21 g. BzH in 140 cc. abs. alc. treated with H_2Se turns yellow in a few min., then deep red, and finally yellow again with sepn. of a red flocculent ppt. After 2–3 hrs. a heavy red oil seps. whose analysis agrees with that of $PhCSeH$. From the yellow alc. soln. was obtained, in small yield, yellow prisms of the α -modification, $PhCSeH$, m. $83-4^\circ$, unstable toward light; β -modification, $(PhCSeH)_2 \cdot C_6H_6$, from H_2Se and BzH in abs. alc. satd. with HCl, golden needles from C_6H_6 , m. about 205° . Yield, 60%. By cong. the C_6H_6 filtrate from the β -deriv., and addition of much alc., the γ -modification, $PhCSeH$, seps. as fine, yellow needles, m. 166° . The β -deriv. yields, on heating at 310° with reduced Cu, stilbene in 55% yield, resembling in this respect $PhCSH$ (cf. H. Klinger, *Ber.* 9, 1895; 10, 1877 (1877)).

D. BRREESE JONES.

Mercury derivatives of aromatic amines. I. Contribution to the structure of primary and secondary *p*-aminophenylmercuric compounds. WALTER A. JACOBS

AND MICHAEL HEIDELBERGER. Rockefeller Inst. *J. Biol. Chem.* 20, 513-20(1915).—The monomol. structure of at least one mercuric aromatic amine was demonstrated by its reaction as a primary amine and of its Me deriv. as a secondary amine. *4-p-Dimethylaminobenzeneazophenylmercuric acetate*, from $p\text{-H}_2\text{NC}_6\text{H}_4\text{HgOAc}$ (A) and HNO_2 (this diazo soln. will be called (B)) and PhNMe_2 , brick-red crystals, m. 215° (uncor.), difficultly sol. except in HOAc , dyes silk bright yellow. *4-p-Diethylaminobenzeneazophenylmercuric acetate*, prepd. as the di-Me compd., orange-brown platelets, redden above 120° , m. $154.5\text{--}6^\circ$ (cor.). *4-p-Hydroxybenzeneazophenylmercuric acetate*, from (B) and PhOH , orange crystals, m. $218\text{--}9^\circ$ (cor.), dyes silk yellow in alk. soln. *4-o,p-Dihydroxybenzeneazophenylmercuric acetate*, from (B) and resorcinol, dark brown powder, darkens above 160° , decomp. $190\text{--}5^\circ$. *1-Amino-2-[p-naphthaleneazophenylmercuric acetate]-5-sulphonic acid*, from (B) and $\alpha,5\text{-C}_{10}\text{H}_6(\text{NH}_2)\text{SO}_3\text{H}$, brown-black, microcryst. powder, sol. in NaOH with deep maroon color, dyes silk orange. *4-o-Hydroxybenzylideneaminophenylmercuric acetate*, from (A) and $o\text{-HOC}_6\text{H}_4\text{CHO}$, deep yellow microcryst., darkens above 140° , m. about 185° (decompn.). *p-Methylnitrosoaminophenylmercuric acetate*, from $p\text{-MeNHC}_6\text{H}_4\text{HgOAc}$ and HNO_2 , m. $183\text{--}4^\circ$ (cor.). *3-Methyl-4-p-hydroxybenzeneazophenylmercuric acetate*, from $3,4\text{-Me}(\text{H}_2\text{N})\text{-C}_6\text{H}_3\text{HgOAc}$, HNO_2 and PhOH , m. $204.5\text{--}5.0^\circ$. I. GREENWALD.

The preparation and melting points of the higher aliphatic hydrocarbons. P. A. LEVENE, C. J. WEST AND J. VAN DER SCHEER. Rockefeller Inst. *J. Biol. Chem.* 20, 521-34(1915).—The normal aliphatic hydrocarbons with an even number of C atoms from C_{16} to C_{26} were prepd. Those from C_{16} to C_{22} were prepd. from the corresponding iodides by reduction with Zn and HCl ; the others from the iodides with $1/2$ the number of C atoms through the action of Mg in dry Et_2O . Hydrocarbons were also prepd. by reducing lignoceric, ceryl and melissyl alcs. Since the m. ps. differed from those of the normal hydrocarbons having the same number of C atoms, it is concluded that these hydrocarbons, and consequently the corresponding alcs. and acids, possess a branched C chain. The m. ps. were detd. in a H_2SO_4 bath with stirring arrangement, which was heated at the rate of 1° in 6 or 7 secs. for the last 15° . The consts. found for the normal compds. were: $\text{C}_{16}\text{H}_{34}\text{I}$, $b_{0.6}$ 152° ; $\text{C}_{18}\text{H}_{38}\text{I}$, $b_{1.0}$ 110° , m. 20° ; $\text{C}_{18}\text{H}_{37}\text{OH}$, $b_{1.6}$ 210° , m. 58.5° ; $\text{C}_{18}\text{H}_{37}\text{I}$, $b_{0.8}$ $169\text{--}70^\circ$, m. 34° ; $\text{C}_{18}\text{H}_{38}$, $b_{1.8}$ 177° , m. 28° ; $\text{C}_{19}\text{H}_{40}\text{CO}_2\text{H}$, m. 77° ; $\text{C}_{20}\text{H}_{42}\text{OH}$, $b_{0.3}$ 210° , m. $66\text{--}7^\circ$; $\text{C}_{20}\text{H}_{42}\text{I}$, $b_{0.5}$ 192° , m. 42° ; $\text{C}_{20}\text{H}_{40}$, $b_{0.6}$ 148° , m. 38° ; $\text{C}_{22}\text{H}_{46}\text{OH}$, m. $73\text{--}4^\circ$; $\text{C}_{22}\text{H}_{46}\text{I}$, m. 49° ; $\text{C}_{22}\text{H}_{46}$, m. 47° ; $\text{C}_{19}\text{H}_{39}\text{OH}$, $b_{0.8}$ 117° ; $\text{C}_{19}\text{H}_{39}\text{I}$, $b_{0.8}$ 117° ; $\text{C}_{22}\text{H}_{44}$, $b_{0.4}$ 199° , m. $59\text{--}60^\circ$; $\text{C}_{19}\text{H}_{39}\text{I}$, $b_{0.8}$ 128° ; $\text{C}_{22}\text{H}_{48}$, $b_{1.1}$ 224° , m. $64\text{--}5^\circ$; $\text{C}_{18}\text{H}_{32}\text{I}$, $b_{0.4}$ $138\text{--}9^\circ$; $\text{C}_{20}\text{H}_{42}$, $b_{1.0}$ 235° , m. $69\text{--}70^\circ$; $\text{C}_{22}\text{H}_{46}$, $b_{1.4}$ 245° , m. $74\text{--}5^\circ$; $\text{C}_{17}\text{H}_{36}\text{OH}$, m. 54° ; $\text{C}_{17}\text{H}_{36}\text{I}$, $b_{0.4}$ $158\text{--}9^\circ$; $\text{C}_{24}\text{H}_{50}$, $b_{1.0}$ 255° , m. $76\text{--}76.5^\circ$; $\text{C}_{24}\text{H}_{50}$, $b_{1.0}$ 265° , m. 78.5° . *Cerane*, from ceryl alc., is *isohexacosane*, $b_{0.7}$ 207° , m. 61° . *Mellisane*, from melissyl alc., is *isotriacontane*, $b_{0.3}$ 222° , m. $73\text{--}4^\circ$. The structure of lignoceric alc. and acid and the m. p. of tetracosane and isotetracosane have already been considered (*C. A.* 8, 3188). I. GREENWALD.

The quaternary salts of hexamethylenetetramine. I. Substituted benzyl halides and the hexamethylenetetramonium salts derived therefrom. WALTER A. JACOBS AND MICHAEL HEIDELBERGER. Rockefeller Inst. *J. Biol. Chem.* 20, 659-83(1915).—Substituted benzyl groups were in turn substituted in hexamethylenetetramine (a) for the purpose of prep. a new group of bactericides. The salts of these new derivs. of (a) were usually prepd. by boiling together in dry CHCl_3 (5-7 cc. per g. of (a)) equimol. amts. of the corresponding halides and of (a) until the sepn. of the products had reached a max. In some cases the mixt. was heated in a sealed tube at 100° for 30 min. This was then washed with CHCl_3 , then Me_2CO and dried over H_2SO_4 or CaCl_2 and paraffin. If pure materials were taken, the product was also pure. Recrystn. was usually impossible, as in H_2O or EtOH decompn. occurred and in other

solvents the preps. were not sufficiently sol. Yields were generally good. The m. p. was detd. by rapidly heating to within a few degrees, then more slowly. When H_2O solns. of these salts are warmed or allowed to stand, $HCHO$ is liberated and a product seps. as a colloidal suspension, as an emulsion of oil drops or as a cryst. ppt. These are sol. in acids and, so far as examd., consist chiefly of the methylene derivs. of the corresponding primary amines. The derivs. of (a) prepd. and the m. p. of the salt are given below. The salts, unless otherwise noted, are chlorides. Following these are the other new compds. prepd. in the course of the work and also new methods of prepg. and new const. for compds. already known. *o*-Methylbenzyl, 202-4°; *m*-methylbenzyl, 204-5°; *p*-methylbenzyl, turns yellow 186°, m. 198°; 3,5-dimethylbenzyl, 203-4°; *o*-xylene (dichloride), decomps. 162°; *m*-xylene (dichloride), m. 180-6°; mesityl (dichloride), decomps. 188-91°; β -naphthobenzyl, 190-5°; *o*-chlorobenzyl, m. 201-3° (decompn.); *p*-chlorobenzyl, m. 202-5° (decompn.); *o*-bromobenzyl, m. 183-6° (decompn.); *p*-bromobenzyl (impure?), m. 192° (decompn.); *p*-iodobenzyl (bromide), m. 181-2° (decompn.); *o*-cyanobenzyl, m. 183° (decompn.); *p*-cyanobenzyl, m. 193-3.5° (decompn.); *o*-nitrobenzyl, m. 178-9° (decompn.); *m*-nitrobenzyl, m. 199-202° (decompn.); *p*-nitrobenzyl, m. 173-4° (decompn.); 2,4-dinitrobenzyl, m. 178-9° (decompn.); *o*-acetylaminobenzyl, m. 180-2° (decompn.); *p*-acetylaminobenzyl, m. 175-7° (decompn.); 2-acetoxy-3,5-dimethylbenzyl, m. 158°; 2-hydroxy-3,5-dibromobenzyl, m. 173-4°; 2-acetoxy-3,5-dibromobenzyl, m. 151-3° (decompn.); 4-acetoxy-3,5-dibromobenzyl, m. 184-5°; 2-acetoxy-3,5-dimethyl-4,6-dibromobenzyl, m. 150-1°; 2-hydroxy-5-nitrobenzyl, m. 210° (decompn.); 3-nitro-4-acetoxybenzyl (iodide), m. 159° (decompn.); *o*-methoxybenzyl, m. 201-2° (decompn.); *p*-methoxybenzyl, m. 180-5° (decompn.); β -methoxy- α -naphthobenzyl, m. 185-6° (decompn.); 2-methoxy-5-nitrobenzyl, m. 191-5° (decompn.); 3-nitro-4-methoxybenzyl, m. 183-8°; *o*-ethoxybenzyl, m. 188-91° (decompn.); 3,4-methylenedioxybenzyl, m. 203-4°; 2,3-dimethoxybenzyl, m. 200-1° (decompn.); 3,4-dimethoxybenzyl, m. 187-8° (decompn.); 2-nitro-3,4-dimethoxybenzyl, m. 187-9° (decompn.); 3-methoxy-4-ethoxybenzyl, m. 178-81° (decompn.); 3-carboxy-4-hydroxybenzyl, m. 188-90° (decompn.); 3-carbomethoxy-4-hydroxybenzyl, m. 191-1.5° (decompn.); 2-hydroxy-3-carboxy-5-methylbenzyl, m. 179-81° (decompn.); 2-hydroxy-3-carbomethoxynaphthobenzyl, m. 195-8° (decompn.); 2-methoxy-5-carboxybenzyl, m. 204-5° (decompn.); 2-methoxy-5-carbomethoxybenzyl, m. 208-8.5° (decompn.); 3-aldehydo-4-hydroxybenzyl, m. 194° (decompn.); 2-hydroxy-3-methoxy-5-aldehydobenzyl, m. 163-4° (decompn.). *o*-Bromobenzyl chloride, from boiling o -BrC₆H₄Me and Cl, b₂₀ 124-6° (cor.); *p*-nitrobenzylpyridinium chloride, colorless, m. 204-7°; 3-nitro-4-hydroxybenzylpiperidine, from the benzyl chloride and piperidine (yield, 50%), m. 141-3°; 3-nitro-4-acetoxybenzylpiperidine hydrochloride, from above and AcCl, m. 178-9°; 3-amino-4-hydroxybenzylpiperidine dihydrochloride, from the NO₂ compd. and SnCl₄, decomps. about 180°; *o*-acetoxyesityl pseudochloride (2-acetoxy-3,5-dimethylbenzyl chloride), from the HO compd. and Ac₂O, m. 37.5-38° (cor.); 3-nitro-4-acetoxybenzyl chloride, from the HO compd. and Ac₂O, m. 59.5-60° (cor.); 3-nitro-4-acetoxybenzyl iodide, from the chloride and NaI, m. 65.5-68° (cor.); 3-nitro-6-acetoxybenzyl chloride, prepd. as the isomer, crystals with EtOH, softens 55°, m. 83° (cor.); β -methoxy- α -naphthobenzyl alcohol, from the amine and HNO₂, m. 100-1° (cor.); chloride, from the alc. and HCl; 2-methoxy-5-nitrobenzyl alcohol, from the aldehyde and NaOH, m. 124-5°; chloride, from the alc. and HCl, m. 50.5-1.0° (cor.); 3,4-O₂N(MeO)C₆H₂CH₂OH, from the aldehyde and NaOH, m. 59-60.5° (cor.); chloride, from the alc. and HCl, m. 86° (cor.); 2,3-(MeO)₂C₆H₂CH₂Cl, m. 69-70.5°; 2,4-dimethoxybenzyl alcohol, from the aldehyde and KOH, b₁₀ 177-9°; 2,3,4-O₂N(MeO)₂C₆H₂CH₂OH, from the aldehyde and KOH; chloride, from the alc. and HCl; 3,4-MeO(EtO)C₆H₂CH₂OH, from the aldehyde and KOH; chloride, b_{0.6-0.7} 127°, m. 42-42.5° (cor.); 2-hydroxy-3-carbo-

methoxynaphthobenzyl chloride, from $\alpha\text{-C}_{10}\text{H}_7\text{CO}_2\text{Me}$ (German Pat. 113,723, 1900-2), m. 164.5-6°. II. Monohaloacetylbenzylamines and their hexamethylenetetramonium salts. *Ibid* 685-94.—The chloroacetylaminos were prepd. by treating the amines with CH_2ClCOCl and KOH. These were then combined with (a). In some cases the Cl compds. failed to react, or the yield was poor. The I amine was then prepd. by treating with NaI. *Chloroacetylbenzylamine*, m. 93.5-4.5° (cor.); (a) derivative, m. 168-9°; *chloroacetyl-o-methylbenzylamine*, m. 107.5-8° (cor.); (a) compound, m. 152°; *p-acetylaminiodoacetylbenzylamine*, m. 205-6°; (a) compound, m. 165-6° (decompn.); *1-methyl-2-acetylaminochloroacetylbenzylamine*, m. 212.5-4°; *1-methyl-4-acetylaminochloroacetylbenzylamine*, m. incompletely 164-7°; resolidifies and m. 180-2°; (a) compound, m. 197-200°; *β -acetoxy- α -chloroacetylnaphthobenzylamine*, m. 169-70°; (a) compound, m. 175-6°; *β -acetoxy- α -iodoacetylnaphthobenzylamine*, m. 188-90° (cor.); (a) compound, m. 184-7° (decompn.); *2-acetoxy-5-nitrochloroacetylbenzylamine*, from the HO compd. and Ac_2O , m. 97.5-8° (cor.); *β -methoxy- α -chloroacetylnaphthobenzylamine* (a) compound, m. 112-20° (decompn.); *2-methoxy-5-nitrochloroacetylbenzylamine*, from the HO compd. and Me_2SO_4 , m. 120.5-1.5° (cor.); *1-acetyl-amino-4-ethoxy-chloroacetylbenzylamine* (a) compound, m. 169-70° (decompn.); *1,2-diacetoxychloroacetylbenzylamine*, from the di-HO compd. and Ac_2O , m. 86.5-7.5°; (a) compound, m. 174° (decompn.); *1,2-dimethoxychloroacetylbenzylamine*, from the di-HO compd. and Me_2SO_4 , m. 117-7.5° (cor.); (a) compound, m. 160-1° (decompn.); (a) compound of ethyl *m-chloroacetylaminomethylbenzoate*, m. 122-4°; ethyl *m-iodoacetylaminomethylbenzoate*, from the Cl compd. and NaI, m. 116-6.5° (cor.); *m-chloroacetylaminomethylbenzoyl chloride*, from the acid and PCl_5 , m. 78-9° (cor.); *diethylaminoethyl m-chloroacetylaminomethylbenzoate*, m. 69-70.5°; (a) compound, m. 125-30°; *chloroacetylaminomethylbenzamide*, m. 171-2.5° (cor.); (a) compound, m. 183° (decompn.). I. GREENWALD.

The Beckmann rearrangement. IV. Acyl derivatives of the substituted imido acids. MITSURU KUHARA AND KANOICHIRO SUITSU. *Mem. Coll. Sci. Kyoto Imp. Univ.* 1, 24-34 (1914); cf. *C. A.* 1, 2882; 5, 1278; 8, 2876.—In order to throw more light on the mechanism of the rearrangement, K. and S. have investigated several acyl derivs. of substituted NH-acids, e. g., PhC(OAc):NPh (a) may be considered, according to K. and S., as the intermediate compd. formed in the rearrangement of $\text{Ph}_2\text{C:NOH}$ to BzNHPh by the action of AcCl . *Phenylbensimidooacetate* (a) was prepd. by the action of AcOAg on PhCCl:NPh , in cold Et_2O . On evap. the Et_2O , after filtration from AgCl , a small amt. of BzNHPh first sepd., then some BzNACPh , and finally there remained a thick, yellow oil. This could not be obtained sufficiently pure for analysis on account of its instability, but was characterized as (a) by its chem. behavior. When treated in Et_2O with dry HCl , a yellow *hydrochloride* (b) was formed, which was soon decompd. by moisture into BzNHPh , PhNH_2 , and AcOH . (b) yielded BzNHPh at once, when heated in CHCl_3 at 60°. (a), however, showed no perceptible change even when heated for 2 hrs. at 160-170°. On hydrolysis (a) gave AcOH and BzNHPh . If PhCCl:NPh was treated with AcONa instead of AcOAg , none of (a) was formed, but entirely its isomer, BzNACPh . By the action of BzOAg on PhCCl:NPh a yellow oil, probably *phenylbensimidobenzoate*, PhC(OBz):NPh (c), and Bz_2NPh were obtained; the reaction thus took the same course as with AcOAg . Carefully purified PhCCl:NPh in Et_2O with AcSK gave entirely *phenylbensimidothioacetate*, PhC(SAc):NPh (d), amber-yellow monoclinic prisms from $\text{CHCl}_3\text{-Et}_2\text{O}$. When less carefully purified imido chloride was employed, (d) was mixed with varying quantities of its isomer *acetylphenylthiobenzamide*, PhCSNPhAc (e), deep orange-red needles, m. 78.5-9.5°. This isomer is probably formed under the influence of acid in the impure imido chloride for (d) may be readily converted into (e) by the action of POCl_3 , AcCl , BzCl or HCl . Both (d) and (e) on hydrolysis with dil. acids or alkalies are converted

into PhCSNHPH and AcOH . (*d*) was also obtained by treating the Na salt of PhCSNHPH , suspended in xylene, with AcCl , while (*e*) was formed when the Et_2O soln. of PhCSNHPH was treated with AcCl in the presence of K_2CO_3 . Both a yellow and red product resulted from the action of BzSK on PhCCl:NPh in petr. ether in the presence of anhydrous K_2CO_3 at ordinary temp. (1 month). The yellow product, assumed to be *phenylbenzimidothiobenzoate*, PhC(SBz):NPh , was not further described, but the red substance, *benzoylphenylthiobenamide*, PhCSNPhBz , was purified and analyzed; it m. $110-1^\circ$. V. The rearrangement of diphenyl ketoxime benzenesulfonyl ester and synthesis of phenylbenzimidobenzenesulfonate. MITSURA KUHARA, KAORU MATSUMIYA AND NAOHICO MATSUNAMI. *Ibid* 105-13.—*Diphenylketoximebenzenesulphonate*, $\text{Ph}_2\text{C:NO}_2\text{SPh}$ (*a*) is shown to undergo spontaneous mol. rearrangement into *phenylbenzimidobenzenesulphonate*, $\text{PhC(O}_2\text{SPh):NPh}$ (*b*), thus giving a possible explanation of the mechanism of the Beckmann rearrangement. $\text{Ph}_2\text{C:NONa}$, previously prepd. by Spiegler (*Ber.* 17, 812), was obtained in larger yield by treating $\text{Ph}_2\text{C:NOH}$ in Et_2O with Na. H was liberated with the production of a small amt. of Ph_2CHNH_2 , but the yield of Na salt was good. This salt, treated at ordinary temp. with PhSO_2Cl in abs. Et_2O , was converted into (*a*), which sepd. on evapn. of the Et_2O , in colorless crystals, m. 62° with some change, after recrystn. from Et_2O . By alc. KOH. (*a*) is hydrolyzed to $\text{Ph}_2\text{C:NOH}$ and PhSO_2K ; when heated above its m. p. rearrangement instantaneously takes place with explosive violence and hissing, with the formation of (*b*) as a thick yellow liquid. This change takes place slowly when (*a*) is allowed to stand in the solid state, in CHCl_3 soln., or on exposure to ultraviolet rays. Treated with H_2O , (*b*) decomp. into BzNHPh and PhSO_2H ; the same change takes place slowly when exposed to the air, but by the continued action of moisture further decompn. occurs with the formation of PhNH_2 , BzOH and PhSO_2H , the latter sepg. in needles as its PhNH_2 salt. The constitution of (*b*) was further proved by synthesis from PhCCl:NPh and PhSO_2Ag in petr. ether and the identity of this product with that obtained by the rearrangement of (*a*) proved by a comparison of the absorption spectra.

NORMAN A. SHEPARD.

The use of hydrochloric acid in the estimation of certain forms of organic nitrogen. W. A. DRUSHEL AND M. M. BRANDEGGER. *Yale Univ. Am. J. Sci.* 39, 398-404 (1915).—The N of aliphatic nitriles, amides, imides and CN-substituted esters may be quant. fixed as NH_4Cl by heating with an excess of HCl in sealed tubes for 2-3 hrs. at 200° ; 0.1-0.3 g. of the substance for analysis was introduced into a combustion tube, 2-5 cc. of HCl (d. 1.2) added and the tube sealed. After heating for 2-3 hrs. at 200° , the contents were evapd. on the H_2O bath and the last traces of HCl removed by heating the residue in the oven for 5 min. at 110° . Under these conditions the excess of HCl was completely removed and no measurable quantity of NH_4Cl was lost by volatilization. The N may then be estd. by titration with 0.1 N AgNO_3 , using $\text{K}_2\text{Cr}_2\text{O}_7$ as an indicator. The N values obtained agreed well with the theoretical amts. The N of glycocoll may be similarly estd., but a temp. of 200° must be maintained for 3-4 hrs.

NORMAN A. SHEPARD.

Mustard oils in cruciferae. J. J. BLANKSMA. *Pharm. Weekblad* 51, 1383-91 (1914); *Chem. Zentr.* 1915, I, 261-2.—The mustard oils in certain cruciferae have been isolated and identified by their reaction with PhNHNH_2 (cf. Busch, *C. A.* 4, 593). *Cochlearia officinalis*. The finely powdered plants were treated with H_2O and distd. with steam. 100 g. blossoms gave 62 mg. $\text{C}_4\text{H}_9\text{NCS}$; 100 g. leaves gave 9 mg.; 100 g. stems, 4 mg. and 100 g. of the whole plant, 30.5 mg. mustard oil. The distillate was *d*-rotatory and gave with alc. NH_3 *d*-sec.-butylthiourea, m. 137° ; with PhNHNH_2 in hot alc. is produced *d*-sec.-butylphenylthiosemicarbasine, $\text{PhNHNH.CS.NH.C}_4\text{H}_9$, crystals from benzine or dil. EtOH , m. 135° ; $[\alpha]_D^{20} = +20^\circ$ (in EtOH). With MePhN -

NH_2 is obtained *1-methylphenyl-4-d-sec.-butylthiosemicarbazine*, needles, m. 112° , $[\alpha]_D = +19.9^\circ$ (in EtOH). *Cochlearia danica*. The oil obtained by steam distn. consists chiefly of *d*-MeEtCHNCS; from 100 g. were obtained 6-7 mg. oil. *Cardamine pratensis*. The oil contains *d*-MeEtCHNCS. *Capsella bursa pastoris* gives no mustard oil, but a volatile compd. containing S; it gives with $\text{NH}_3\text{-AgNO}_3$ a black ppt.; on oxidation with HNO_3 , H_2SO_4 is produced; the content of fatty oil is 36.2% ($d_{44} 0.932$, $n_D^{16} 1.4798$, sapon. no. 190.4, acid no. 5.6, I no. 115; the fatty acid m. 26.4° ; mol. wt. of fatty acid 288). The seeds of *Tropaeolum majus* contain PhCH_2NCS ; with PhNHNH_2 this gives *1-phenyl-4-benzylthiosemicarbazine*, m. 158° , crystals. From the mother liquor of the alc. soln. was isolated a compd., m. 115° , which was apparently *4-NH_2NPhCSNHCH_2Ph* (cf. Dixon, *J. Chem. Soc.* 61, 1021). The distillates from *Lepidium campestre*, *Nasturtium amphybiun*, and *Draba verna* L. exert a strong retarding action on the growth of molds. The allyl mustard oil isolated from *Sinapis nigra* gives with PhNMeNH_2 *1-methylphenyl-4-allylthiosemicarbazine*, crystals from dil. EtOH, m. 90° . E. H.

The position of the organic chemical industry. WILLIAM H. PERKIN. *J. Chem. Soc.*, 107, 557-78(1915).—Presidential address before the British Chem. Soc. The address is with reference to the industry in Gt. Britain. E. J. C.

Synthesis of pentazole compounds. I. J. LIFSCHITZ. Univ. Zurich. *Ber.* 48, 410-20(1915).—Cyanotetrazole in 10 parts alc. cautiously warmed with 2 mols. $\text{N}_2\text{H}_4\text{-H}_2\text{O}$ until the violent boiling and evolution of NH_3 have ceased and the product has changed to a yellow cryst. mass quant. gives *pentazidoacetic hydrazidine* (a), $\text{N:N:N:NCH}_2\text{C}(\text{NH})\text{NHNH}_2$, light yellow threads insol. in all org. media, does

not m. 310° , deflagrates at higher temps. Boiled 6-8 hrs. in about 10 parts of 30-40% KOH it gives a light yellow K salt of *pentazidoacetic hydrazide*, $\text{N}_5\text{CH}_2\text{C}(\text{OH})\text{:NNH}_2$, obtained as a yellow ppt. by adding AcOH to the aq. soln. of the salt; it holds moisture tenaciously and drying at 110° seems to cause some decompn.; it suddenly decomp. without m. at a definite, quite high temp., gives CuO with boiling CuSO_4 ; with aq. BaCl_2 containing a little AcOH it gives a *barium salt*, $(\text{C}_2\text{H}_4\text{ON})_2\text{Ba}$, sepg. from H_2O in brown-yellow leaflets, exploding violently on heating. The K salt, treated with boiling KMnO_4 until the color persists for 1 min., freed of excess of KMnO_4 with alc., filtered, concd., cooled, acidified with HNO_3 treated with AgNO_3 , filtered, dissolved in boiling $\text{C}_6\text{H}_5\text{N}$ containing a little alc., cooled and covered with Et_2O , gives *silver pentazidoacetate*, $\text{C}_2\text{H}_5\text{O}_2\text{N}_5\text{Ag.EtOH}$, cryst. powder insol. in dil. acids, sol. in NH_3 . Small amts. of (a), suspended in a concd. soln. of a large excess of NaNO_2 and treated with concd. HCl, give a very moderate yield of *isonitrosopentazidoacetic hydrazide* (c), $\text{N}_5\text{C}(\text{:NOH})\text{CONHNH}_2$, crimson crystals from alc., detonates without m. on heating, also obtained from (a) with AmNO_2 in alc. and HCl and from (b) with HNO_3 , sol. in alc. and H_2O with crimson color and strong acid reaction, gives with aq. AgNO_3 a deep violet flocculent Ag salt and with boiling BaCl_2 a *triazolone barium salt*, $(\text{N}_5\text{C:N.NH.N:CO-})_2\text{Ba}$, orange cryst. powder, explodes violently on heating, re-

generating (c) with excess of acids. In dil. aq. alkali (c) dissolves with a red color which, however, quickly changes to yellow-green; alc. or aq. mineral acid solns. are also unstable, the former giving *isonitrosopentazidoacetic acid* (d), yellow leaflets with golden luster, reduces $\text{NH}_3\text{-AgNO}_3$ after a few min. boiling; a hot aq. suspension treated with HNO_3 and AgNO_3 gives a yellow flocculent ppt. (probably $\text{N}_5\text{C}(\text{:NOH})\text{CO}_2\text{Ag}$) which, on boiling under the soln., changes to a wine-red cryst. salt, $\text{N}_5\text{CH:NOAg}$ or $\text{N}_5\text{CO}_2\text{Ag}$, insol. in hot concd. NH_3 , explodes on heating, only slowly attacked by hot aq. KOH; on boiling, AgO is formed and the colorless filtrate with HNO_3 and AgNO_3 gives a white

flocculent ppt., apparently *silver pentasole*, AgN_3 . Alc. AgNO_3 likewise gives with (d) a yellow ppt. which, however, at once begins to turn brown. (d) dissolves in warm aq. KOH with dark yellow greenish color; on boiling a short time, acidifying with concd. HNO_3 and adding an excess of aq. AgNO_3 a voluminous flocculent salt, $\text{AgN}_3 \cdot \text{AgO}_2 \cdot \text{CCO}_2\text{H}$ is pptd. Apparently the KOH converts (d) into $\text{N}_3\text{COCO}_2\text{H}$ which is decompd. by the acid into N_3H and $(\text{CO}_2\text{H})_3$.

CHAS. A. ROUVILLER.

***o*-Aldehydehydophenylglycine. II. A new and rational indole synthesis.** W. GLUUD. Davy Faraday Lab., Roy. Inst., London. *Ber.* 48, 420-5 (1915); cf. *C. A.* 7, 3124.—It has now been found that *o*- $\text{OHCC}_6\text{H}_4\text{NHCH}_2\text{CO}_2\text{H}$ (a) can be obtained in good yield (about 9 g.) by boiling 15 g. of $\text{HON}:\text{CHC}_6\text{H}_4\text{NHCH}_2\text{CONH}_2$ (b) in 375 cc. H_2O for 3 hrs. with 75 g. NaHSO_3 , slowly adding 300 cc. of 5 *N* H_2SO_4 and boiling until the odor of SO_2 has almost disappeared, the (a) at once sepg. on cooling. It is also obtained in 9.7 g. yield from 12 g. $\text{HON}:\text{CHC}_6\text{H}_4\text{NHCH}_2\text{CO}_2\text{H}$ warmed on the H_2O bath with 200 cc. of cold satd. H_2SO_3 until just dissolved, treated with 100 cc. more H_2SO_3 , allowed to stand 3 hrs., filtered from the sepd. (a) (8 g.) and boiled to expel the SO_2 . Other oximes can be decompd. in the same way; *e. g.*, camphorquinone is obtained in 50% yield from 1 g. isonitrosocamphor allowed to stand loosely stoppered for 24 hrs. in 40 cc. cold satd. H_2SO_3 on the H_2O bath. From 10 g. freshly fused NaOAc , 20 cc. Ac_2O and 3 g. (a) warmed 1 min. on the H_2O bath, boiled 10 min. under a reflux condenser, cooled, treated with H_2O , then slowly with 100 cc. of 33% KOH and distd. with steam is obtained 1.5 g. indole. *o*-Aldehydehydophenylglycine phenylhydrazone, plates from MeOH, m. 217° (foaming). Calcium *o*-aldehydephenylamin oacetate, $\text{C}_{18}\text{H}_{16}\text{O}_4\text{N}_2\text{Ca} \cdot 3\text{H}_2\text{O}$, intensely yellow crystals. Copper salt, yellowish brown; cobalt salt, yellowish; mercury salt, yellowish to red-yellow; ferrous salt, light yellow; ferric salt, brownish; silver salt, intensely yellow but soon decolorizing; barium salt, intensely yellow. Acetyl-oxime, $\text{AcON}:\text{CHC}_6\text{H}_4\text{NHCH}_2\text{CO}_2\text{H}$, plates from H_2O , m. $149-50^\circ$ (foaming). III. A class of new derivatives of *o*-aldehydehydophenylglycine. *Ibid* 425-32.—When 2 g. (b) is warmed on the H_2O bath with 20 cc. of 40 vol.-% HCHO until just dissolved and at once poured upon ice there seps. 1.8 g. of anhydroformaldehydephenylglycinamide-*o*-aldoxime, $\text{CH}_2\text{CH}(\text{NO}) \cdot \text{C}_6\text{H}_4\text{NCH}_2\text{CONH}_2$, yellow plates or tables from alc., m.

$233-4^\circ$ (foaming), hydrolyzed by boiling *N* NaOH to the glycine-aldoxime, intensely yellow rectangular or quadratic plates or tables from alc., m. 210° (decompn.), sol. in cold NaHCO_3 . If H_2SO_3 is used instead of NaOH, the product of hydrolysis is (a). Anhydroacetaldehydephenylglycinamide-*o*-aldoxime, m. about 233° (0.2 g. yield from 0.5 g. (b)); glycine-aldoxime, in 0.9 g. yield from 2 g. (a) and 10 cc. AcH after 10 min., 4- or 6-sided tables from alc., m. about 190° (foaming), easily sol. in cold NaHCO_3 ; it is also obtained in 0.45 g. yield from 0.5 g. (a) and 6 cc. paraldehyde. Anhydropropionaldehydephenylglycine-*o*-aldoxime, in 0.6 g. yield from 1.5 g. (a) and 7 cc. EtCHO after 14 hrs., intensely yellow prisms, m. 175° (foaming). From 20 g. $(\text{CHO})_2 \cdot 2\text{NaHSO}_3$, H_2O boiled 10 min. with 150 cc. of *N* H_2SO_4 , then treated with 4 g. (b), boiled until almost all is dissolved, filtered hot and at once cooled with ice is obtained 3 g. of a condensation product, $\text{C}_{11}\text{H}_{11}\text{O}_2\text{N}_3$, intensely yellow 6-sided columns from H_2O , decolorizes about 205° , soon blackens completely and decomp. $218-25^\circ$, depending on the manner of heating, sol. in concd. H_2SO_4 . Anhydrobenzaldehydephenylglycine-*o*-aldoxime, in 2 g. yield from 1.5 g. (a) and 12 cc. BzH after 18 hrs., intensely yellow lancet-shaped crystals, m. $204-5^\circ$ (foaming), sol. in NaHCO_3 . Cinnamaldehyde compound, in 0.6 g. yield from 1 g. (a) and 6 cc. $\text{PhCH}:\text{CHCHO}$ after some hrs., yellow spears, m. $166-7^\circ$ (foaming). Furfural compound, in 2 g. yield from 1.5 g. (a) and 8 cc. furfural after 24 hrs., 4-sided plates from MeOH, m. $195-7^\circ$ (decompn.).

C. A. ROUVILLER.

Note on the bromination of *o*-nitrotoluene and on *o*-nitrobenzylpyridinium chloride. WILHELM GLUUD. Davy Faraday Lab., London. *Ber.* 48, 432-5(1915).—In the presence of Fe as catalyst, a mol. of Br can easily be introduced into *o*-MeC₆H₄NO₂, a good yield being obtained of a mixt. of the isomeric MeBrC₆H₄NO₂, the chief constituent being 4,2-Br(O₂N)C₆H₃Me, probably mixed with the 6-Br compd. The former crysts. after several weeks from the middle fractions. With KMnO₄, the greater part of the mixt. remains unchanged, the KMnO₄ being used up at the expense of the Br(O₂N)C₆H₃CO₂H formed, but 2 cryst. derivs. were obtained from the small amt. of acids formed; *vis.*, 4,2-Br(O₂N)C₆H₃CO₂H, and a much more sol. acid, m. 178°, possibly 6-bromo-2-nitrobenzoic acid. MnO₂ in dil. H₂SO₄ also gives only a small amt. of the former acid; CrO₃ in concd. H₂SO₄ yields Br(O₂N)C₆H₃CHO which with alkali in acetone gives dibromindigo. From 137 g. *o*-O₂NC₆H₄Me, 200 g. Br and 20 g. Fe nails warmed 1-2 min. to incipient evolution of HBr, allowed to react 30-45 min., again warmed till the evolution of HBr is complete, shaken several times with H₂O, taken up in much petr. ether, washed with 2 *N* NaOH and H₂O, dried and distd. is obtained 155 g. b. 250-63°. Contrary to Lellmann and Pekrun, who describe *o*-nitrobenzylpyridinium chloride as wine-yellow and m. 76° (*Ann.* 259, 57), G. obtains the compd. from Kahlbaum's O₂NC₆H₄CH₂Cl as colorless crystals with 1 H₂O from alc.-Et₂O, m. 104-5° and (anhydrous) 203-4°. CHAS. A. ROUVIER.

The orcinolphthaleins, the orcinoltetrachlorophthaleins, and some of their derivatives. W. R. ORNDORFF AND E. R. ALLEN. Cornell Univ. *J. Am. Chem. Soc.* 37, 1201-58(1915).—Previous work on these compds. is reviewed at length. The present work was undertaken to det. the influence of introducing negative groups into phthalein mols., to observe to what extent these compds. and their derivs. exist in colored and colorless forms and whether they agree with our present theories of color, and to study the conditions affecting the formation of isomers and the methods of sepg. them. Pure anhydrous orcinol m. 107° (Hesse, *J. prakt. Chem.* [2] 57, 270, gives 100-1°). A number of expts. with concd. and fuming H₂SO₄, P₂O₅, HPO₃ and ZnCl₂ as condensing agents showed that as regards the crude yield and purity of the orcinolphthaleins, fuming H₂SO₄ gives the best results, then concd. acid and P₂O₅; the latter gives a relatively higher yield of the γ -phthalein (under the best conditions, 87 g. (=71.5%) crude product was obtained from 50 g. C₆H₄(CO)₂O, 87 g. orcinol and 90 g. P₂O₅ heated 2 hrs. at 180-90°; 50 g. of this product on purification yielded 5.7, 22.0, 14.0 and 1.5 g. of α -, β - and γ -phthaleins and tar, resp.). HPO₃ is nearly worthless; with ZnCl₂, the heating must be continued longer than 2 hrs. or carried to a temp. higher than 120°. When 20 g. C₆H₄(CO)₂O and 34 g. orcinol fused at 120° were treated with 18 cc. fuming H₂SO₄ (15% SO₃) the temp. rose to 200° but returned to 120° in 20 min.; it was kept at this point for 2 hrs., poured into H₂O, broken up, dissolved in alkali, pptd. with acid, filtered and dried. The crude product (47.5 g. =97.9%) gave 11.7, 25.0 and 6.0 g. of the α -, β - and γ -phthaleins, resp. To sep. the isomers, the cold alk. filtered soln. of the crude product is slowly poured into a large vol. of dil. mineral acid, the mixt. shaken with a large amt. of Et₂O, the Et₂O filtered, shaken with about 1/3 its vol. of *N* soda and the soda, which contains all but traces of the γ -, considerable β - and some α -compds., is shaken with fresh portions of Et₂O. The α - and β -compds. are sepd. by shaking the filtered Et₂O soln. with *N* soda; the soda soln. is shaken with a small portion of fresh Et₂O; the original Et₂O soln. is shaken with fresh soda and the 2nd soda soln. extd. with the same small portion of Et₂O used for the 2nd extn. of the 1st soda soln. The process is repeated until a fresh portion of the soda when shaken with the original Et₂O is only faintly colored and this color is at once removed when the soda soln. is shaken with the smaller portion of Et₂O. The α -compd. remains in the Et₂O, the β -compd. in the soda.

The soda ext. of the Et_2O soln. of the original crude product, containing the γ - and a little of the β -product, is acidified and the γ -compd. purified by Kehrman's HCl method (C. A. 7, 2555). The β -compd. is finally purified by K.'s alc. NH_3 method. The α -phthalein as obtained above is pptd. from alkalies by acids in pure white flocks and after crystn. from MeOH and glacial AcOH seps. from warm dil. EtOH or MeOH solns. on the addition of H_2O in nearly rectangular plates (from the alc. and AcOH it seps. with 1 mol. solvent). It dissolves easily in dil. alkalies with purplish red color, with difficulty in aq. NH_3 and only on warming in the alkali carbonates, these solns. being wine-red. Dry NH_3 and HCl do not attack it. In more concd. alkalies (50%) it is sol. with a pure blue color, and, when perfectly pure, in alc. NH_3 without color; on diln. with H_2O , the soln. becomes reddish violet and after a time the phthalein crystals out and the soln. becomes colorless. Boiled 1 hr. with 1 part NaOAc and 7 parts Ac_2O it gives a *diacetate*, prisms from alc. or AcOEt , shrinks above 230° , m. $246-7^\circ$; from C_6H_6 it seps. with 2.78% solvent of crystn.; it is insol. in alkalies. *Dibenzoate*, obtained by shaking with BzCl and dil. alkali until the mixt. is only slightly violet, needles from C_6H_6 or alc., m. 277° (Meyer, Ber. 29, 2627 (1896), gives 284°), insol. in alkalies, less easily hydrolyzed than the diacetate. The tetra-Br deriv. prepd. by M.'s method, when dissolved in boiling alkali (slightly stronger than N) loses some Br. Another prepn. (pale yellow microscopic prisms) when extd. with boiling C_6H_6 yielded a white product differing from M.'s tetra-Br compd. in that it dissolves with difficulty in cold aq. alkalies with pure blue color; on warming more dissolves and the color becomes intensely blue, fading on cooling but not becoming violet, and a white cryst. substance seps., presumably a salt of the carbinolcarboxylic acid. With dry NH_3 , the tetra-Br compd. forms a pale blue *diammonium salt*, $\text{C}_{22}\text{H}_{15}\text{O}_8\text{Br}_4(\text{NH}_3)_2$, quickly losing NH_3 in the air. *Tetrabromo- α -orcinolphthalein diacetate*, microscopic prisms from C_6H_6 , m. 297° (slight decompn.), insol. in alkalies. *α -Orcinolphthalein hydrochloride*, from the phthalein in alc. and dry HCl at 0° , dark red microscopic needles, losing its HCl and becoming colorless after 45 min. at 178° or on warming in H_2O ; it is also formed, without dissolving, when the phthalein is treated with fuming HCl but not with dry HCl gas. Colorless mono-K *α -orcinolphthaleincarbinolcarboxylate* (cf. Baeyer, C. A. 4, 2124), obtained from the phthalein in alc. slowly treated with 0.5 N alc. KOH , white cryst. powder, losing H_2O and alc. after 0.5 hr. at 120° in H and becoming markedly dark bluish wine-red; in the air it loses all the alc. and the resulting lavender compd. contains 1 H_2O ; the substance dried only 0.5 hr. is hygroscopic and again becomes nearly colorless on absorbing moisture; if the heating is continued 1.5 hrs. longer, the salt becomes slightly brownish and is no longer hygroscopic. The colorless salt dissolves with difficulty in H_2O with wine-red color; on boiling or long standing, the dil. soln. becomes colorless and the lactoid phthalein seps. When 5 g. of the phthalein in 50 cc. alc. is added to 5 g. K_2CO_3 in 250 cc. of boiling 50% alc. and allowed to stand 48 hrs. a *monopotassium salt*, $\text{C}_{22}\text{H}_{15}\text{O}_8\text{K} \cdot 2\text{H}_2\text{O}$, seps. in microscopic purplish red needles, partly sol. in H_2O with wine-red color; when dried, it shows no tendency to absorb moisture and becomes colorless. When boiled with a large amt. of H_2O , the wine-red soln. becomes colorless and the phthalein seps.; the colorless supernatant liquid contains free alkali, hence the decolorization is due to hydrolysis. This red salt is the one which Baeyer assumed to be the di-K salt. B.'s supposed tetra-K salt was obtained fairly pure by adding 5 g. phthalein in 100 cc. alc. to 75 cc. of 1:1 KOH dild. to 150 cc. with H_2O and heated to 85° , distg. off about 85 cc. and cooling; the blue crystals proved to be a *dipotassium salt* with 1 H_2O , sol. in H_2O with purplish red color; they are also obtained by pouring 2.5 g. of the pure phthalein diacetate in 900 cc. of hot alc. into 7.5 g. KOH in 100 cc. of boiling alc., boiling a short time, distg. off 0.5 of the alc. and allowing to stand overnight. On boiling in much H_2O , the salt behaves

like the 2 mono-K salts. The mother liquors from which it seps. yield the *tripotassium carbinolcarboxylate*, colorless needles with 8.56-8.83% H_2O , behaves like the other K salts in boiling H_2O . The β -phthalein is pptd. by H_2O from hot MeOH or EtOH in both colorless and colored needles, but from cold MeOH only in white needles containing 1 mol. MeOH or both MeOH and H_2O ; it attains const. wt. after 1 hr. at 120° without becoming colored, but after 0.5 hr. more at 185° it isomerizes into the yellow quinoid form, obtained in 6-sided plates by dissolving in boiling alc., adding an equal vol. of H_2O and continuing the boiling. The phthalein dissolves in NH_3 , alkalis and alkali carbonates with intense cherry-red color and in alc. NH_3 with red color changing to blood-red on addition of H_2O . Dry NH_3 does not act on the quinoid form but the dry lactoid form absorbs nearly 1 mol. of dry NH_3 gas, forming a colorless compd. which loses all of its NH_3 at 130° or after several weeks in the air, in the latter case forming the phthalein hydrate. The phthalein is pptd. from alk. solns. by AcOH in white, by mineral acids in yellow flocks, the color of the latter being due to the presence of a small amt. of a quinoid salt. The white ppt. with AcOH is the phthalein hydrate, which loses its H_2O at 150° and isomerizes into the yellow form at 185° . The pptd. hydrate probably contains a small amt. of AcOH; when boiled in aq. suspension, it slowly goes over into the yellow form, the solvent action of the small amt. of AcOH probably lowering the transition temp.; the change into the yellow form can also be effected by boiling the air-dried hydrate in C_6H_6 . The yellow ppt. obtained with mineral acids becomes colorless on standing or warming and consists of the lactoid phthalein and its hydrate. When boiled with glacial AcOH, the hydrate only partly dissolves, but both the part remaining undissolved and that sepg. from the hot soln. are found to consist of the quinoid phthalein, whereas the cold mother liquors on long standing deposit a white microcryst. compd., $\text{C}_{22}\text{H}_{16}\text{O}_5\cdot\text{AcOH}$, which gives the quinoid phthalein at 185° . β -Orcinolphthalein diacetate, needles from C_6H_6 , m. $226-7^\circ$. Dibenzoate, needles from C_6H_6 , m. $234-5^\circ$ (Meyer gives $244-5^\circ$). Tetrabromo- β -orcinolphthalein absorbs 3-4 mols. of dry NH_3 in 8 hrs., yielding an almost black, unstable salt. With $\text{Ac}_2\text{O}\cdot\text{NaOAc}$ is obtained the *diacetate*, $\text{C}_{22}\text{H}_{10}\text{O}_7\text{Br}_4\text{Ac}_2$, needles from AcOEt, m. $266-7^\circ$. β -Orcinolphthalein hydrochloride, bright red, microscopic, diamond-shaped plates, loses its HCl at 175° and becomes yellow. The purified γ -phthalein dissolves in alkalis with a clear yellow color and only faint fluorescence which is much increased by the addition of alc. Towards concd. alkalis it behaves like fluorescein; it dissolves in NH_3 and alkali carbonates and bicarbonates with evolution of CO_2 , in alc. NH_3 with red color and strong greenish fluorescence; the soln turns yellow and less fluorescent when dild. with H_2O . From the alcs. on addition of H_2O it seps. with 1 mol. of alc. (plates with EtOH, cubes with MeOH); these crystals become bright golden yellow when heated to const. wt. at 110° and then grayish white at 185° . Meyer's dark orange product from AcOH is obtained only with impure phthalein. Hydrate, from the phthalein in dil. soda and dil. AcOH, white flocks turning bright yellow when dehydrated at 70° or boiled with H_2O , giving rhomboidal plates in the latter case. Diacetate, needles from C_6H_6 , m. $206-7^\circ$. Dibenzoate, needles from C_6H_6 -alc., m. $284-5^\circ$ (slight carbonization). Tetra-Br deriv.; *diacetate*, rhomboidal plates from alc., turns pink above 240° , colorless above 270° , m. $282-3^\circ$. The phthalein absorbs 2 mols. dry NH_3 in 17 min., forming an unstable orange *diammonium salt*, while the tetra-Br compd. absorbs approx. 4 mols. in 3 hrs. and becomes dark red. The phthalein also combines with 1 mol. of dry HCl gas without much change in color. In the prepn. of the orcinoltetrachlorophthaleins from $\text{C}_6\text{Cl}_4(\text{CO}_2\text{H})_2$ and orcinol, ZnCl_2 at $160-70^\circ$ was found to be the best condensing agent (yield of crude product, 85%); this is dissolved in cold *N* alkali, pptd. with dil. mineral acid, extd. with a large vol. of Et_2O , the Et_2O shaken with $1/4$ its vol. of *N* soda, which removes the γ - and a small amt. of the β -phthalein; the

latter is removed by extg. with several portions of fresh Et_2O . From the Et_2O solns. the β -compd. is removed by several shakings with soda, the α -compd. by extg. with NaOH . α -Orcinol-tetrachlorophthalein after crystn. from AcOEt , MeOH and EtOH is still straw-colored and contains 1 mol. EtOH , dissolves in alks. with almost pure blue color, only slightly in aq. NH_3 and soda, in alc. NH_3 without color, the soln. turning blue on addition of H_2O and the colorless phthalein sepg. after several days. *Diacetate*, rhombs, m. 292° . β -Phthalein, becomes faintly pink at 150° , decomps. in hot alk. soln. with elimination of Cl and formation of a compd. sepg. on acidification in dark red flocks; the phthalein dissolves in alkalies with a smudgy red color and is pptd. by acids as the white *hydrate*; in alc. NH_3 it dissolves with a deep red color. *Diacetate*, m. 239° . γ -Phthalein, purified through the diacetate, seps. from $\text{MeOH-H}_2\text{O}$ in white flocks with $2\text{H}_2\text{O}$ or 1 MeOH ; its dil. alk. solns. are yellow with green fluorescence; the alc. NH_3 solns. are reddish yellow with greenish fluorescence. *Diacetate*, m. $252-3^\circ$, seps. from C_6H_6 in long flat needles. The absorption of the phthaleins in 4 mols. KOH (aq. in the case of the α -, alc. in that of the β - and γ -compds.) was detd.; the following are the wave lengths of the points of minimum transmission of the α -, β - and γ -compds., resp. Orcinol-phthaleins, 0.528, 0.536, 0.498; orcinol-tetrachlorophthaleins, 0.562, 0.554, 0.521; tetrabromo-orcinol-phthaleins, 0.572, 0.576, 0.529; γ -tetrabromo-orcinol-tetrachlorophthalein, 0.555. The transmission curves are reproduced. O. and A. conclude that the structures assigned by Meyer and by Baeyer to the isomeric orcinol-phthaleins are in accord with all the known facts. B.'s explanation of the changes of color undergone by the α -phthalein when treated with alkalies is untenable. O. and A. believe that the phthalein is a pseudo acid existing in tautomeric forms, (I)

colorless, stable, and (II), colored, labile. The violet color first observed on treatment with alkalies is due to the mono-K salt of (II); alc. destroys the color because it favors the conversion of the salt of (II) into the colorless mono-K salt of the carbinol acid (III); with more alkali, both of these salts give the blue di-K salt of (II), while with a large excess of alkali, the colorless tri-K salt of (III) is formed. Boiling H_2O hydrolyzes

all these salts to (II) which crysts. as the insol. (I). For the colored form of the β -phthalein, the p -quinoid structure is given the preference, because the α -phthalein exists only in the lactoid, the γ -compd. only in the quinoid form. Why the lactoid form of the β -phthalein absorbs NH_3 and the quinoid form does not (just the contrary of what would be expected from the resp. resemblance of the 2 forms to the α - and γ -phthaleins) it is not possible to say. The o -quinoid form assigned by Kehrmann to the γ -phthalein is probably erroneous in view of the resemblance of the compd. to fluorescein. The colorless hydrates, alcoholates and AcOH compds. are considered as derivs. of the lactoid form (IV) ($\text{X} = \text{H}, \text{Me}, \text{Et}, \text{OAc}$). The colored hydrochlorides are quinoid derivs., either oxonium (o - in the case of the α -, o - or p - in that of the β -, and p - in that of the γ -compd.) or carbonium. CHAS. A. ROUILLER.

o - and p -Chlorobenzoyl-lactic esters and some of their derivatives. LAMBERT THORP AND E. R. BRUNSKILL. *J. Am. Chem. Soc.* 37, 1258-64 (1915); cf. *C. A.* 7, 1492.—To 0.5 g. of a soln. of 20.7 g. Na in 320 cc. alc. is added 58.5 g. $\text{AcCH}_2\text{CO}_2\text{Et}$, cooled to 5° , slowly treated below 12° with 28.25 cc. of $o\text{-ClC}_6\text{H}_4\text{COCl}$, then after 0.5

hr. with 80 cc. more of the NaOEt soln. and 14.12 cc. of $\text{ClC}_6\text{H}_4\text{COCl}$ and the process repeated 3 more times, 0.5 of the remaining portion of the 2 reagents being used each time; after 24 hrs. in the cold there is obtained 123 g. of the white *sodium salt*, $\text{ClC}_6\text{H}_4\text{C(ONa):CacCO}_2\text{Et}$; 120 g. of this in 600 cc. H_2O is kept 2-3 hrs. at $40-50^\circ$ with 54 g. NH_4Cl and 60 cc. of concd. NH_3 and then extd. with Et_2O , giving 70 g. of *ethyl o-chlorobenzoyleacetate*, pale yellow viscous oil, $d_4^{25} > 1$, cannot be distd. even under 30 mm.; 54 g. boiled with 240 cc. H_2O and 60 cc. of concd. H_2SO_4 until the evolution of CO_2 ceases (10-2 hrs.), extd. with Et_2O , shaken with 10% KOH , washed with H_2O and dried, gives 80% of *o-chloroacetophenone*, b_m 227-8°, n_D^{25} 1.685, d_4^{25} 1.1884; *oxime*, silky needles from 50% alc., m. 103° . From 10 g. of the ketone slowly added to 100 g. HNO_3 (d. 1.52) below 5° , allowed to stand 3 hrs. in a freezing mixt. and poured upon 500 cc. of ice H_2O is obtained 85% of *2-chloro-5-nitroacetophenone*, prisms from alc., m. 62° . *Ethyl p-chlorobenzoyleacetate*, obtained like the *o*-compd. except that the $\text{ClC}_6\text{H}_4\text{COCl}$ was used in Et_2O soln. (the *sodium salt* is yellow), prisms from dil. alc., m. 38° , gives with 2 mols. of 10% KOH at room temp. the white *potassium salt*, crystals from alc., m. 265° (decompn.), while 3.5 g. allowed to stand 3 days with 2.4 g. KOH in 50 cc. H_2O , filtered, extd. with Et_2O to remove traces of ester and of ketone and acidified, gives *p-chlorobenzoyleacetic acid*, crystals from Et_2O -ligiro, decomp. into the ketone when heated slowly but m. 232° when heated quickly; 20 g. added to 2.05 g. Na in 35 cc. alc., cooled, treated slowly with 17.6 g. BzCH_2Br , warmed 15 min. on the H_2O bath, dild. with H_2O and extd. with Et_2O , gives 50% of *ethyl phenacyl-p-chlorobenzoyleacetate*, $\text{ClC}_6\text{H}_4\text{COCH(CH}_2\text{Bz)CO}_2\text{Et}$, prisms from dil. alc., m. 63° ; 35 g. boiled 2 hrs. with 13.6 g. KOH in 300 cc. H_2O and 100 cc. alc. gave a poor yield of *4-chlorodiphenacyl (a)*, pearly leaflets from alc., m. 114.5° . *Ethyl p-chlorophenacylbenzoyleacetate*, obtained in 75% yield from $\text{ClC}_6\text{H}_4\text{COCH}_2\text{Br}$, NaOEt and $\text{BzCH}_2\text{CO}_2\text{Et}$ after 0.5 hr. on the H_2O bath, needles from alc., m. 92° , yields 50% of (a) with alc. KOH . C. A. R.

A comparison of the optical rotatory powers of the alpha and beta forms of certain acetylated derivatives of glucose. C. S. HUDSON AND J. K. DALE. *J. Am. Chem. Soc.* 37, 1264-70(1915).—According to H.'s views (*C. A.* 3, 882) if the mol. rotations of α - and β -glucose penta-acetates are represented by $(A + B)$ and $(-A + B)$, A being the rotation due to the end asym. C atom and B that due to the rest of the mol., then $(A' + B)$ and $(-A' + B)$ will represent the rotations of α - and β -tetra-acetyl-methylglucosides, and the sum of the rotations of the 2 penta-acetates should equal that of the 2 methylglucosides. Schliephacke found that this was not the case in C_6H_6 (*C. A.* 5, 467), but the α -methylglucoside forms a cryst. compd. with C_6H_6 and has a greater sp. rotation (173°) in this solvent than in alc. (137°) (van Charante, *Rec. trav. chim.* 21, 42 (1902)) while the β -form has nearly identical rotations in the 2 solvents. The rotations of the 4 compds. were accordingly detd. in various solvents with the following resp. results (av. mol. rotations at 20° for Na light): C_6H_6 , 37,800, 1,100, 63,530, -8,290; CHCl_3 , 39,600, 1,500, 47,300, -6,600; 99.5% AcOH , 42,400, 1,600, 48,500, -7,100; 50% AcOH , 42,200, 1,200, 45,800, -8,130; MeOH , 40,800, 1,900, 49,200, -7,890; EtOH , 39,400, 740, 49,500, -8,910 (Tanret's value for the α -penta-acetate in C_6H_6 (*Bull. soc. chim.* [3] 13, 261 (1895)) is probably too high). In MeOH , EtOH and CHCl_3 , therefore, the sums of the rotations of the 2 pairs of isomers agree quite well. The difference between the mol. rotations of the α - and β -glucose penta-acetates ($2A$) in CHCl_3 is 38,100 while for the 2 cellose octa-acetates (Schliemann, *C. A.* 5, 1276) it is 33,200; this divergence from the theory suggests that the octa-acetates have not yet been obtained in a pure or fully sepd. condition. A repetition of the work of Behrend and Roth (*Ann.* 213, 369 (1904)) furnished an even more nearly quant. proof than their own of the correlation of α - and β -glucoses with the α - and β -penta-acetates; from 50 g. Ac_2O , 67 g. com. pyridine bases and 10 g. α -glucose kept

24 hrs. at 0° was obtained 19.8 g. penta-acetate with a sp. rotation of 94° in CHCl₃ while under the same conditions the β -compd. yields 20.5 g. penta-acetate with a rotation of 5.8°. ZnCl₂ can be used instead of C₂H₅N; to 4 g. ZnCl₂ in 40 cc. Ac₂O at 0°, 10 g. α -glucose is slowly added and the mixt. kept at this temp. 5 hrs. with occasional shaking; 2.85 g. sugar remains undissolved and the filtrate, on dropping into H₂O, soon deposits 7.15 g. penta-acetate with a rotation of 92° in C₆H₆; the mother liquors are extd. with CHCl₃, the CHCl₃ evapd. nearly to dryness and the residue poured into H₂O; 3.64 g. more acetate, with a rotation of 82°, is obtained; extn. of these 2nd mother liquors with CHCl₃ yields 2.26 g. of a very viscous syrup. If the time of reaction is increased to 45 hrs., only 0.33 g. glucose remains undissolved and there are obtained 15.20 and 3.03 g. of penta-acetates with rotations of 78° and 59°, resp., and 1.30 g. of syrup; during this long reaction period, some of the α - has evidently been converted into the β -acetate. As a rule, when the acetylation mixt. is constantly stirred for 8 hrs., 10 g. glucose will give 13 g. acetate with a rotation of 83°, from which the pure α -acetate can be readily prepd. by crystn. from alc. From 10 g. β -glucose under the same conditions are obtained, after 5 hrs., 2.73 g. undissolved sugar, 10.75 and 2.22 g. of acetate with rotations of 8.7° and 18°, and 1.06 g. syrup; after 24 hrs., 0.43 g. glucose, 15.10 and 3.43 g. acetate with rotations of 14° and 43°, and 1.20 g. syrup; after 8 hrs., 17 g. of acetate with a rotation of 17°. The pure α -penta-acetate m. 112-3°; the β -compd., 132°; α -tetra-acetylmethylglucoside m. 100-1°; the β -compd. m. 104-5° (all cor.).

A. GENERAL.

FRANK P. UNDERHILL.

Oxaluria. E. PINCUSOHN. *Deut. med. Wochschr.* 41, 132-4(1915).—Dogs kept in N equil. received purines *per os*. The oxalic acid of the urine was slightly increased. After injection of eosin and exposure to intense illumination, the oxalic acid was increased without addition of purines to the diet; on addition of purines the increase was much more marked. On feeding xanthine under these conditions the oxalic acid was increased. Guanine *per os* did not lead to an increase of oxalic acid, but it seems that it was not resorbed. Uric acid *per os* with or without illumination did not give a definite result. Uric acid given intravenously increased the oxalic acid excretion without sensitization and illumination. Nucleic acid given subcutaneously did not give an increased oxalic acid excretion within the period of illumination, but did so during the following days.

S. AMBERG.

The influence of the hydrogen ion concentration upon the optimum temperature of a ferment. A. COMPTON. *Proc. Roy. Soc. London (B)* 88, 408-17(1915); cf. C. A. 8, 935; 9, 327.—Expts. on maltase show that the optimum temp. is dependent on the H⁺ conc. of the medium. Thus by increasing the H ion conc. from 10^{-7.3} to 10⁻⁵ it is possible to change the optimum temp. of the enzyme from +47° to +35.5°. Hence it is very important in stating the optimum temp. of an enzyme to state at the same time the H⁺ conc. of the medium serving to det. it.

The organic phosphoric acid of wheat bran. IV. The occurrence of inositol triphosphate in wheat bran. R. J. ANDERSON. *J. Biol. Chem.* 20, 463-73(1915).—Pure wheat bran was extd. with 0.2% HCl and the ext. pptd. with Ba(OH)₂. After 6 pptns. from HCl soln. with Ba(OH)₂ and the same number of pptns. with EtOH, the substance was dried. Upon extn. with H₂O, a little over half went into soln. The insol. material was freed of Ba with H₂SO₄ and the filtrate pptd. with Cu(OAc)₂. The ppt. was filtered, washed and decompd. with H₂S. Upon addition of strychnine and concg., needle-shaped crystals sepd. These soften at 200° but do not melt completely at a much higher temp. The strychnine was pptd. from the soln. of this salt by NH₄OH and the residual strychnine extd. with CHCl₃. The Ba salt was then pptd. in the usual manner. Comp. apparently is C₆H₇O₁₈P₃Ba₃. This was dissolved in 1% HCl and pptd. with EtOH. Comp. of ppt. apparently is C₁₈H₂₄O₄₈P₃Ba₃. From this, by treatment with H₂SO₄, Cu(OAc)₂ and H₂S, was obtained the free *inositol triphosphate*, C₆H₁₅O₁₈P₃, a colorless syrup, sol. in H₂O and EtOH. It does not ppt. with NH₄ molybdate nor with AgNO₃ (unless neutralized with NH₄OH), and ppts. with egg albumen only very slowly.

I. GREENWALD.

The hydrolysis of phytin by the enzyme phytase contained in wheat bran. R. J. ANDERSON. *J. Biol. Chem.* 20, 475-81(1915).—The chief products of the hydrolysis of phytin by the phytase in wheat bran are inorganic phosphoric acid and certain intermediate compds. These are apparently identical with the inositol tri-, di-, and monophosphates isolated from exts. of wheat bran. (Cf. C. A. 8, 3310 and preceding abstr.) Since the soln. contained free inositol and no unchanged phytin, it is evident that a part of the phytin was completely hydrolyzed and that all was at least partially hydrolyzed.

I. GREENWALD.

The hydrolysis of the organic phosphorus compound of wheat bran by the enzyme phytase. R. J. ANDERSON. *J. Biol. Chem.* 20, 383-91(1915).—The max. activity of the phytase of wheat bran occurs in the presence of 0.1% HCl or of 0.2% HOAc. With increasing conc. of HCl, the activity rapidly diminishes and with 0.5% HCl there is practically no hydrolysis. The enzyme is destroyed by boiling H₂O or by short exposure to 0.5% HCl or to 0.25% NH₃. About 11% of the total sol. P of wheat bran is inorganic.

I. GREENWALD.

Phytin in wheat bran. R. J. ANDERSON. *J. Biol. Chem.* 20, 494-500(1915).—Using 1% HCl as the extg. fluid, A. succeeded in preparing from wheat bran cryst. Ba salts of the comp. C₆H₁₂O₂₄P₃Ba₃·8H₂O and (C₆H₁₁O₂₄P₃)₂Ba₇·14H₂O, identical with the tribarium and heptabarium phytates obtained from oats, corn, cottonseed meal and commercial phytin.

I. GREENWALD.

The auxo-lipase of serum. KWANJI TSUJI. King's College, London. *Biochem. J.* 9, 53-65(1915).—T. gives the name "auxo-lipase" to the substance in the serum which accelerates the fat-splitting power of pancreatic exts. The "auxo-lipase" not only accelerates the action of active lipase but also activates inactive lipase, and this to a greater degree than the coenzyme itself. It is quite stable, and is not destroyed at 60-100°. Boiling, or addition of alc. or colloidal Fe, ppts. the substance with the proteins. Dialysis alters its activity but slightly, thereby suggesting its colloidal nature. Unlike the inorg. constit. of the coenzyme of lipase, those of the serum not only fail to produce an accelerating effect but even inhibit lipoclastic activity, thus furnishing evidence against the identity of auxo-lipase and coenzyme. The fact that auxo-lipase is resistive to heat does not lend support to Mellanby and Woolley's theory (C. A. 8, 3584) that the increase of lipoclastic power on the addition of serum to pancreas exts. is due to the protection of the lipase from the action of trypsin by the antitrypsin contained in the serum.

The specificity of caseinogens. A comparative study of the caseinogens of the cow and the sheep. H. W. DUDLEY AND H. E. WOODMAN. Leeds. *Biochem. J.* 9, 97-102(1915).—Evidence is produced in favor of the specificity of caseinogens by a study of the amino acids obtained from "racemized" caseinogen. If caseinogen is dissolved in dil. alkali and the soln. allowed to stand at 37° for about three weeks the value of the optical rotation falls practically to a const. The protein is then said to be "racemized," and the amino acids obtained on hydrolysis are either inactive, partially active, or fully active. Tyrosine obtained from "racemized" cow caseinogen is inactive, but that from "racemized" sheep caseinogen is active. Also, lysine from the protein of the cow is inactive, while that from the protein of sheep shows $\frac{2}{3}$ of its activity. According to Dakin (*C. A.* 7, 489) amino acids whose carboxyl groups are free and which therefore may occupy terminal positions at the ends of peptide chains, are incapable of racemization, while those whose carboxyl groups are united in actual peptide linkages, and are therefore probably situated within the chains, may undergo racemization. The optical activity or inactivity of the amino acids among the hydrolytic products of a "racemized" protein will therefore give some clue to the original position of these acids in the protein molecule.

B. HOROWITZ.

Colloidal swelling of wheat gluten. FRED W. UPSON AND J. W. CALVIN. *J. Am. Chem. Soc.* 37, 1295-304(1915).—The gluten was prepd. by washing the starch from flour with distd. H_2O , pressing between glass plates and cutting out disks; these were weighed to a cg., placed 2 hrs. in the soln. under investigation, drained on a Buchner funnel and weighed again. Solns. of lactic acid, AcOH and HCl, varying from 0 to 0.5 *N*, were used. The amts. of H_2O absorbed with increasing concn. of the acid are plotted in the form of curves. The absorption increases at first very rapidly, the max. being obtained at 0.01-0.02, 0.04 and 0.005 *N* concns. of the 3 acids, resp., then falls with further increase in the acid concn., quite rapidly in the case of HCl, more slowly in that of lactic acid and still more with AcOH. In 0.2 and 0.5 *N* HCl, moist gluten loses H_2O . Addition of salts (K tartrate, K_2HPO_4 , KCl, $CaCl_2$, $NH_4CH_2CO_2H$) to the lactic acid solns. greatly reduces the swelling, the decrease in H_2O absorption increasing with the concn. of the salt; in the more concd. phosphate and tartrate (0.02-0.04 molar) the gluten disks lose wt. For 0.02 molar concns. of the salts in 0.01 *N* lactic acid, the order of the salts as regards their effect in diminishing absorption is: chloride, tartrate, phosphate. The H_2O absorption is reversible; disks which in 0.002-0.5 *N* AcOH have absorbed H_2O not only reassume their original wt., but also their original appearance and physical properties (toughness, elasticity) in 0.1 *N* K_2HPO_4 . Rise in temp. increases the swelling in acids, the wts. of H_2O absorbed per g. moist gluten in H_2O , 0.01 *N* HCl, lactic acid and AcOH being 0.06, 1.47, 1.65 and 1.68 g. at 24° and 0.09, 2.01, 2.66 and 2.79 g. at 39°. H_2O exts. of flour and bran reduce the swelling of gluten in acids but not so markedly as neutral salts. Nonelectrolytes (cane sugar) have comparatively no effect except in high concns.

CHAS. A. ROUILLER.

Action of erepsin. FRANK E. RICE. *J. Am. Chem. Soc.* 37, 1319-33(1915).—Witte peptone was used as substrate, its hydrolysis being detd. by detg. the free amino N. The material contg. erepsin was prepd. by the Cohnheim method. The amt. of amino N split off from the peptone mol. by erepsin varies considerably with the initial concn. of the peptone soln. There seems to be no definite optimum degree of alkalinity for ereptic action, the addition of 1.7 to 4 cc. of 0.2 *N* NaOH per 60 cc. of digesting fluid accelerating the digestive action to about the same extent; more or less than these amts. of alkali diminish the activity; in R.'s expts. 2 cc. were used, this concn. of alkali producing no hydrolysis of the peptone. For about 10 hrs., the digestive action of erepsin is nearly proportional to the time, but after this there is less and less hydrolysis per unit of time. In studying digestions with varying amts. of erepsin,

enough concd. peptone soln. to contain 21 mg. of amino N, 2 cc. of 0.2 *N* NaOH, H₂O to 60 cc. and 8 drops toluene were digested 10 hrs. at 38°. The results obtained with erepsin from dog, horse, rabbit and cat intestines gave fairly const. values for $N/E^{3/4}$, where *N* is the amt. of amino N produced by *E*, the amt. of erepsin, provided there is no greater enzyme activity than would liberate more than 30 mg. of amino N under the given conditions. The value of the above ratio $\times 100$ (*N* and *E* expressed in mg.) is designated as the *ereptic power* of erepsin prepsns. Attempts to purify the erepsin prepsns. in various ways are described. Other things being equal, the longer the time of contact of the macerated mucous coat with the solvent, the more powerful are the erepsin solns. obtained; as a rule, however, very little is gained by prolonging the extn. more than 10 days. In very weakly alk. soln. (0.25 cc. of 0.2 *N* NaOH in 50 cc.) erepsin attacks conc. fibrin or fresh blood fibrin quite vigorously, but not when 1.5 cc. of NaOH is used. The action of erepsin on gelatin is very great. If the autolysis of the mucous coat of the small intestine can be measured by the amt. of amino N produced it takes place to the greatest extent in alk. soln. and where it takes place more actively more powerful erepsin prepsns. can be obtained. Erepsin prepsns. were generally preserved in 2 ways; the residue obtained from the pptn. of (NH₄)₂SO₄ is kept over H₂SO₄ in a desiccator, or a dialyzed neutral aq. soln. is kept at 10–5°; H₂O is better than dil. alc. When not enough preservative is present, there is very marked bacterial decompn., accompanied by the appearance of a tryptic enzyme.

CHAS. A. ROUILLER.

Digestive power of "pure pepsin." P. v. GRÜTZNER AND K. ZELLER. Tübingen. *Arch. ges. Physiol.* 161, 1–4 (1915); cf. *C. A.* 6, 2492.—A comparison of the digestive activity of pure pepsin (Pekelharing) and the extract of the pig stomach shows that the pepsin is from 20 to 30 times as active as the extract, as opposed to the earlier observations that the ext. was more active. The exts. of the stomachs of rabbits and cats are less active.

C. J. WEST.

Physiological activity of combined hydrochloric acid. J. H. LONG. *J. Am. Chem. Soc.* 37, 1333–47 (1915).—The digestive activity of HCl combined with certain NH₂ acids on the one hand and with complex proteins on the other was compared, digestion being measured by filtration and detn. of the sol. N in the filtrate, deducting, of course, the N furnished by the NH₂ acid and the pepsin. In this way, it was found that mixts. containing the coagulum from 1.5 g. egg albumen (1.06 g. protein), 15 mg. pepsin and amts. of betaine hydrochloride corresponding to 25, 50, 75, 100, 125 and 150 mg. HCl, made up to 60 cc. and digested 4 hrs. at 40°, gave amts. of sol. N corresponding to 0.3381, 0.3838, 0.7762, 0.9313, 0.9256, 0.9400 g., resp., of protein, while the values obtained with equiv. amts. of free HCl instead of the betaine salt were: —, 0.6125, 0.8887, 0.8812, 0.9538, 1.0112. The digestions with the free acid began somewhat earlier. The values obtained with fibrin (1.06 g. protein) and the betaine salt were: 0.2287, 0.8150, 0.9600, 0.9281, 0.9468, 0.9906. The salt evidently dissociates largely and that some of the HCl set free at once combines with the protein is indicated by the fact that when the coagulum from 1.5 g. egg powder is shaken 2 hrs. with 30 cc. of the salt soln. equiv. to 150 mg. HCl, filtered and washed with 30 cc. of H₂O, the filtrate requires 22.6 cc. of 0.1 *N* NaOH for neutralization with Me orange while the original salt soln. required 40.8 cc. The actual H ion concns. in betaine salt solns. of the above strength were found by potential measurements at 20° to be: 0.0085, 0.0135, 0.0176, 0.0220, 0.0256, 0.0292, while on the assumption that all the HCl was split off and completely dissociated the values would have been: 0.0114, 0.0228, 0.0343, 0.0456, 0.0571, 0.0686. Solns. (60 cc.) of the salt corresponding to 50 and 150 mg. HCl, allowed to stand 2 hrs. with frequent shaking with the coagulum from 1.5 g. egg and filtered, showed H ion concns. of 0.0055 and 0.0179, resp. Similar expts. with glutaminic acid hydrochloride gave 0.0625, 0.3254, 0.5769, —, 0.8051, 0.8244 g. for the amts.

d protein digested, and 0.0060, 0.0097, 0.0123, 0.0140, 0.0154, 0.0164, for the H ion concns. of salt solns. of the same strength; the lower H ion concns., as compared with those of the betaine salt solns., undoubtedly account for the lower digesting activity. An acid albumin prepd. by adding HCl to egg albumen, evapg. to dryness at a low temp. and adding more albumen powder to make the HCl content 5%, was found to be strongly acid in taste and only partly sol. in H_2O ; it contains 12.25% N, but when shaken with 50 parts H_2O and incubated 6 hrs. at 40° only about $\frac{1}{12}$ of the N is dissolved, and when 10 g. is shaken with 250 cc. H_2O and allowed to settle overnight and the filtrate is titrated, 100 mg. HCl is found with Me orange and 155 mg. with phenolph., showing that while some of the HCl dissolves in combination with the protein, about 20% of the original acid is present as free HCl. The H ion concn. of this filtrate is 0.00726, and when the treatment with 250 cc. H_2O is repeated 3 times, the H ion concns. of the successive solns. are 0.00517, 0.00483, 0.00352. In the presence of 50 mg. pepsin, about 60% of 2 g. of the above powder in 100 cc. H_2O digests in 6 hrs. at 40° but if increasing amts. of fibrin or egg albumen are added the digested fraction progressively diminishes, undoubtedly owing to the binding of the HCl. A series of expts. was carried out in which varying amts. of freshly coagulated egg albumen were digested in $N/15$ HCl, filtered and the filtrates titrated with Me orange, phenolph., HCHO and $AgNO_3$; H ion concns. were also detd. L. finds that in mixts. of protein and HCl the rate of digestion is slow when P_H is as low as 2.96 (e. g., when the wt. of the HCl is about 3.5% that of the egg albumen and 150 cc. of $N/15$ HCl is the liquid vol.) whereas when the wt. of the acid in 150 cc. of $N/15$ HCl is 10% that of the albumen ($P_H = 1.69$) digestion is very rapid. Dry preps. of protein and HCl about midway between these limits cease to be physiologically active.

B. METHODS AND APPARATUS.

STANLEY R. BÉNÉDICT.

The Sames procedure for the preparation of serums low in albumin. W. NEBEL. *Sonderabdr. Med. Klinik* 1913, No. 23; *Chem. Zig.* 38, Rept. 3(1914).—Fresh serums or serums freed from preservatives are dild., Na_2CO_3 and $(NH_4)_2CO_3$ added, and the mass heated to $50-60^\circ$. The subsequent addition of Al acetate with simultaneous acidification produces a ppt., sepg. about 50% of the albumin from the serum. J. S. G.

A method for the decomposition of the proteins of the thyroid, with a description of certain constituents. E. C. KENDALL. Rochester, Minn. *J. Biol. Chem.* 20, 501-9(1915).—Fat-free, desiccated thyroid is added to 90% EtOH containing 1% NaOH in the proportion of 2.5 g. thyroid to 100 cc. EtOH. The EtOH is boiled, with reflux, for 48 hrs. About 8% of the total N is given off as NH_3 . The hot EtOH soln. is filtered. The residue contains about 9% of the total N, 80% of the P and 7% of the I. H_2O is added to the soln. until the concn. of the EtOH is 75% and the NaOH is neutralized with H_2SO_4 . The soln. is cooled until the Na_2SO_4 seps. and is then filtered. The EtOH is distd. off. The NaOH may also be neutralized with CO_2 ; the EtOH is then distd. off directly. After all the EtOH has been evapg., the soln. is dild. to 100 cc. for each 20-25 g. of thyroid used and 20% H_2SO_4 added to complete pptn. After standing in the cold for several hrs., the ppt. is filtered and washed. This is fraction A. After drying *in vacuo* over H_2SO_4 and extn. with petr. ether, it is dissolved in dil. NaOH and repptd. with H_2SO_4 . By warming the soln. after addition of the acid to about 60° and then cooling it to 10° , the ppt. is obtained in a sandy, finely divided form which filters readily. It is fat-free and amounts to about 5% of the total amt. of thyroid taken. Its % content of I is about 10 times as high as that of the original material and the total recovered in this fraction is about 50% of the total I. By partial extn. with EtOAc, 2 fractions are obtained. The more sol. portion contains 13-14% I, while the less sol. fraction contains only 1.5% I. The filtrate from A is neutralized

with Na_2CO_3 , evapd. to small vol. and the Na_2SO_4 pptd. with EtOH. After filtration, the EtOH is evapd. and the soln., *B*, dried or preserved as such for therapeutic use. It contains about 74% of the total N. All the constituents are readily dialyzable. Satn. with $(\text{NH}_4)_2\text{SO}_4$ produces a ppt. containing about 80% of the I in *B*, showing that the I is in organic combination. The filtrate from the $(\text{NH}_4)_2\text{SO}_4$ ppt. contains a substance that reduces alk. Hg and Ag salts. This compd. is called *R*. The I in *B* is largely pptd. by HgSO_4 and almost quant. by Ag_2SO_4 and MgO . A large amt. is also split off in this treatment. After the administration of *B* to a patient with hypothyroidism, the dry scaly skin becomes moist and normal; soreness of bones and joints and heat flashes disappear. Muscle cramps are relieved and prevented by *R*. The administration of *B*, intravenously, subcutaneously or by mouth, failed to produce toxic symptoms. In hypothyroidism, the administration of *A* was followed by increase of pulse rate and rise of body temp. to the normal, increase of nitrogenous metabolism, and brightening of mentality. Daily subcutaneous injections of *A* in animals are followed in 2 or 3 days by an increase in pulse rate, nervousness, tremor, loss of wt. and diarrhea. The pulse rate soon drops suddenly and is not to be increased by further injections. The other symptoms persist and are similar to those of hyperthyroidism.

I. GREENWALD.

Colorimetric estimation of uric acid in urine. STANLEY R. BENEDICT AND ETHEL H. HITCHCOCK. Cornell Univ. Med. Coll. *J. Biol. Chem.* 20, 619-27(1915).—The method for the detn. of uric acid described by Folin and Denis (*C. A.* 7, 1523) is discussed and a modification proposed. The standard soln. of uric acid in Li_2CO_3 rapidly deteriorates and the value of the uric acid-HCHO standard is markedly affected by changes in the temp. A soln. in dil. pyridine is much more permanent but the best standard appears to be the following: 9 g. $\text{Na}_2\text{HPO}_4 \cdot 12 \text{H}_2\text{O}$ and 1 g. $\text{Na}_2\text{HPO}_4 \cdot \text{H}_2\text{O}$ are dissolved in 200-300 cc. hot H_2O , filtered and dild. to about 500 cc. This is poured upon 200 mg. of uric acid in a few cc. of H_2O in a liter flask. The mixt. is agitated until the uric acid dissolves and is then cooled. Exactly 1.4 cc. glacial HOAc are then added and the contents of the flask dild. to the mark. 5 cc. CHCl_3 are added as a preservative. This soln. keeps unaltered for at least 2 months. (Though the soln. is acid to litmus, no uric acid seps.) If 0.5 cc. more glacial HOAc be added, uric acid separates within a few hours. The following procedure is recommended by B. and H.: 2 to 4 cc. of urine (containing 0.7 to 1.3 mg. uric acid) are measured into a centrifuge tube, dild. to about 5 cc. and treated with 15-20 drops of a $\text{NH}_4\text{-Ag-Mg}$ soln. (This is prepd. by mixing 70 cc. 3% Ag-lactate, 30 cc. magnesia mixt. and 100 cc. conc. NH_4OH . The slight turbidity that forms shortly after mixing is filtered off. The clear filtrate keeps indefinitely. The magnesia mixt. is made by dissolving 17.5 g. cryst. MgSO_4 and 35 g. NH_4Cl in 100 H_2O , adding 60 cc. conc. NH_4OH and dilg. to 200 cc.) The contents of the tube are mixed with a small stirring rod and the tube is then centrifuged. The supernatant fluid is poured off as completely as possible, the drop on the inside of the lip being removed with a towel or filter paper. There are then added, in the order named, with stirring after each addition, 2 drops of 5% KCN soln., 0.5 to 1 cc. H_2O , 2 cc. of the reagent of Folin and Denis, and 10 cc. 20% Na_2CO_3 (anhydrous) soln. After 30 sec. the mixt. is washed into a 50 cc. vol. flask and dild. to the mark. The soln. for comparison in the colorimeter is prepd. at the same time by treating 5 cc. of the standard uric acid soln. with 2 drops 5% KCN, 2 cc. of the uric acid reagent, 10 cc. 20% Na_2CO_3 and dilg. to 50 cc. after 30 sec. The standard is best set at 15 mm. The KCN serves to dissolve the ppt. and neither the Ag nor the CN interferes with the reaction. The presence of the KCN intensifies the color obtained by about 18%. This is probably due to the marked diminution in the rate of fading of the color. This procedure gives quant. results with uric acid solns. and with uric acid added to urine.

The results agree within a few per cent with those obtained by the Folin-Shaffer method and is regarded as being as accurate as this, if not more so. I. GREENWALD.

Colorimetric estimation of uric acid in blood. STANLEY R. BENEDICT. *J. Biol. Chem.* 20, 629-40(1915).—In the Folin-Denis procedure for the detn. of uric acid in blood (cf. *C. A.* 7, 1214), the protein that escapes pptn. by simple heat coagulation interferes with the detn. The addition of colloidal Fe soln. removes this protein and if the method of Benedict and Hitchcock (cf. preceding abstr.) be then employed the resulting solns. are never turbid and good results are readily obtainable. The procedure recommended is: 20 cc. of blood are added to 100 cc. boiling 0.01 *N* HOAc in a casserole, the mixt. is heated to boiling, removed from the flame, dild. with 200 cc. boiling H_2O and filtered. The residue is washed with 50 cc. boiling H_2O (heated in the same casserole) and the total filtrate rapidly boiled down in a casserole to about 25 cc. This is then poured into a flask, roughly marked at 50 cc. and the casserole thoroughly washed 2-3 times with hot H_2O . The turbid liquid is cooled and 2 cc. (occasionally a little more) of colloidal Fe soln. (Merck's dialyzed Fe, 5% soln.) are added while rotating the flask. The mixt. is then filtered into a 100 cc. Jena-Florence flask and the residue washed twice with H_2O . The filtrate should be clear and colorless. It is boiled down to a vol. of 1-2 cc. and transferred to a centrifuge tube, the flask being washed 3 times with 1-2 cc. boiling H_2O . The contents of the tube are then cooled and pptd. and subsequently treated as described in the preceding abstr. If the bulk of the Ag ppt. is small, 1 cc. of the reagent and 5 cc. Na_2CO_3 soln. are used and the mixt. is dild. to 25 cc. I. GREENWALD.

The estimation of fat. HELMAN ROSENTHAL AND P. F. TROWBRIDGE. *Univ. Missouri. J. Biol. Chem.* 20, 711-7(1915).—The sample is heated for 2 hrs. at 100° with 30 cc. of 20% NaOH. (With samples rich in fat, use EtOH soln. With blood, ext. with boiling EtOH and saponify the ext.) Transfer to separatory funnel, acidify with 35 cc. HCl (sp. gr. 1.1), cool and shake out with Et_2O . Filter the combined exts. and evap. on water bath to dryness, dissolve in 25 cc. petroleum ether, add 10-15 cc. 95% EtOH and titrate with 0.05 *N* alkali, using phenolphthalein as indicator. [Factor is not given but appears to be 1 cc. = 14.50 mg. fat. ABSTR.] Method gives good duplicates. I. GREENWALD.

A simple hydrogen electrode. HENDRIK PIETER BARENDRECHT. *Delft. Biochem. J.* 9, 66-70(1915).—In an improved Walpole electrometric titrating apparatus (cf. *C. A.* 3, 1799) special provision is made for allowing instantaneous and accurate estimations even in liquids which contain CO_2 and O. B. HOROWITZ.

The cause and significance of an abnormal reaction obtained in testing urine for sugars with Fehling solution. W. CRAMER. *Edinburgh. Biochem. J.* 9, 71-7(1915).—A reduction of cupric salts to metallic Cu can be brought about by concd. aq. solns. of the reducing sugars. It takes place even more readily when the reducing sugar is present in a urine having a normal concn. of the normal urinary constituents, being facilitated by the fact that some of the constituents of normal urine, among them creatinine (see Maclean, *Biochem. J.* 2, 156(1907)), are capable of holding Cu_2O in soln. Such a reaction may indicate a marked glucosuria unaccompanied by polyuria, and not a typical diabetes mellitus. B. HOROWITZ.

Detection of small amounts of sugar by the production of formaldehyde and the formaldehyde-forming substances of the urine. E. SALKOWSKI. *Univ. Berlin. Z. physiol. Chem.* 93, 432-46(1915).—Two cc. of a 1% sugar soln., heated with 5 cc. of an oxidation mixt. containing 30 cc. dil. H_2SO_4 (200 g. to 1 l.), 20 cc. 1% $KMnO_4$ and 50 cc. H_2O , give a positive test for HCHO (Leach). A 0.2% soln. gives a positive test if 2 cc. of the oxidation mixt. are used. Two cc. urine, as above, give a strong positive

test. Attempts to ppt. the substances which give HCHO were fruitless. The $\text{Pb}(\text{OAc})_2$ ppt. may be washed free of these substances by $(\text{NH}_4)_2\text{CO}_3$ soln. 0.2% sugar in urine may be detected by pptg. a given vol. of urine with $\text{Pb}(\text{OAc})_2$, treating the filtrate with $\text{Pb}(\text{OAc})_2$ and NH_4OH , washing the ppt. carefully, dissolving in hot AcOH and making up to the original vol., and oxidizing 2 cc. of this with 5 cc. of the oxidizing mixt. Creatinine does not interfere with this test to any degree. G. M. MEYER.

Xanthydrol or the Fosse reagent in the determination of urea. HUGOUNENQ AND MOREL. *Bull. commercial; Giorn. farm. chim.* 63, 118-9(1914).—The authors recommend the use of xanthydrol for the detn. of urea in the blood and other liquids of the animal organism; a compd., dioxanthylurea, insol. in H_2O , is formed. The following procedure for the detn. of urea in blood is proposed: Take 10 cc. blood serum, add 100 cc. 95% alc., acidify slightly with AcOH , filter, and wash the coagulum twice with 95% alc. Evap. the alc. soln. to approx. 5 cc. on a H_2O bath and add 50 cc. of a 8-10% alc. soln. of xanthydrol and 50 cc. glacial AcOH to the residue. Allow to stand for a period of several hrs. (not to exceed 15), collect the ppt. of xanthylurea, wash with 95% alc., dry at 100° and weigh; this wt. divided by 7 gives the wt. of urea. Ten cc. of normal serum contain 15-30 mg. urea, while, in cases of azotemia, values exceeding 100 mg. urea per 10 cc. may be obtained. The use of xanthydrol in this procedure (also modified in technic by Fréjacque) is advantageous from the point of view of specificity, precision and rapidity. H. S. PAINE.

Precipitant for ammonia (GRAVES) 7. Centrifuge 1. Estimation of lead (MEILLÈRE) 7. The preparation of anhydrous solids (ATKINS) 2.

U. S., 1,137,388, Apr. 27. G. H. EARP-THOMAS. Container for preserving and transporting aerobic bacteria, such as N-fixing bacteria from legumes, consists of a stoppered bottle, with a glass tube extending straight down through the center of the stopper. The tube terminates centrally within the bottle in a narrow curved mouth and contains several sepd. plugs of cotton or other fibrous filtering material. Cf. C. A. 8, 2772.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The reducing properties of acetic bacteria. N. L. SÖHNGEN. *Folia mikrobiol.* 3, 4 pp.(1914); *Chem. Zentr.* 1915, I, 326.—The reducing action of acetic bacteria on organic compds. was studied. A yeast ext. containing organic compds. was used as medium. The aerobic reduction was studied with a thin layer of medium in the bottom of an Erlenmeyer flask. Under the surface the following processes take place: Glucose is oxidized to gluconic acid. Alc. and AcOH are formed. Aldehydes and ketones could not be detected. Under anaerobic conditions, glucose will decompose slightly to CO_2 and alc. Gluconic acid or its Ca salt in yeast ext. is decomposed by bacteria to dihydroxyacetone, CO_2 , H_2O and alc. In similar expts. with lactic, acetic, pyruvic and malic acids or the Ca salts, small amts. of alc. were formed when these acids were acted on by acetic bacteria. FRED W. TANNER.

The oxidation of hydrogen sulfide by bacteria. H. C. JACOBSEN. *Folia mikrobiol.* 3, 8 pp.(1914); *Chem. Zentr.* 1915, I, 324-5; cf. C. A. 8, 944.—J. describes an

app. in which oxidation of H_2S may take place. An Erlenmeyer flask is fitted by means of a rubber stopper with a bent glass tube and funnel. The culture medium is inoculated with 1-2 mg. of earth, etc., and incubated at 37° for 1-2 days until one is able to det. by the odor that the H_2S is completely oxidized. The second phase of the process, the oxidation to H_2SO_4 , requires a longer time. The process is quant. The energy needed by the bacteria comes from the oxidation processes. F. W. T.

The effect of shading on the transpiration and assimilation of the tobacco plant in Cuba. H. HASSELBRING. *Botan. Gaz.* 57, 257-86(1914); *Bull. Agr. Intelligence* 5, 1598-1600.—Plants grown in open ground transpired nearly 30% more than those grown under cheese cloth. The transpiration per unit area of leaf surface was nearly twice as great in the sun plants as in the shade plants. Shading did not seem to result in a diminished production of total plant substance by the shaded plants, as compared with other like plants not shaded. Owing to greater total area of leaf surface on the part of shaded plants, the quantity of plant material elaborated per unit of leaf area is greater in the plants grown in the open. While the total production of dry plant substance was not influenced in any marked degree by the shading, the distribution of this substance was affected to the extent that in shade grown plants relatively less material was deposited in the leaves and more in the stems than in the plants grown in open. No evident influence is exerted on the deposition of material in the roots.

Physiological studies on lactescence and caoutchouc. F. TOWLER. *Jahrb. Wiss. Botan.* 54, 265-307(1914).—Close relations were shown between quantity and quality of sap flow of *Manihot*, *Mascarenhasia*, etc., on the one hand, and stages of growth and such conditions as humidity, illumination, nutritive materials available, on the other. Secretions of the plants against snails were not proven. W. P. G.

Alfalfa laccase. H. H. BUNZEL. U. S. Dept. Agr. *J. Biol. Chem.* 20, 697-706 (1915).—"The effect of salts of strong bases with weak acids on the rate of oxidation of hydroquinone by atmospheric O is due entirely to the conc. of the OH ions in such solns. There is no hydroquinone-oxidizing oxidase 'laccase' in *Medicago sativa*. The accelerating effect of Euler and Bolin's 'laccase' prepd. from *M. sativa* on the rate of oxidation of hydroquinone by atmospheric O is due to the alkalinity of the solns. of the salts contained in their preps." Cf. *C. A.* 3, 1544, 2709; 4, 937; 8, 1971.

I. GREENWALD.

The value of the chemical factor in the study of plants. HENRY G. SMITH. *J. Proc. Roy. Soc. N. S. Wales* 48, 1-42(1914).—Presidential address. Emphasis is placed on the author's study of terpenes and related substances obtained from several species in the larger Australian genera.

B. HOROWITZ.

The relative chemotropic influence of salts of metals on radicles of *Lupinus albus*. T. M. PORODKO. *Ber. botan. Ges.* 32, 271-5(1914); *Exp. Sta. Rec.* 32, 128; cf. *C. A.* 8, 153.—All the salts tested gave negative tropism.

J. J. SKINNER.

Conditions of chemotropism in rootlets. T. M. PORODKO. *Ber. botan. Ges.* 32, 275-82(1914); *Exp. Sta. Rec.* 32, 128; cf. *C. A.* 8, 153.—The effect of the salts of metals on growth was studied. Both positive and negative tropism occur only with limited strengths of certain substances and chemotropic sensitivity is limited to about 1 to 2 mm. of the root tips.

J. J. SKINNER.

The protease of fruit juice. E. PANTANELLI. *Centr. Bakt. Parasitenk.* 42, 480-501(1914).—The juice of ripe wine grapes contains a proteolytic enzyme. The juice of unripe grapes does not contain it, but if the green fruit is allowed to stand for a long

while in the open air, the protease appears. This indicates the occurrence of a proenzyme in the unripe grapes. It comes down with the protein when pptd. The fruit protease can digest egg white but not fibrin and gelatin. It inhibits the action of pepsin and trypsin. The metabolic products of the cell life in grapes, as invert sugar and tartaric acid, inhibit the action of the protease and autolysis does not begin in grape juice until it is dild with H_2O . It takes place best in juice equiv. to 0.2 *N* acid. J. H. L.

Heat evolved in the germination of seeds. M. DARSIE, C. ELLIOT AND G. J. PEIRCE. *Botan. Gaz.* 58, 101-36(1914); *Bull. Agr. Intelligence* 5, 1432.—Using Dewar flasks, expts. made on barley, clover, maize, hemp, oats and wheat showed that the heat set free varied with the germinating power and the vigor. The older seeds evolved less heat. The av. daily increase of temp. produced by 10 g. of seeds in germination was 1.82° for hemp, 0.75° for clover, 0.73° for wheat, 0.55° for oats and 0.49° for maize. An abnormally high temp. denotes infection; an abnormally low, lessened vigor from old age.

M. X. SULLIVAN.

The formation of hydrocyanic acid in the germination of seeds. IV. CIRO RAVENNA. Univ. Bologna. *Atti accad. Lincei* 23, II, 302-6(1914); cf. C. A. 9, 1071.—The method of Bosshard (*Fittig's Jahresber.* 1883, 1608) for detg. NH_3 and Longi's modification (*Landwirt. Versuchsstat.* 29, 403(1883)) were tested out and found to give good results but they were somewhat lower than the calc. amt. The latter method consists in distilling the plant extracts with magnesia at reduced pressure and a temp. of 40°. Quantitative expts. on the seeds of *Phaseolus lunatus* in the quiet stage after 3 days, after 5 and after 7 days germination gave 0.015, 0.024, and 0.042% NH_3 by the latter method. The other methods gave almost identical results. As was stated previously *P. lunatus* is said to differ from other HCN-forming plants in that the HCN content diminishes up to the beginning of the germinative period. 31 analyses of seeds observed for 20 days in the dark and 36 days in the light are given. The HCN content increases during the 1st period of germination and then diminishes. *P. lunatus* is thus similar to other seeds in its behavior in this respect. E. J. WITZEMANN.

NORMAL.

A working hypothesis of hemoglobin pigment metabolism. T. ADDIS. San Francisco. *Arch. Intern. Med.* 15, 413-37(1915).—The following hypothesis of the course of hematin metabolism is presented. The hemoglobin liberated from outworn erythrocytes is sepd. into pigment and protein. Within the liver cells, the pigment is converted into bilirubin. In the intestine this is reduced to urobilinogen. This is absorbed, carried to the liver and, in part at least, utilized in the synthesis of hemoglobin.

I. GREENWALD.

Animal calorimetry. IX. The influence of meat ingestion on the amino acid content of blood and muscle. MARY WISHART. Cornell Med. Coll. *J. Biol. Chem.* 20, 535-7(1915).—"Although the ingestion of 1000 g. of meat may increase the amt. of amino acids (as expressed by "residual N" or difference between total non-protein N and urea N) and of urea in the circulating blood, yet in the muscles the quantity of amino acids may show no positive increase though the urea content of the muscles rises." It is concluded that amino acids absorbed by muscle are immediately destroyed or synthesized into new protein and that the specific dynamic action of protein is due not to the action of certain amino acids in increased conc. but to the action of certain metabolites of these amino acids. X. The rate at which ingested glycocoll and alanine are metabolized. FRANK A. CSONKA. *Ibid* 539-54.—Repeated phlorrhizination has no effect upon the character of the glucosuria induced. The ingestion of 2

g. of ext. of beef by the phlorhizinized dog has no influence on the output of glucose. The rate of absorption and elimination of ingested glucose by the phlorhizinized dog is almost the same as the rate of absorption of iso-glucogenic quantities of glycine or alanine and of the elimination of the glucose produced from them. The amt. of extra glucose elimination in phlorhizin glucosuria appears to be a better index of the intensity of the hourly metabolism of these amino acids when given to a normal dog than does the N output under these circumstances. In the phlorhizinized dog, the latter lags a little behind the glucose excretion. After giving Et lactate to a phlorhizinized dog only 40% of the glucose which could have arisen from the lactic acid appeared in the urine. **XI. An investigation into the causes of the specific dynamic action of the foodstuffs.** GRAHAM LUSK. *Ibid* 555-617.—All the expts. were performed upon dogs. After prolonged confinement in a cage, though without loss of body wt., a dog may manifest a marked reduction in basal metabolism. Recovery is apparently achieved through exercise. Ingestion of a cold liquid causes an abstraction of heat for the purpose of warming it. With 210 cc. of H₂O or of a glucose soln. this is not entirely accomplished in 1 hr. and therefore causes a discrepancy in the measurement of heat by the direct and indirect methods, in expts. begun 1 hr. after such ingestion. This explains the disparity noted in a previous paper (cf. C. A. 7, 107). The explanation then given is withdrawn. The administration of glycine or of alanine increases the metabolism. If both are administered together, there is complete summation of their effects. The extra heat production after giving glycine is nearly equal to the energy content of the glycine; with alanine, it is only 53% of the energy content of the alanine. The quantity of extra heat is not proportional to the amt. of glucose that may be formed from glycine or alanine but is apparently the same for 1 mol. of glycine as for 1 of alanine. When carbohydrate is transformed into fat there is a small elimination of heat, for which allowance can be made. The administration of glucose with either glycine or alanine produces an increase in metabolism almost as great as the sum of the increases due to the two given separately. (This nullifies the opinion previously expressed (cf. C. A. 7, 363).) The influence of the metabolites of carbohydrates upon metabolism is much less than that of the metabolites of iso-glucogenetic amts. of glycine or alanine. The influence upon heat production of 50 g. of glucose, sucrose and fructose increases in the order named. After giving 50 g. of lactose there was no, and after 50 g. of galactose very little, increase in metabolism or in the respiratory quotient. A part of these sugars appeared in the urine. Ethyl glycolate is poisonous. Small amts. of EtOH (5.8 and 9.4 g.) increase metabolism and do not merely replace isodynamic quantities of fat. The effect on heat production of glucose and EtOH ingested together is nearly equivalent to the sum of the increases produced by each alone. The lactic acid from the administration of Et lactate probably increases metabolism. The administration of phlorhizin may increase metabolism as much as 70% above its basal value. Glucose or fructose given to phlorhizinized dogs does not increase the metabolism. The administration of glycine or of alanine under the same conditions does increase metabolism, although their energy content is eliminated in the urine in the form of glucose and urea. Since amino acids absorbed by muscle are immediately catabolized or synthesized into new protein (cf. Wishart, above) and since the period of max. heat production almost coincides with the period of max. metabolism of amino acids (the increase in metabolism may outlast the stimulus), L. concludes that not the amino acids themselves but certain intermediate products, such as glycollic or lactic acids, provide the stimulus. The specific dynamic action of protein is thus considered to be due to the action of the metabolites of certain of the amino acids in the protein. "Since metabolism in human diabetes is increased only 5 or 10% in the presence of severe acidosis, while the metabolism in depancreatized dogs is increased 40% when acidosis is only

slightly above the normal, and by 70% during the very mild acidosis of phlorhizin glucosuria, it is evident that the increase in metabolism in the diabetic state is in no way proportional to the intensity of the acidosis, and hence the acidosis cannot be the etiological factor of the increased metabolism. A much more plausible explanation lies in the 3- to 5-fold increase above the normal in the quantity of amino acids metabolized in phlorhizin glucosuria, although there may be still other contributing factors."

I. GREENWALD.

Nutrition with purified food substances. E. V. MCCOLLUM AND MARGUERITE DAVIS. Univ. Wisc. *J. Biol. Chem.* 20, 641-58(1915).—See preceding papers by McCollum and Davis (*C. A.* 7, 3354; 8, 3673; 9, 1497) and by Osborne and Mendel (*C. A.* 7, 107, 364, 635, 3355; 8, 730, 1978, 2561, 2565, 3318; 9, 1497). Rats were kept on a diet of pure casein, dextrin (prepd. in lab.), lactose, agar-agar and reagent salts, with and without certain additions. The rats ate a certain amt. of wood (from the cages) but this is considered unobjectionable since the fragments of wood did not appear to disintegrate. The above diet was incomplete, the rats growing for about 6 months, then rapidly losing wt. Addition of 5% of olive oil did not prolong the growth period but addition of 5% of butter fat or of 3% of the ether ext. of cod testicle or of pig kidney maintained normal growth. On the diet containing butter, rats gave birth to 2 and 3 litters of young, some of which have been kept for a long time on the same diet as the mother. The expts. of Osborne and Mendel in which natural "protein-free" milk was used are criticized. Such preps. contain 0.7% N, which, though not protein, may very well be present as products of protein hydrolysis, for there are proteolytic enzymes in milk. Such "split-products" would be as efficient as milk proteins in maintaining growth. Expts. by McC. and D. indicate that the N of "protein-free" milk is nearly, if not quite, as effective as the N of milk protein in maintaining body wt. If the N of "protein-free" milk is derived from protein, it is equivalent to a content of 4.37% protein in the prep. Of this, Osborne and Mendel used 28% in their diets; that is, 1.22% of the diet might consist of "split-products" from milk protein. McC. and D. have shown (cf. *C. A.* 9, 1497) that a content of 3% of milk protein as the sole protein in the diet serves to maintain rats in body wt. In other words, over 0.33 of the maintenance requirement of milk protein may have been present in the "protein-free" milk used by Osborne and Mendel. .

I. GREENWALD.

Cholesterol content of the tissues of growing rats when under various diets. PERCY E. LANDER. London. *Biochem. J.* 9, 78-96(1915).—No growth occurs when rats are fed on a pure synthetic diet containing no cholesterol, the content of the latter in the tissues showing neither an increase nor decrease. The replacement of half of the pure caseinogen used in the synthetic diet by cholesterol-free protein obtained from bull testicles, to which lecithin is added, gives a similar result. If 20 cc. milk *per diem* is added to the synthetic diet the rats increase in weight by 66% in 23 days. The quantity of cholesterol found in the organism can be accounted for by that contained in the milk: there is no evidence of any synthesis. By giving only 10 cc. milk, and in addition 2% cholesterol, growth is much less during 23 days. About 0.1 of the cholesterol ingested is stored. The addition of cholesterol and cholesterol esters to a synthetic diet, together with lecithin and lemco, does not cause growth. A diet of bread and oatmeal which had been imperfectly extd. with ether, together with 2% cholesterol, produces slight growth. The expts. do not show that cholesterol can be manufactured by the living organism.

B. HOROWITZ.

Energy requirement of newborn. H. C. BAILEY AND J. R. MURLIN. New York. *Am. J. Obstetrics and Dis. of Women and Children* 71, No. 3(1915); *J. Am. Med. Assoc.* 64, 1272-3; cf. *C. A.* 9, 1191.—The analyses reported show that human colostrum on the 2nd and 3rd days of the puerperium has the following comp.: Protein 2.3, fat 2.9,

milk sugar 7.1%, making a physiologic heat value of 650 cal. per liter. It is not until the 5th day that there is sufficient breast secretion to supply the requirement of the newborn for combustion alone, ignoring growth. Studies by the authors show that supplementary feeding of newborn infants from the 1st day onward with food somewhat resembling colostrum in comp., diminishes the initial loss of wt., accelerates the return to birth wt., and has no unfavorable effects. The respiratory quotients of 2 infants 6 hrs. old indicate that the child at birth has some carbohydrate available for combustion. By the end of the first 24 hrs. this supply is exhausted and the child has reached a pure fat combustion. If food is not supplied soon after this a starvation acidosis is likely to develop. The energy requirement of the newborn when comfortably warm and sleeping is from 1.7 to 2.0 per kg. an hr., the lower figure being for a fat child and the higher for a thin child. Vigorous crying does not raise these figures more than 40%.

L. W. RIGGS.

Gastrointestinal studies. VII. The utilization of ingested protein as influenced by undermastication (bolting) and overmastication (fletcherizing). L. F. FOSTER AND P. B. HAWK. *J. Am. Chem. Soc.* 37, 1347-61 (1915).—The expts. were conducted upon 2 lab. assistants, 22 and 24 yrs. old, weighing 58.3 and 63 kg., resp., and were divided into a preliminary normal period of 3 days, a bolting period of 7 days in which the meat was swallowed without mastication, a period of 7 days in which the food was chewed thoroughly (fletcherized) and a final normal period of 7 days. A uniform diet, with 16.603 and 19.184 g. N, was fed throughout to the 2 resp. subjects; the major portion of the protein (11.207 and 13.025 g. N) was in the form of meat (round steak freed from all visible fat and connective tissue). During the bolting period, macroscopic meat residues in the stools were separately analyzed for N. Both subjects worked hard on research problems during the expts. and every day took a brisk 2.5 mile walk or a 20 min. swim. The av. daily fecal N outputs of the 2 subjects for the 4 periods were: 0.759, 1.306; 0.948, 1.266; 0.726, 0.906; 0.765, 0.919 g.; % utilizations: 95.43, 93.19; 94.29, 93.41; 95.63, 95.32; 95.39, 95.21. Every stool during the bolting period contained macroscopic meat residues. Av. daily N excretions in the urine: 16.369, 18.827; 16.229, 17.990; 16.697, 20.118; 16.639, 19.703. The method of Mendel and Fine (C. A. 6, 879) was used to det. the portion of the total fecal N due to metabolic products; at the close of the final period, a N-free diet of equal calorific value to that previously ingested (consisting of butter, sugar, agar-agar, H₂O and NaCl) was chosen, the feces analyzed for total N, corrections applied for the N of the unutilized butter, carmine (used to sep. the feces of the different periods) and a gelatin capsule and the resultant value subtracted from the av. daily N output of each period. The difference was assumed to be the N due to unabsorbed residues of meat. The av. daily N content of the feces of the 2 subjects was 0.500 and 0.552 g. but this value is doubtless too high, especially in the 1st case, as the vol. of the feces during this period was much greater than in the other periods and an increase in metabolic N would be expected with an increase in bulk of the material in the intestine. By calcg. the metabolic N for the other periods on the tacit assumption that the content is proportional to the vol. of the feces, these values become 0.268 and 0.432 g. These are probably too low, but the actual output undoubtedly lies between the 2 limits. The lower values were applied as corrections to the above % utilizations and more accurate data thus obtained. F. and H. conclude that their work does not support the claims of Fletcher and his followers and does not demonstrate the harmfulness of food-bolting to the organism.

CHAS. A. ROULLER.

Research on the transformation of energy in the domestic fowl. H. GERHARTZ. *Landw. Jahrb.* 46, 797-814 (1914); *Bull. Agr. Intelligence* 5, 1623; cf. C. A. 8, 1968. —The transformation of energy in fasting fowls is less than in normally fed ones. The

formation of the egg in the hen is accompanied by a considerable expenditure of energy. For other details and conclusion see original article.

J. J. SKINNER.

Net energy values of feeding stuffs for cattle. H. P. ARMSBY AND J. A. FRIES. *J. Agr. Res.* 3, 435-91(1915).—There are reported the results of 76 expts. in the respiratory calorimeter upon 9 steers in which the balance of matter and of energy was detd. The losses of energy from the animals are of 2 classes: (1) Losses of unused chem. energy in the feces, urine and methane; and (2) losses in the form of heat due to increased metabolism consequent upon the ingestion of feed. The losses of energy in methane and urine were relatively greater on light than on moderately heavy rations. Neither the losses of energy in the feces nor the total losses showed a distinct relation to the amt. of feed consumed. Individual differences between animals had no material influence on the losses of chem. energy. Energy loss in methane may be computed approx. from the amt. of total carbohydrates digested. The metabolizable energy per kg. of digested org. matter showed but slight variations within the same class of feeding stuffs. The heat production is notably greater during standing than during lying, and the difference is greater on heavy than on light rations. The increment of heat production during standing is affected by the individuality of the animal and the kind of feed. The av. energy expenditure consequent upon the consumption of 1 kg. of dry matter is reported for 11 diff. feeding stuffs. The expenditure of energy arising from the consumption of the coarse feeds is not on the whole much greater than in the case of the concentrates. The increased muscular work of the digestive organs appears to be a relatively small factor of the increased heat production. A scrub steer showed a somewhat greater increment of metabolism from feed consumption than did a pure-bred beef animal. A summary of the av. net energy values obtained in the expts. for 11 diff. feeding stuffs is given. A simple method is outlined for computing net energy values, in the absence of direct detns., from metabolism expts. or from the data of ordinary feeding tables.

M. X. SULLIVAN.

Studies in uric acid metabolism. I. The uric acid in ox and in chicken blood. STANLEY R. BENEDICT. Cornell Univ. Med. Coll. *J. Biol. Chem.* 20, 633-40(1915); cf. Benedict and Hitchcock (*C. A.* 9, 1626).—It was found that if the pptn. with $\text{NH}_4\text{-Ag-Mg}$ soln. was omitted in the detn. of uric acid in ox blood very high values were obtained (4 mg. per 100 cc. or 800% of that obtained in the usual detns.). In chicken blood the excess was only 20%. Upon investigation, the difference was found to be due to the presence in ox blood of a combined form of uric acid. This combination is quite stable and, apparently, cannot be hydrolyzed with HCl without at the same time destroying some of the uric acid. The uric acid is slowly liberated spontaneously when the blood is allowed to stand. The addition of 2 cc. of conc. HCl before the concn. results in the yield of at least 90% of the value obtained by an estn. of the "free" uric acid after the blood has been allowed to stand 2 weeks. Three attempts to isolate the uric acid, as such, from 100 cc. of ox blood were all successful. From one specimen giving by analysis 7.0 mg. of "total" uric acid per 100 cc. there were isolated 6.7 mg. of uric acid, identified by cryst. appearance, solubility, murexide test, colorimetric value and N content. In ox blood the uric acid, both "free" and "combined," is present exclusively in the cells; in chicken blood, on the other hand, the uric acid is found entirely, or nearly so, in the serum.

I. GREENWALD.

ABNORMAL.

Karamose (Merck) for diabetics and children. F. UMBER. *Deut. med. Wochschr.* 41, 181-2(1915).—Karamose (Merck) is caramelized glucose containing but traces of the original sugar. It can be given in various forms and is tolerated well in doses of 100 g. *per diem*, whereby 90% or more is resorbed. Larger doses are likely to cause diarrhea. One g. water-free karamose yields 4.3-4.5 cal. In lighter cases of diabetes

it does not increase the excretion of sugar in the urine, but acts as a protein-sparing agent. It may be of value in severe cases of diabetes, although under these conditions it may lead to increase of sugar excretion. In severe cases with acidosis it does not seem to counteract the latter. In children 5 g. proved to be a good laxative. S. A.

Studies of the basal metabolism in obesity and pituitary disease. J. H. MEANS. Harvard Univ. *J. Med. Res.* 32, 121-58(1915).—Basal metabolism, body surface (by Meeh's and by Dubois' formulas), and creatinine detns. are given in 2 cases of simple obesity, 2 cases of obesity in hypopituitarism, and 1 case of acromegaly. It was found that estns. of the body surface by Meeh's formula might be 30% (or more) higher than Dubois' in obese persons. The Dubois formula is unquestionably the more accurate. The basal metabolism in the 2 cases of simple obesity per sq. m. and hr. using the Dubois area was normal. In 1 case of undoubted hypopituitarism there was increased basal metabolism; in 2 other cases thought to be hypopituitary, 1 with a low and 1 with a high sugar tolerance, both showed a low metabolism. The creatinine coeff. is lower than normal in all the cases studied. The administration of thyroid ext. in a case of simple obesity gave an increase in the basal metabolism, this increase being met by an increased katabolism of protein, but more particularly of carbohydrate and not at all by fat. Apparently thyroid increased the utilization of carbohydrate, which is burned instead of being stored as fat.

GEO. T. CALDWELL.

Metabolism study of a case of congenital hemolytic jaundice with splenomegaly. JAMES P. MCKELVEY AND JACOB ROSENBLOOM. Pittsburgh. *Arch. Intern. Med.* 15, 227-38(1915).—A metabolism expt. of 5 days, during which there was a loss of N, S, Ca, Mg, and Fe and slight retention of P, disclosed a normal N partition in the urine, except for a rather high uric acid excretion. The absorption of N was normal. The S partition was normal, except for a high ethereal sulfate excretion on the first and last days. The loss of Fe was pronounced. Fat metabolism was normal. Urobilin and urobilinogen were present in urine and feces; bilirubin and hemoglobin were absent. Cf. C. A. 9, 933.

I. GREENWALD.

Prevention of beriberi among "Philippine scouts" by means of modifications in the diet. WESTON P. CHAMBERLAIN. U. S. Army. *J. Am. Med. Assoc.* 64, 1215-20(1915); cf. C. A. 5, 3484.—On a diet consisting of 12 oz. of fresh beef or its equiv. in bacon, canned meat or fish, 20 oz. of polished rice, 8 oz. of flour or bread, 8 oz. of potatoes or onions, and the usual condiments, the cases of beriberi reached a total in the years 1908 and 1909 of 618 and 558, respectively, in a force of about 5200 men. In 1910 the dietary was changed by a reduction of the rice to 16 oz. and using the undermilled or unpolished variety, and the introduction of 8 oz. of camotes (similar to sweet potatoes), and 4 oz. of mongos (a kind of beans), when the cases of beriberi dropped to 50. In 1911 the ration was further modified by the compulsory consumption of 1.6 oz. of ordinary navy beans, for which mongos could be substituted, and the omission of camotes. In the years 1911 to June 1914 but 6 cases of the disease occurred. From C.'s observations it appears that the daily consumption of 1.6 oz. of beans with not more than 16 oz. of polished rice, or 16 oz. of unpolished rice without the beans, are sufficient to prevent neuritis. Many articles of diet other than rice are relatively deficient in neuritis-preventing vitamins, and these vitamins may be decomposed by exposing food to temps. above a certain point.

F. PHYSIOLOGY.

ANDREW HUNTER.

The urea content of the human spinal fluid and blood. G. E. CULLEN AND A. W. M. ELLIS. Rockefeller Inst. *J. Biol. Chem.* 20, 511-2(1915).—Urea was detd. in spinal fluid and in blood taken from the same patient within a few min. of each other.

The values found were from 20 to 42 and from 22 to 46 mg. of urea per 100 cc. of spinal fluid and blood, resp. In 63% of the cases, the difference between the urea content of the blood and of the spinal fluid was less than 2 mg. per 100 cc. The greatest difference was 11 mg. per 100 cc. Such occasional differences are probably due to the rapid rise and fall of the urea content of the blood in different stages of protein digestion. The urea content of the spinal fluid probably lags a little behind this. I. GREENWALD.

Presence of iodine in the human fetal thyroid gland. FREDERIC FENGER. *J. Biol. Chem.* 20, 695-6(1915).—Both enlarged and normal sized human fetal thyroids contain I at least during the last three months of intra-uterine life. Normal sized fetal glands contain relatively more I and less P than enlarged fetal glands. These conditions are analogous to those existing in the fetal and adult thyroids from cattle, hogs and sheep. (Cf. *C. A.* 7, 2241.) I. GREENWALD.

Gastric digestibility of milk. E. FILIPPI. Florence. *Lo sper.* 72, 203-30; *Zentr. Biochem. Biophys.* 17, 432(1914).—F. has studied the effect of colloids on the activity of rennin and has attempted to ascertain whether the ingestion of foreign substances as an aid to the digestion of milk is advisable in view of the fact that the voluminous coagulum which is produced on the entrance of milk into the stomach contributes to gastric affections which are characterized by deficiency of pepsin. Numerous viscosimetric measurements indicated that coffee (as an infusion) is the only common substance which is capable of preventing the coagulation of milk by rennin and which at the same time is harmless to the organism and is also not repugnant (as are albumin, gum and starch); coffee infusion inhibits peptic digestion, however, as well as coagulation by rennin. Tea retards rennin coagulation to a less extent than coffee, but has the advantage of promoting the peptic digestion of casein. The latter action experiences a slight retardation in a pronounced viscous medium; when the colloid conc. is decreased an optimum is reached at which digestion is again retarded. H. S. PAINE.

Behavior of the interstitial cells of the testicle in general affections of the organism and their content of fats and lipoids. CARLO GAMNA. Turin. *Arch. sci. med.* 37, 443-79; *Zentr. Biochem. Biophys.* 17, 442-3(1914).—G. investigated the fat of the interstitial cells by means of various microchem. methods and found that fatty substances were constantly present as products of physiol. metabolism. These substances consisted of true fats and lipoids, the greater portion of the former being neutral fats of various kinds. The lipoids in the interstitial cells of the testicle were usually present in the form of solid granules; less often they were present as the result of general inhibition. These lipoids were generally diminished in acute febrile affections.

H. S. PAINE.

Cultivation of human tissue in vitro. J. R. LOSEE AND A. H. EBELING. Brooklyn. *Bul. Lying in Hospital, N. Y. City* 10, No. 1(1915); *J. Am. Med. Assoc.* 64, 1273.—A strain of human connective tissue was kept in a condition of active life *in vitro* for more than 2 months. The culture medium consisted of human blood plasma, ext. of adult or fetal tissues and Ringer soln. L. W. RIGGS.

Effect of various procedures on the passage of liquids from the stomach. C. H. NELSON AND S. T. LIPSITZ. St. Louis. *J. Am. Med. Assoc.* 64, 1052-5(1915).—Expts. with healthy young men show that water is emptied from the stomach more rapidly during exercise than when the subject remains quiet. Lying on the right side causes a more rapid evacuation than in any other position, and lying on the left side has the opposite effect. Lying on the back causes a more rapid emptying than in the upright position. Water taken at 45° leaves the stomach more rapidly than if taken at 10°. Normal acidity causes a more rapid emptying than hyperacidity produced artificially by adding HCl to the stomach contents. Artificial alkalinity produced

by adding NaHCO_3 to the stomach contents causes the stomach to empty slightly less rapidly than under normal conditions, but more so than during hyperacidity.

L. W. RIGGS.

Uric acid content of the blood of children. E. LIEFMANN. Dresden. *Z. Kinderheilk.* 12, 227-38(1915).—The blood of normal infants, fed with a purine-free diet, contains 1.3-1.7 mg. uric acid per 100 cc. In the growing child this slowly increases until it reaches the well-known value of 2-4 mg. for adults. With diets containing purine the value increases rapidly and then decreases slowly to the normal. High uric acid values indicate severe general disturbances of the organism. Atophan causes a decrease and protoioduret an increase in the uric acid content of the blood. The uric acid content of the blood in different diseases was studied. C. J. WEST.

Chemical and physico-chemical properties of muscles and muscle juice. V. The water, extractive nitrogen and total nitrogen content of white and red striated muscles. G. QUAGLIARIELLO. Univ. Naples. *Atti accad. Lincei* 23, II, 634-8 (1914).—The animals used were the turkey cock (*Meleagris gallopavo*), the domestic cock (*Gallus gallorum*) and the rabbit (*Lepus cuniculus*). The dry residue and total and extractive N of both kinds of muscle were detd. The general conclusions from the analytical data (cf. tables in the original) are: (1) The dry residue of white muscles in birds is constantly and appreciably greater than in the red muscles; in the rabbit they are nearly equal. This result is in harmony with the results of Costantino (*C. A.* 6, 390). (2) The total N content of white muscles is constantly higher than that of red muscles either in birds or in the rabbit; the difference seems greater in rabbits. This difference in the N appears whether the N is referred to the fresh muscle or to the dry residue. (3) The extractive N in the birds and rabbit is more abundant in the white muscles than in the red; this difference exists not only in the absolute values of the extractive N referred to the fresh muscle or to the dry residue but persists when the values are referred to the total N. These results are in agreement with those of Rinaldi (*C. A.* 6, 2450) and Cabella (*C. A.* 7, 2241). The extractive N of white or red muscles of rabbit considered either in abs. values or in relation to the total N, exceed that contained in the corresponding muscles in the birds. E. J. WITZEMANN.

Human milk. ALFRED W. BOSWORTH. *J. Biol. Chem.* 20, 707-9(1915).—The following arrangement is offered as representing the probable condition in which the constituents are present in human milk of av. comp. In %: fat 3.30, milk sugar 6.50, proteins combined with Ca 1.50, CaCl_2 0.059, KH_2PO_4 0.069, Na citrate 0.055, K citrate 0.103, $\text{MgH}_2\text{P}_2\text{O}_7$ 0.027. (Cf. Van Slyke and Bosworth, *C. A.* 9, 1068). J. G.

Lipase studies. I. The ester-splitting faculty of normal tissues. C. QUINAN. *J. Med. Res.* 32, 45-71(1915).—Ester-splitting, lipolytic enzymes are contained in the liver, kidney and muscle tissue of normal guinea pigs. The enzyme conc. per g. of tissue is characteristic of and const. for each organ. The conc. of the 3 tissues, liver, kidneys and muscle, in terms of ethyl butyrate per unit of tissue in unit of time, may be expressed by the respective numbers 44.3, 25.5 and 13.5. It is suggested that the relationship between these tissues may be proportional to their cellularity. Chlorides, CHCl_3 , fresh bile and Na glycocholate exert an inhibiting action on these tissues *in vitro*. Na acetate accelerates the hydrolysis of ethyl butyrate by the lipolytic enzymes of these tissues. It is probably the same enzyme which is present in all these tissues. II. Experimental chloroform necrosis of the liver. *Ibid* 73-93. CHCl_3 induces central necrosis of the liver in guinea pigs. The morphological change known as necrosis is preceded by a loss of the lipolytic enzyme, which loss may amt. to nearly 38%. The figures for the lipolytic activity of both the kidney and muscle tissue show at the same time, a corresponding increase. CHCl_3 intoxication does not affect the autolytic activity of the liver cells. GEO. T. CALDWELL.

G. PATHOLOGY.

H. G. WELLS.

A peculiar case of anaphylaxis to fly sting. WEBER. *Münch. med. Wochschr.* 62, 151 (1915).—A non-alcoholic, apparently healthy, 40 years old man was stung on the finger by a fly, probably *Haematopta pluvialis* Linn. Following the sting he became dizzy and was brought to the hospital cyanotic, dyspneic and nearly pulseless. The patient recovered slowly during the next 24 hrs. Two days after the sting there was an urticular bleb on the finger. Six years previously he had a similar attack after a sting through the glove. S. AMBERG.

Rapid intoxication of rabbits by certain bacterial products. W. J. PENFOLD AND H. VIOLLE. *Ann. inst. Pasteur* 28, 930-42 (1914); cf. *C. A.* 8, 1824.—Rabbits are sensitized to certain bacterial products by the injection of amts. of distd. H_2O equal to 1-30 of the body wt. of the animal. This sensitization was observed equally with cholera organisms and cholera toxin when all the living organisms were excluded. In either case the reaction is acute and death may follow immediately. This sudden death occurs equally if the culture or the cholera toxin has been given first and the distd. H_2O afterward. The cholera toxin may be injected by other than the intravenous route. A previous injection of conc. saline soln. has only a slight effect in counteracting this intoxication. The augmentation of the toxic effect by the addition of dist. H_2O was observed also with *Proteus vulgaris*, *B. pyocyaneus*, *B. dysenteriae* (Shiga), *B. prodigiosus* and also, but feebly, with tuberculin; it was not observed with mineral poisons such as HCN, and the alkaloids such as strychnine. The injection of a small quantity of hemolyzed blood and a sub-lethal dose of cholera culture produced acute death. The lysis of the red blood cells seemed to be the most important factor in producing this effect. The authors propose the name "toxohematolysis" for this phenomenon produced by the coördination of the 2 factors. GEO. T. CALDWELL.

Studies in anaphylaxis. XIII. The activation of antibody by the cell. RICHARD WELLS. New York. *J. Med. Res.* 32, 107-20 (1915).—When a guinea pig is passively sensitized by the action of an alien immune serum (rabbit versus horse serum), two separate and distinct processes take place. First, the body cells appropriate and anchor the immune body, abstracting it from the circulating blood. Second, the body cells produce an alteration, or activation, of the anchored antibody. This activation consists (1) in a very much increased avidity of the antibody for antigen, and (2) in the acquired property of inducing a physiological cellular response (such as muscular contraction in the case of the uterus) when the intracellular antibody is brought into contact with antigen. These changes occupy the so-called "latent period" of passive sensitization. During the latent period the anchored antibody can react with antigen, but the reaction induces no muscular contraction. When the cells have activated the anchored antibody, the latent period is concluded, and a muscular contraction characterizes the reaction of uterine antibody with antigen. Cellular activation of antibody is therefore the basis of the anaphylactic reaction. The anchored antibody differs from circulating antibody in the possession of an increased avidity for antigen; moreover, it has the property of inducing a cellular response upon uniting with antigen, a feature which is entirely lacking in the circulating antibody. Thus, the cell lends peculiar, and essential, characteristics to its antibody in active, as in passive, anaphylaxis. GEO. T. CALDWELL.

The relation between amylase retention and excretion and non-protein nitrogen retention in experimental uranium nephritis. R. FRIZ. Boston. *Arch. Intern. Med.* 15, 524-42 (1915).—In acute U nephritis in rabbits there is an accumulation of non-protein N in the blood and a diminished amt. of amylase in the urine. As the kidney recovers, both return to the normal amt. The amylase test, like the phenolsulfone-

phthalein test, indicates the renal function at the time; the amt. of non-protein N in the blood is influenced by the duration of the condition. The amylase test is less satisfactory than the phenolsulfonephthalein test.

I. GREENWALD.

Further studies of renal function in renal, cardiorenal and cardiac diseases. I. G. ROWNTREE, E. K. MARSHALL, JR. AND W. A. BAETJER. Johns Hopkins Univ. *Arch. Intern. Med.* 15, 543-54(1915).—The estn. of diastatic activity in the urine showed low values in the majority of cases of nephritis, while in cardiac and cardiorenal cases the results were very irregular. Normal values were frequently found in cases in which there was considerable, or even grave, renal functional involvement. Also, low values were obtained in cases in which, judged by the clinical aspect and by other functional tests, the renal function was not seriously impaired. The test has, therefore, little diagnostic or prognostic value. The detn. of the amt. of non-protein N or of urea in the blood appears to be more valuable than a detn. of the depression of the f. p., since it was found that the latter was lacking in several instances in which there was definite N retention. The phenolsulfonephthalein test is the most valuable single test. If the excretion is decreased, though only slightly, the non-protein N or urea of the blood should also be detd.

I. GREENWALD.

Studies in pancreatic disease. I. Duodenal content analyses as an index of disease and functional activity of the pancreas. II. Observations on fat and nitrogen metabolism in diseases of the pancreas. BURRELL B. CROHN. Mt. Sinai Hosp., New York. *Arch. Intern. Med.* 15, 581-607(1915).—Diminution in the enzymic activity of the duodenal contents is a reliable indication of organic disease of the pancreas. Only rarely does a diminution occur as a symptom of advanced organic disease elsewhere. The absorption of fat and of N appears to be independent of the character of the secretion of the pancreas. Absorption tests indicate the functional activity of the gland, not its organic condition.

I. GREENWALD.

Investigation of the blood enzymes in the albumin and globulin fractions of the serum. G. SATTA. Torino. *Arch. sci. med.* 39, 46-50(1915).—The albumin fraction contains all the tributyrinase, amylase, and glycyl-L-tyrosinase. The enzymes thus show a marked difference from complement, which may be divided between the 2 protein fractions.

M. HEIDELBERGER.

The excretion of antigen. AGNES E. PORTER. London. *Biochem. J.* 9, 1-8 (1915).—Egg white introduced parenterally into a rabbit is excreted unchanged in chem. properties, but may be in three possible variations as regards specificity: (1) It may retain partial properties as antigen, binding complement in the presence of anti-egg serum, not causing pptn. but capable of exercising an influence over an antibody so as to prevent it pptg. with fresh antigen; (2) it may be excreted in a non-specific form completely indifferent as antigen; (3) it may retain full antigen properties. This variation in specificity of excreted albumin points to a physical rather than a chem. explanation of the precipitin reaction.

B. H.

Experiences with the Abderhalden reaction. EBELER AND LOHNBERG. *Berl. klin. Wochschr.* 52, 319-21(1915).—Twelve normal women failed to give a positive Abderhalden reaction with placental tissue. Of 11 cases of extra-uterine pregnancy, 6 gave a positive reaction and 5 a negative reaction. In 39 cases of normal pregnancy, only 1 did not give the reaction; in 61 gynecologic cases, without pregnancy, the reaction was positive 12 times. These 12 positive cases had either a fever or a tumor. In 37 cases of uterine carcinoma, the reaction with normal placenta was positive in 9 instances. In 28 cases of carcinoma of various organs, the reaction was positive with carcinoma tissue 23 times. In 13 of these cases that had been treated with X-rays and Ra emanations, the reaction was negative in 2 and weakly positive in the remaining.

JULIAN H. LEWIS.

Preliminary report on the study of protective enzymes of blood by the Abderhalden method after transplantation of organs. C. GOODMAN. New York. *Annals Surg.* 61, No. 2(1915); *J. Am. Med. Assoc.* 64, 1030.—Working with the thyroid it was found possible in 8 out of 14 specimens to demonstrate the presence in the blood of a protective enzyme capable of digesting suprarenal tissue. L. W. RIGGS.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

The effect of sodium salicylate on various types of experimental arthritis. DAVID J. DAVIS. Chicago. *Arch. Intern. Med.* 15, 555-7(1915).—The administration of Na salicylate to rabbits inoculated with various types of streptococci had no effect on the course of the infection. I. GREENWALD.

Action on the blood and the hematopoietic organs of benzene and its side-chain homologs. GUIBERTO BIANCHI. Siena. *Arch. sci. med.* 39, 1-45(1915).—Toluene, xylene, and cymene, injected into rabbits in doses of 1-2 cc. per kg. (the max. tolerated) produced a moderate leucocytosis and a notable hyperplasia of the leucogenetic elements, especially the bone-marrow; there also occurred a reduction of about 20% in the erythrocytes and a marked and persistent increase in the blood-platelets. Benzene, on the other hand, while affecting the erythrocytes similarly, causes an almost complete disappearance of the blood-platelets. This would seem to argue against the view that the platelets are genetically related to the erythrocytes. M. HENSELMEIER.

Quantitative researches on acetylation processes in the animal organism. II. Influence of acetic, pyroracemic and acetoacetic acids upon the formation of *p*-acetylaminobenzoic acids. MARIE HENSEL. Königsberg i/Br. *Z. physiol. Chem.* 93, 401-31(1915); cf. *C. A.* 9, 328.—The amt. of *p*-acetylaminobenzoic acid excreted by rabbits is increased 61.11% by the injection of AcONa, 32% by pyroracemic acid and 18% by Et acetoacetate, while AcH did not cause any increase. This indicates that pyroracemic and acetoacetic acids are decompd. with AcOH₂ as an intermediate step. The same results were obtained (differing in degree) with *p*-aminobenzaldehyde. Some of the expts. with this compd. indicate that the body stores the substances yielding AcOH, since the amt. of Ac deriv. is larger in the after-period than during the main part of the expt. G. M. MEYER.

Action of several indifferent narcotics upon the permeability of red blood corpuscles. ARTHUR JOEL. Univ. Kiel. *Arch. ges. Physiol.* 161, 5-44(1915).—Indifferent narcotics, when used in sufficiently small concn., produce a lowering of the increased permeability of red blood cells, artificially produced by other substances, thus retarding hemolysis. In higher concns. the indifferent narcotics are themselves hemolyzing. The importance of the surface tension and inner friction of narcotics for narcosis is discussed. The action of small amts. of narcotics upon permeability is reversible. C. J. WEST.

Morphine as an analgesic (BERTRAND) 17. Poisonous woods (MATTHES) 17.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Mate tea. A comparative study of stimulants. R. BRIEGER. *Pharm. Zentral-halle* 55, 975-8(1914).—Mate tea is prepd. from the leaves of *Ilex paraguariensis* and several other species of *Ilex*, indigenous to S. America. It yields a pleasant beverage that is considerably less astringent than ordinary tea. One sample yielded 2.5% caffeine, while a coffee gave 2.66%, a green tea 4.3%, and a black tea 4.6%. C. O. E.

A maximum stem content standard for tea. A. A. BESSON. Basel. *Chem. Ztg.* 39, 82(1915).—In the revision of the Schweiz. Lebensmittelbuch, it is proposed to limit the admissible content of stems in tea to a max. of 22%. B.'s investigations indicate that Chinese teas all have less than 22% stem content, Ceylon teas contain over 70%, India teas 60%, and those from Java 50%, of stems. Since the amt. of stems in any variety of tea depends upon the particular method of gathering and has no effect upon the quality of the tea, it is not advisable to have a max. stem standard for tea.

H. S. BAILEY.

The destruction of bacteria in milk by ultraviolet rays. S. H. AYERS AND W. T. JOHNSON. Washington. *Centr. Bakt. Parasitenk. Abt. II* 40, 109-13(1914).—It is shown that ultraviolet rays may markedly reduce the bacterial content of milk, but they have no effect on vegetative cells. This method of sterilizing milk could not replace pasteurization because there would be no assurance of the destruction of pathogenic bacteria. Ultraviolet rays impart to milk a disagreeable odor and taste which would render it unsalable.

JULIAN H. LEWIS.

The routine detection and estimation of boric acid in butter. HERBERT HAWLEY. *Analyst* 40, 150-2(1915).—*Turmeric reagent*: A mixt. of 5 g. powdered turmeric root and 5 g. tartaric acid is digested with 3 successive portions of 150 cc. warm alc. (industrial methylated spirits is satisfactory). Each digestion should continue for not less than 1 hr. and each successive portion should be filtered, and the vol. finally made up to 500 cc. with alc. The reagent should be kept in the dark. The *method*, which is rapid and approximate, is as follows: Place 20 g. of butter in a 40-50 cc. beaker, melt on a Cu tray over a water bath or steam oven, and keep warm until the curd and aq. layer have sepd., leaving the fat clear. Pour off the fat as far as possible onto a filter paper placed in a small beaker (taking care that none of the aq. layer is poured onto the filter), and det. the const. of the filtered fat in the usual manner. To the aq. residue in the beaker add 18 cc. dil. HCl (20 cc. conc. HCl per l.), stir, and keep warm for a few min. Allowing 2 cc. for the water in the butter, the 20 cc. of acid soln. contains the H_3BO_3 present in the butter, together with curd and a little fat. Remove 10 cc. of the fat-free liquid by means of a pipet dipped to the bottom of the liquid, and reject the liquid remaining in the beaker. Return the 10 cc. portion to the beaker. This portion is opalescent and almost free from fat, but contains a little curd. Allow the beaker to cool, and add 5 cc. of the turmeric reagent. The samples containing H_3BO_3 slowly develop a reddish brown color, the intensity varying with the amt. Approx. estimates may be made by comparison with standards containing 0.5 cc. milk plus varying amts. of a standard H_3BO_3 soln. (1 g. H_3BO_3 in 100 cc. dil. HCl (20 cc. conc. HCl per l.)), the mixt. being dild. to 10 cc. with the dil. HCl. Milk may be preserved with HCHO for the purpose. Add 5 cc. of the turmeric reagent to each standard and make comparisons not less than 1.5 or more than 3 hrs. after the addition. An unmistakable color is developed in the presence of 0.05% H_3BO_3 , and up to 0.5% can be estd. to the nearest 0.1%. The method is not recommended for samples containing more than 0.5% H_3BO_3 . A simple device for rapidly measuring approx. 20 g. samples of butter consists of a 6 in. glass tube having a $7/8$ in. bore. A plunger is made by boring a hole nearly through a solid rubber stopper which will just slide into the tube. A piece of narrow glass tubing with a bulb at the end is inserted in the hole and string tied tightly around the narrow end of the stopper. The plunger is raised and the tube pressed into the butter. The plunger is then pressed down to the mark which is adjusted so that the tube then contains 20 g., and the butter pressed out into the beaker.

P. B. DUNBAR.

The bacterial flora of Liptau cheese and its influence on the ripening and sharp flavor. O. GRATZ AND K. VAS. *Centr. Bakt. Parasitenk. Abt. II* 41, 481-545(1914);

Chem. Zentr. 1915, I, 492-3.—The lactic acid bacteria represented mainly by *B. casei* are most abundant in Liptau cheese. The accidental flora is the first to vanish. Only the *B. putrificus* group is able to do any harm by bad tastes and odors. Ripening is due specifically to the enzymes protease and lipase, and the mold *Oidium lactis*. The sharp flavor of Liptau cheese is due to the enzymes from fat-splitting bacteria or molds. If not due to these, it may be caused by a butyric acid fermentation.

FRED W. TANNER.

The application of hardened fats in the food industry. H. THOMS AND FRANZ MULLER. Berlin. *Arch. Hyg.* 84, 56-77(1915).—An extensive study was made of the chem. and physical properties and physiological action of peanut oil, pine oil, and cottonseed oil which have been altered by a patented process so that they have a higher m. p. Feeding expts. on man and animals indicate that they are harmless and are to be considered as useful articles of diet.

JULIAN H. LEWIS.

Pure bread and flour. ANON. *Chem. News* 111, 176-7(1915).—A memorial to the President of the Local Govt. Board (Eng.) and suggestions made by the Council of the Bread and Food Reform League thereon. The Board is urged to prevent the abstraction from whole meal, wheat meal, etc., of the "germ" and the strong gluten found in "Patent" flours. Also if bleaching and the use of so-called "improvers" cannot be prohibited, it is urged that places selling bread made from bleached flours be required to display a notice to the effect that such flours are used. Numerous publications relative to the value of whole wheat flours and the minute quantities of certain substances, "vitamines," are quoted. In England, only 70 tons of white flour are made from 100 tons of wheat, while 88 tons of better and more nutritious flour can be made.

H. S. BAILEY.

Note on the determination of sulfates in flour. G. D. ELSDON. *Analyst* 40, 142-3(1915).—The following method is recommended in the case of self-raising flours containing CaHPO_4 : Add 10 g. flour to 25 cc. conc. HCl in a 250 cc. beaker. Warm gently on a water bath for a few min. until all the flour has been attacked and the liquid is a deep purple color. Finally heat on a hot water bath for about 1 hr. without allowing the beaker to come in contact with the steam. Add 100 cc. water, and after standing a few min. filter the liquid and wash the filter once with cold water. Heat the filtrate to boiling, add BaCl_2 and weigh the pptd. BaSO_4 . When detg. sulfates in a phosphatic self-raising or an "improved" flour, 0.025% CaSO_4 should be allowed as that due to the sulfate normally present in flour.

P. B. DUNBAR.

The ash content of black bread. K. SCHERINGA. *Pharm. Weekblad* 51, 1419 (1914); *Chem. Zentr.* 1915, I, 268.—According to the codex, black bread with more than 1% ash is not suitable for use. This is an error, since the flour used in making this bread may contain more ash.

E. H.

The influence of temperature on the microflora of hay; lactic and butyric hays. C. GORINI. *Rend. r. accad. Lincei* [5] 33, I, No. 12(1914); *Bull. Agr. Intelligence* 5, 1626-7.—G. applied the methods of silo research (C. A. 9, 1442) to hay. The results confirm those obtained in the case of the silos. Normal hay may be classified as lactic or butyric according to the predominant microflora. During the first 3-5 days of fermentation with a temp. of 50-55° the hay was prevailingly lactic. As the temp. gradually rose to 60-65° the mass tended to become more butyric. Most hay is of the butyric type and consequently less favorable to the intestinal functions of live stock and to the sanitary condition of milk and its products. To obtain lactic hay care should be taken in stacking to expel as much air as possible and to maintain a temp. of about 50°.

M. X. SULLIVAN.

The preparation of ensilage. F. SAMARANI. *Boll. ministero agric.* 13, Nos. 8-12, pp. 87-103; through *Bull. Agr. Intelligence* 5, 1625(1914).—During the first

few days after the grass has been put into the silo, an acetic and a lactic fermentation of the sugars and cell-sap takes place. The sugars, in an almost complete absence of O, are first converted into EtOH and CO₂; then by chem. or physiological, certainly not by bacterial, action the EtOH is changed to AcOH. The 2nd process, due to bacilli, is an ordinary lactic acid fermentation. About 70% of the total free acid is AcOH, 20% lactic and 10% butyric. If sufficient acidity is not soon attained, a putrefactive fermentation sets in. This is best prevented by adding dil. lactose to the ensilage. To make good ensilage it is necessary to avoid overheating, to limit the AcOH production and leave the sugars, also, for the lactic fermentation. This can be done by applying mechanical pressure as soon as the silo is full, thus forcing out the air. Where pressure is used the fodder contains 70% lactic and 20% acetic acid, while with the ordinary silo these proportions are reversed.

EDWARD BARTOW.

Contributions of the chemist to the potable water industry. W. P. MASON. *J. Ind. Eng. Chem.* 7, 289-90(1915). ISADOR MILLER.

Contribution to water analysis. Rapid determination of magnesium by titration in the presence of calcium. VICTOR FROBOESE. Berlin. *Z. anorg. Chem.* 89, 370-6 (1914).—In the detn. of hardness in water analysis, Blacher's method (*C. A.* 7, 1938) is used for total hardness. Ca is pptd. as CaC_2O_4 , and Mg is titrated with K palmitate soln., without removing the ppt. Ca is detd. by difference. 200 cc. (samples up to 1 l. may be used) of the water are heated to boiling; 1 drop methyl orange is added; then an excess conc. $\text{H}_2\text{C}_2\text{O}_4$ soln.; then enough 50% KOH just to give the yellow color (an excess is to be avoided). The soln. on cooling should regain a slightly reddish tint. To the cooled soln. add 5 drops phenolph. and just enough 0.1 N KOH to give a weak rose tint, then titrate with 0.1 N K palmitate. The results given are good. In the Winkler method (*C. A.* 8, 2912) instead of taking the end point as the rather indefinite "permanent lather," F. titrates until the sound of the bubbles breaking can no longer be detected when holding the titrating flask close to the ear. G. W. M.

Colorimetric determination of nitrous acid. G. ROMIJN. *Chem. Weekblad* 11, 115-6(1914).—For the detn. of HNO_2 in drinking water, the ordinary colorimetric method with α -naphthylamine and sulfanilic acid is modified by adding the reagent in the form of a dry powder containing α -naphthylamine 1, sulfanilic acid 10 and tartaric acid 89 parts. The chief disadvantage of the method is caused by the fact that when the sample contains more than 0.15 mg. NO_2 per l. the pigment of the indicator ppts. This may be recognized by the rapid production of a too intense color, and remedied by diln. and addition of more reagent. The formation of a yellow color indicates too little reagent. The best procedure in case large amts. HNO_2 are present is to add NH_4OH as soon as the color becomes too strong, thereby forming sol. NH_4NO_2 (the addition should be continued until the red color changes to yellow). The soln. is dild., acidified with AcOH , and more of the above reagent is added. G. W. M.

The distillation of sea water to render it potable. ERNST GOLZ. *Chem. App.* 2, 5-7, 17-19(1915).—Five cuts show details of an app. which it is claimed will yield 100-240 lbs. H_2O per lb. coal, and 1 cut shows an app. at Baku for 1,800,000 l. daily. J. H. MOORE.

The normal chlorine content of surface waters of Western Florida and a comparison of volumetric methods of chlorine analysis. C. A. BRAUTLECHT AND B. N. LANGLEY. *J. Ind. Eng. Chem.* 7, 357-8(1915).—Comparing the Volhard and Mohr methods, using 0.1 N solns., the former gives more satisfactory, concordant and accurate results but takes longer. Both 0.01 N NH_4CNS and 0.01 N AgNO_3 are too dil. to give sharp endpoints but careful manipulation of a 0.1 N soln. gives as accurate results as the use of more dil. solns. ISADOR MILLER.

Feed water and its treatment. WILLIAM BARROWMAN. *Iron Coal Trades Rev.* 89, 180-2(1914).—A review of methods. H. L. OLIN.

Description of Navy standard boiler water-testing outfit. ANON. *U. S. Navy Dept. Circ.* 12 pp. R. S. MCBRIDE.

Air-bound filters. JAMES M. CAIRD. *J. Am. W. W. Assoc.* 2, 103-6(1915).—Air-bound filters are caused by the release of air from the water during cold weather, particularly when the temp. of the water is below 50° F. The released air collects in the voids of the gravel, and in rapid sand filters perforates the sand beds. In slow

sand mits the wt. of the sand holds the air in the gravel and prevents the water passing through the bed. C. advises back washing the beds to overcome the trouble.

S. T. POWELL.

Collapseable hypo plant packed in a trunk. H. A. WHITTAKER. *U. S. Public Health Rept.*, Feb. 26, 1915; *Eng. Record* 71, 373(1915).

F. BACHMANN.

Philadelphia water filter operations in 1914. C. E. DAVIS. *Eng. News* 73, 576-7(1915).—Tables show costs, method of operation and physical, bacterial and chem. analyses. Av. turbidity is 20.2 p. p. m. for raw water, 9.5 p. p. m. for applied water. Bacteria in raw water average 16,800 per cc. and in filtered water 51 per cc. Gelatin counts (20°) are from 4 to 8 times as high as agar counts at 37°. Cost per mil. gals. ranges from \$2.23 to \$5.10 in different plants.

LANGDON PEARSE.

Toronto test of drifting sand filters. G. D. NASMITH AND FRED ADAMS. *Can. Eng.* 28, 433-8(1915); *Eng. News* 73, 680-1(1915); *Eng. Rec.* 71, 464-5(1915); *Eng. Contr.* 43, 351-2(1915).—This describes a test of a 500,000 gal. filter in which the sand is constantly being removed, washed and replaced by mixing with raw water. A coagulant, $Al_2(SO_4)_3$, is used, but no coagulating basin is provided. In a 36-day test 99.0% of bacteria were removed (agar 37°). In washing, 2% raw and 1% filtered water are used. Av. rate of filtration was 149 mil. Imp. gal. per acre per day. The initial loss of head was 7 ft. and the final loss 14 ft.

LANGDON PEARSE.

Water supply treatment of Council Grove, Kansas. L. L. TRIBUS. *J. Am. W. W. Assoc.* 2, 83-102(1915).—A description of a remodeled mechanical filter plant operated in connection with sedimentation basins. During test periods the dose of alum used was as high as 20 grains per gal. It was later reduced to from 4 to 6 grains, and in cold weather 0.5 grain has been successful. A detailed report of the results obtained during the test of the plant is given. The use of $Ca(OCl)_2$ at a rate of 8 to 10 lbs. per mil. gals. of water is advised.

S. T. POWELL.

English experiments on sewage aeration reviewed as preliminary to Baltimore tests. LESLIE C. FRANK. *Eng. Record* 71, 288-9(1915).—F. enumerates features of the activated sludge process at Manchester and Salford as described by Arden and Lockett (C. A. 8, 2207, 2766). A continuous flow tank will supersede draw and fill methods.

FRANK BACHMANN.

The Milwaukee sewage tests. ANON. *Eng. News* 73, 650-1(1915).—The sewage testing station includes coarse screening ($1\frac{1}{4}$ in. openings in bar, or 16-mesh), grit chamber, Imhoff tank, chemical pptn., colloid or slate tank with forced aeration sprinkling filters, and liquid Cl. The slate tank is but little more effective than an Imhoff tank.

LANGDON PEARSE.

Garbage and rubbish incinerator recommended for Albany, N. Y. RUDOLPH HERRING AND JOHN H. GREGORY. *Eng. News* 73, 565(1915).—A high temp. garbage

and rubbish incinerator is recommended, with the use of steam to pump sewage, and the use of clinker for concrete pavement foundation. A capital outlay of \$199,650 for disposal and \$35,420 for collection equipment is required. LANGDON PEARSE.

The sludge disposal plant at Frankfort a/M. H. SCHAEFER. *Gesundh. Ing.* 38, 97-108, 109-118(1915).—The av. comp. of the sewage sludge is: sp. gr. 1.02, H_2O 90, org. volatile matter 65, fixed matter 35, org. N 2-3 and fats 10-15%. The last 4 constituents are calcd. on a dry basis. Expts. were made with simple drainage on sand and utilization of sludge as fertilizer, mixing the sludge with garbage, drying it in a centrifuge, filter pressing, and prepg. briquettes. None of these processes has been found to be economical. The extn. of fat likewise has not proved economical. Expts. on mfg. illuminating gas failed on account of inability to obtain sufficient quantities of the dry sludge. The yield of gas, however, came up to expectations. A number of other procedures which had for their object improvement in the sludge drainage proved too costly. Among these are the electro-osmotic process and the lime process. After centrifuging, the sludge had a H_2O content of 60-70%. Expts. carried on over several years proved the practicability of sludge drying by the use of the centrifuge, and a large plant was installed. A complete technical description of the plant is given. The centrifuged sludge is mixed with garbage and incinerated. Previous to incineration the sludge is still further dried in drums by utilizing the excess heat of the garbage incineration plant. Throughout the entire process the sludge is not touched by hand. All conduits, conveyers, and app. are enclosed. The heat resulting from the incineration of the sludge and garbage is converted into steam and elec. current. Preliminary figures seem to indicate that the cost is almost covered by the sale of elec. current. The plant is the first one on the continent which has solved the sludge problem in a thoroughly satisfactory manner.

ARTHUR LEDERER.

Sewage treatment at Hagen (Westphalia). ENDRIS. *Der Städtische Tiefbau* 5, 57-66, 69-76(1914); *Wasser u. Abwasser* 9, 161-3(1915).—The effluent discharges into the Ruhr. For the present the plant takes care of a population of 60,000. The sewage is roughly screened, after which it passes into a grit chamber at a velocity of 0.1 m. per sec. and into Emscher settling tanks, of which there are 16. The flow in the tank is 120 l. per sec. for 2 hours. The sludge is drained and dried on sand. The installation of trickling filters is contemplated when necessity arises. A. L.

Portable disinfection apparatus in warfare. F. A. EBERT. *Gesundh. Ing.* 38, 87-9(1915); illus.—Description of an app. which can be used for steam disinfection at a temp. of 100-110° as well as for formaldehyde-steam disinfection at 60-65°. The latter is employed for more sensitive material, such as furs and leather goods. The technical features and mode of operation are discussed.

15. SOILS AND FERTILIZERS.

M. X. SULLIVAN.

The atmosphere of the soil, its composition and the cause of variation. E. J. RUSSELL AND A. APPELYARD. *J. Agr. Sci.* 7, 1-44 (1915).—The free air in the pores of the soil to a depth of 6 inches is very similar in comp. to the atm. air but differs in 2 respects: (a) It contains more CO_2 and correspondingly less O_2 , the av. in 100 vol. being 0.25 vol. CO_2 and 20.6 of O_2 against 0.03 vol. CO_2 and 20.96 O_2 in atm. air. (b) It shows greater fluctuations in comp. Usually the sum of the CO_2 and O_2 is only slightly less than in atm. air but at periods when nitrates rapidly increase there is a falling off of O_2 , and a still greater one in water-logged soils. Besides this free air there is another atmosphere dissolved in the water and colloids of the soil. This consists mainly of CO_2 and N and has practically no O_2 . The fluctuations in comp. of the free soil air are mainly due to fluctuations in the rate of biochem. change in the soil, the curve being similar to those showing the amt. of nitrate and the bacterial counts as far as they were taken. The rate of biochem. activity attains a max. value in late spring and again in autumn, and min. values in summer and winter. In autumn the bacteria increase first, then the CO_2 rises, and finally the nitrate increases. From Nov. to May the curves closely follow those for the soil temp. which thus appears to be the dominant factor; from May to Nov. they follow the rainfall and to a less extent the soil moisture curves. The difference between rainfall and soil moisture indicates that rainfall does something more than add H_2O to the soil. It is shown that the dissolved O_2 brought in is probably a factor of considerable importance in renewing the dissolved soil atm. and facilitating biochem. change. Grass land usually contains more CO_2 and less O_2 than arable land. This difference cannot be attributed to the crop owing to the larger differences in soil comp. and conditions. No evidence could be obtained that the growing crop markedly increases the amt. of CO_2 in the soil air and if it gives rise to any great evolution of CO_2 in the soil it apparently exercises a corresponding depressing effect on the activities of soil bacteria. Such weather conditions as barometric pressure, wind velocity, variations in temp. from the mean, small rainfall, etc., seem to have but little effect on the soil atmosphere. M. X. SULLIVAN.

The fertility relations in different strata of a soil profile. A. F. v. NOSTITZ. *Landw. Jahrb.* 47, 113-52 (1914); *Chem. Zentr.* 1915, I, 214-5.—Pot expts. were carried

out on 3 different soil types to det. the vegetative relations existing between the soil and subsoil at various depths as well as the causes responsible for the poorer productivity of the subsoil. The results are summed up as follows: the productivity of the soil becomes less with increasing depth. The differences in the plant yields were diminished by the use of fertilizers but they were not eliminated entirely. The mineral content of the separate crop products did not decrease at the same rate as the crop yield; there may be even a higher % in the lower strata. As causes for the lower soil fertility of the soils in the deeper strata, the following are given: (1) lower bacterial content, (2) lower humus content, (3) lower N content and (4) smaller amt. of available P_2O_5 .
C. F. MILLER.

The origin of "nitre spots" in certain western soils. R. STEWART. *J. Am. Soc. Agron.* 6, 241-8 (1914).—The nitrates of the nitre spots of Colorado, Utah, and Wyoming are derived by concn. from the original rocks contributing to the soil formation. The color of the spots is the direct result of the solvent and decomposing action of the $NaNO_3$ or KNO_3 upon the organic matter of the soil. The nitre spots are not characteristic of irrigated, cultivated soils, but are also produced in uncultivated areas whenever the ground water conditions are favorable for their formation. M. X. S.

Relation of chemical composition to soil fertility. G. S. FRAPS. *J. Am. Soc. Agron.* 7, 33-6 (1915).—Three methods given for detg. soil fertility are field expts., pot tests and chem. analyses. An average of a large number of pot expts. at the Texas Exp. Sta. shows that the active P_2O_5 and K and the total N are directly related to the soil deficiencies brought out by the plant's growth.
J. J. S.

Petrography of various soils derived from volcanic ejecta. W. H. FRY. *J. Am. Soc. Agron.* 6, 164-71 (1914).—Mechanical and mineralogical analyses of a number of soils from the U. S. and Hawaiian Islands, known to be of volcanic origin, are reported. It is stated that the presence of glassy material in a soil is generally an indication that it is of volcanic origin. The soils examd. fall into 3 groups: (1) very silicious soils containing much quartz and material of low refractive index, (2) soils containing little or no quartz and large amts. of material of higher refractive index and also much olivine, and (3) soils characterized especially by the presence of well developed lime soda feldspars.
C. F. MILLER.

Study of methods used in alkali determinations. A. E. VINSON AND C. N. CATLIN. *Aris. Sta. Rpt.* 1913, 274-7.—Comparative tests of the Calif., Montana, Bur. of Soils, Texas, N. Mexico, Utah and Arizona methods on a very black alk. soil, a moderately black alk. soil, and a gypsum soil, showed that the Arizona method gave high results for all detns. except chlorides. A large proportion of water to soil and long digestion are required to ext. the max. of solids.
WM. P. GARRETY.

The partial sterilization of soils. E. J. RUSSELL. *Nature* 94, 308-11 (1914).—A summary of the results of investigations on the effect of partial sterilization of soil by means of heat, lime, and volatile antiseptics on the growth of plants and on the relation of protozoa thereto.
B. E. B.

Antagonism between anions as affecting soil bacteria. CHARLES B. LIPMAN AND PAUL S. BURGESS. *Centr. Bakt. Parasitenk. Abt. II* 42, 502-9 (1914).—Very slight, perhaps questionable antagonism between anions occurs for the N-fixing flora of sandy soil from Anaheim, Cal., when Na_2CO_3 and $NaCl$ are mixed, whether one or the other is used as a constant toxic factor. The same is true when $NaCl$ and Na_2SO_4 are combined provided the first named salt is the const. toxic factor. It is not true when Na_2SO_4 is used as the const. toxic factor. No antagonism is obtained between Na_2CO_3 and Na_2SO_4 , no matter which of them is used as the const. toxic factor. The concs. at which N fixation ceases are lower when the salts are mixed than when they are used singly.

The N-fixing flora differ totally in respect to antagonism between anions from the ammonifying and nitrifying flora of the same soil. The resistance of these N-fixing flora, however, to the effects of salt is far greater than that of the other flora named.

JULIAN H. LEWIS.

Notes on some methods for the examination of soil protozoa. C. H. MARTIN AND K. R. LEWIN. *J. Agr. Sci.* 7, 106-18(1915).—It is pointed out that the protozoan population of any soil should be studied for the detection of active fauna, active fauna in fresh fixed films and for cultural fauna. Soils of different types including some from the Rothamstead exptl. field were examd. and protozoa were found present in all unproductive samples. Protozoa may be added to soils in farmyard manure and if conditions of culture are such as to necessitate high water and manure content they develop and produce harmful effects. The dominant active fauna of the soils examd. consists mostly of amebae, thecamebae and small flagellates. Large flagellates and ciliates are relatively rare. The character of the soil, water content and cultural method det. the development of the species.

J. J. SKINNER.

Studies on soil protozoa. A. CUNNINGHAM. *J. Agr. Sci.* 7, 49-74(1915); see C. A. 9, 1361.

M. X. S.

Proof of the origin of smoke acids in rain-water flowing down tree trunks by means of an automatic separator and the influence of these acids on the soil. R. GERLACH. *Samml. Abhandl. Abgase u. Rauchschäden* No. 9, 47 pp.(1914); *Expt. Sta. Record* 32, 422.—The app. permits the sep. collection of rain-waters from diff. smoke sections and the detn. of their acidity. Cropping expts. were conducted. Germination, particularly that of fruit trees, vetch and beans was noticeably retarded by the so-called smoke-sickness of the soil. By substituting pure rain-water for the water contg. smoke acids the more hardy grasses recovered and continued to develop. Analyses of certain soils showed them to be acid, owing to lime exhaustion by the smoke acids in the rain-water. Smooth bark trees were more injured than rough bark trees, and deciduous trees were more injured than evergreen trees.

B. E. BROWN.

Moisture relations of Texas soils. G. S. FRAPS. *J. Am. Soc. Agron.* 7, 31-3 (1915).—It is shown that the application of manure and cultivation of clays and clay loams cause only a little saving of moisture under Texas conditions, while the same treatments of sands and sandy loams cause a decided gain in the conservation of moisture.

J. J. S.

Some unusual soils that occur in Oregon. M. M. MCCOOL. *J. Am. Soc. Agron.* 6, 159-64(1914).—Soils in central Oregon where a great deal of pumice has been deposited are described. Mineralogical exam. showed the presence of material derived from basic as well as acidic rock. The amt. of K, Ca and Mg is abnormally high, the total salts being low. The sub-soil contains more sol. material than the surface. These soils have but little agricultural value unless fertilizer and organic matter are added.

J. J. SKINNER.

Soils of Massachusetts and Connecticut with special reference to apples and peaches. H. J. WILDER. U. S. Dept. Agr., *Bull.* 140(1915).—The principle soil types suitable for various kinds of apples and peaches in these states are described and methods of development discussed.

J. J. SKINNER.

Mutual influences of certain crops in relation to nitrogen. K. F. KELLERMAN AND R. C. WRIGHT. *J. Am. Soc. Agron.* 6, 204-10(1914).—Legumes and non-legumes when grown together both showed an increase in % of N. A reduction in the % of N of the soil occurred by the growth of peas, vetch, barley, rye, and beans in one of the soils experimented with, while the reduction in N of another soil used was not as marked. In the case of non-legumes, especially barley, an actual loss of soil N occurred

above that utilized by the plants. The effect of a given crop upon 2 different soils may be very different both in regard to its effect upon the total soil N and upon the nitrifying power of the 2 soils.
J. J. SKINNER.

Percentage of protein in non-legumes and legumes when grown alone and in association in field mixture. J. M. WESTGATE AND R. A. OAKLEY. *J. Am. Soc. Agron.* 6, 210-15 (1914).—Analyses of 19 samples of non-legumes from fields of typical fertility in several different states and under conditions typical of the surrounding sections, when grown with legumes, showed variations in protein content from 2.02% above to 2.61% below that when grown alone. The protein in the associated legume may also be decreased. It is concluded that the phenomenon of increased protein content in the non-legume because of association with the legume is not so universally true as to make it safe to advocate the method unreservedly as a means of increasing the production of protein.
M. X. S.

The composition and quality of wheat grown in mixtures with oats. C. H. BAILEY. *J. Am. Soc. Agron.* 6, 215-17 (1914).—Expts. carried on at the Minnesota Station showed that wheat grown in mixt. with oats did not vary in comp. and quality from that grown alone.
M. X. S.

Observations on the efficiency of the most important nitrogenous fertilizers. S. OSWALD AND W. WEBER. *Landw. Jahrb.* 47, 79-106 (1914); through *Chem. Zentr.* 1915, I, 215.—Expts. carried out with $(\text{NH}_4)_2\text{SO}_4$, Chile saltpeter, blood meal and CaCN_2 , led to the conclusion that the relative efficiency of the different N fertilizers cannot be expressed by rigid values. A certain advantage of the Chile saltpeter over the other substances is accounted for by the following reasons: (1) Since, in contrast to that of the other materials, its N is in the form required by plants, it is less dependent on certain prescribed conditions; (2) it is nearly entirely available the first year, whereas in the other cases considerable time is required for the conversion of N to NO_3 . $(\text{NH}_4)_2\text{SO}_4$ proved to be on a par with the saltpeter, as did CaCN_2 when used on rape and potatoes. Mixts. of CaCN_2 and saltpeter also gave good results with beets and sugar beets.
C. F. MILLER.

Combined nitrogen for fertilizer. WALTHER HEMPEL. *Z. angew. Chem.* 28, I, 145-7 (1915).—A discussion of urine and excrement as sources of combined N.
W. H. FRY.

Perchlorate in Chile saltpeter. J. G. MASCHHAUPT. *Direktie van dem Landbouw.* 1914, 1-17; *Chem. Zentr.* 1914, II, 1466.—The perchlorate disease of corn is caused by KClO_4 in Chile saltpeter. The av. sample contains about 1.5% KClO_4 . The amt. of injury depends on the kind of grain and the amt. of KClO_4 in the saltpeter. Fertilizer expts. with Chile saltpeter with and without KClO_4 gave irregular results.
E. H. WALTERS.

Fertilizer and oil manufactured from dog fish. E. E. YOUNG. *Daily Cons. and Trade Rpts. (U. S.)* 17, 1373 (1914); *Exp. Sta. Record*, 32, 424 (1915).—An account is given of the production by Nova Scotia and New Brunswick factories of fertilizer and oil from dog fish.
J. J. S.

Dog fish and how it is made into fertilizer. L. B. MARTELL. *Ann. Fertilizer* 42, No. 8, 34-8 (1915).—The process of coking, pressing and drying dog fish for fertilizers is described. It yields a fish scrap high in N.
J. J. S.

Flue dust (from iron works) as fertilizer. *J. Board Agr.* 21, 1043-6 (1915); *J. Soc. Chem. Ind.* 34, 369.—A sample of flue dust from iron works contained nearly 6% K_2O (about $\frac{1}{2}$ was sol. in H_2O) together with about 7% CaO as gypsum. No substance directly injurious to plants was present and the water-sol. Mg was only

0.29%. It is doubtful whether the K could be extd. profitably but the material could be used locally as fertilizer.

M. X. S.

Composition and use of some of the new fertilizer materials. Fertilizing value of some local by-products. H. D. HASKINS. Mass. Agr. Expt. Sta., *Bull.* 155, 173-81 (1914).—The comp. and use of such materials as sheep manure, wool waste, wool waste free of grease, whale guano, rock weed and other recently introduced fertilizers are considered. General information concerning home-mixing, etc., is given.

B. E. BROWN.

Fertilizing materials. F. T. SHUTT. *Canada Exp. Farms Rpt.* 1913, 245-59; *Exp. Sta. Rec.* 32, 424 (1915).—Analyses of marl, limestones, lime-kiln ashes, gypsum, wood ashes, K residue from $O-C_2H_2$ plants, marsh, river and oyster muds, mucks, fish scraps and $Ca(NO_3)_2$ are given and discussed

J. J. S.

The chemical composition of several weeds as well as their value as feed and fertilizer. M. KLING. *Landw. Vers. Stat.* 85, 433-69 (1914); *Chem. Zentr.* 1915, 1, 215.—Analyses of the weeds occurring most abundantly in Rhenish Bavaria show that they remove large amts. of nourishment from the soil. The following proved suitable as green forage plants: cornbind, common goose foot, horse thistle, chickweed, and sow thistle. All of the weeds investigated have an appreciable value as fertilizers due to their high plant-food content.

C. F. MILLER.

Salton sea water. A. E. VINSON AND C. N. CATLIN. *Aris. Sta. Rpt.* 1913, 272-4.—In one year, 1912-3, total solids increased from 846.55 to 1,002.56 parts per 100,000, and the water is now about 1% brine. Ca is decreasing and K is disappearing rapidly. In 1911 the ratio of K to Na to total solids was 1:59.8:188; in 1912 it was 1:71.1:222; and in 1913 it was 1:94:288.

WM. P. GARRETY.

The relation of sulfur to soil fertility. O. M. SHEDD. Ky. Agr. Expt. Sta., *Bull.* No. 188, 35 pp. (1914).—Tables are presented showing total S content of different plants and, in addition, the % of S and P in type samples of Ky. tobacco. The av. P content of this tobacco was 0.458% and S 0.302%. Sulfur or sulfates benefited the following crop plants: Soy beans, turnips, tobacco (Graves Co. soil). Clover was not benefited by the addition of S compds., K_2SO_4 alone being of value, due to the K. Of the sulfates of Fe, Ni, Cu, Co, Cr, Mn, Li, etc., using cabbage as test crop, only two (which two not stated by S.) proved beneficial, a few had no effect, while several were harmful to the plant. The results with mustard were better in that several of the sulfates gave higher yields than the checks. The results with radishes were irregular. Fertile soil oxidized S to sulfate more rapidly than did poor soil. The org. S of horse manure was found to be slowly changed to sulfate.

B. E. BROWN.

Observations and investigations of injury to vegetation, as well as fertilizer experiments in Ratibor-planina. R. OTTO. *Jahresber. Kgl. Lehran. Gart. Proskau* 1913, 116-118.—A plot of ground subjected to the tar oil fumes from the Plania factory, was divided into 6 parts, 5 of which were treated with one of more of the following fertilizer materials: $CaCO_3$, $(NH_4)_2SO_4$, superphosphate, and potash salt, the 6th being used as a control. None of the materials used either separately or in combinations exerted a protecting influence on the plants which showed the same typical injuries as the check plot and other vegetation in the neighborhood.

C. F. MILLER.

Studies on the lime requirement of soils. H. B. HUTCHINSON AND K. MACLENNAN. *J. Agr. Sci.* 7, 75-105 (1915); see C. A. 8, 3340.

Is the doctrine of the lime factor an hypothesis or a proved theory? E. HASELHOFF. *Landw. Jahrb.* 47, 107-8 (1914).—Remarks upon Loew's article in (C. A. 8, 3701).

Is the doctrine of the lime factor an hypothesis or a proved theory? O. LOEW. *Landw. Jahrb.* 47, 109-11(1914).—An answer to Haselhoff (cf. preceding abstr.).

M. X. S.

A new theory regarding the feeding power of plants. E. TRUOG. *Science* 41, 616-18(1915).—The hypothesis is: "Plants containing a relatively high CaO content have a relatively high feeding power for the P in raw rock phosphate. For plants containing a relatively low CaO content the converse of the above is true." CaO content of less than 1% is relatively low; in this class fall corn, oats, rye, wheat and millet. CaO content in excess of 1% is relatively high; in this class belong peas, clover, alfalfa, etc. The above is explained by means of the laws of mass action and chem. equil. The P in raw rock phosphate is made available in accordance with the following reaction: $\text{Ca}_3(\text{PO}_4)_2 + 2\text{H}_2\text{CO}_3 \rightleftharpoons \text{Ca}_2\text{H}_2(\text{PO}_4)_2 + \text{CaH}_2(\text{CO}_3)_2$. Equil. is attained if none of the products to the right of the reaction are removed from soln. Plants which remove considerable lime will enable the reaction to proceed much farther than where little lime is removed. This difference in the lime-absorbing power of different plants causes a variation in the solubility of raw rock phosphate in carbonated water. "The feeding power of a plant for an insol. substance depends primarily upon 2 conditions, viz., (1) the solubility of that substance in carbonated water and, (2) whether or not the plant removes from soln. all the products of the solubility reaction in the proper proportions, so as to allow the solubility reaction to continue indefinitely."

B. E. B.

Field tests with a toxic soil constituent; salicylaldehyde. O. SCHREINER AND J. J. SKINNER. *J. Am. Soc. Agron.* 6, 108-12(1914); cf. *C. A.* 8, 3478.—In field expts. on a heavy silt clay loam low in organic matter, the application of 105 lbs. of salicylaldehyde in 3 equal applications decreased the growth of garden peas, cowpeas, and string beans in the order given, the string beans least. Aldehyde was found in the soil 6-7 mos. after the last application. In pot culture the soil was still harmful to wheat and to garden peas, cowpeas, and string beans. The relative toxicity to the last three crops was of the same order as in the field.

M. X. S.

Action of radioactive fertilizers on sugar beets. J. CROCHETTELE. *J. agr. prat.* 28, 344-6(1915).—In a field expt. with radioactive fertilizer the % of sugar in beets was slightly decreased, the quality of sugar improved, and the green matter of the plant increased. The compn. of the fertilizer is not given.

J. J. S.

Employment of sulfuric acid in fields of cereals. H. HITIER. *J. agr. prat.* 28, 347-8(1915).—The results of expts. with H_2SO_4 in eradicating weeds from cereals were presented to the National Agr. Soc.; they show that 5-10% H_2SO_4 is more effective than FeSO_4 or CuSO_4 . The undesirable herbs killed were mustard, wallflower, crow foot, bluet, wall poppy, vetches and grasses. No harmful effects were produced on the wheat. An increased growth was observed, due to utilization of sulfates or liberation of nutrients in the soil. The wheat remained free from disease and produced full grains.

J. J. SKINNER.

Green manuring. *Bol. agr. (Sao Paulo)* 15, 525-7(1914); *Exp. Sta. Record* 32, 423.—Analyses of 5 green manures are given. From the point of view of the amt. of N and organic matter they stand in the following order: *Canavalia gladiata*, *Arachis prostrata*, cowpeas, velvet beans and peanuts.

J. J. S.

Lime and the American vine. G. DE ANGELIS D'OSSAT. *Staz. sper. agrar. ital.* 47, 603-20(1914); through *Chem. Zentr.* 1915, I, 392.—Chlorosis of vine depends not so much on the abs. amt. of CaO in the soil as on the greater or less solubility of the CaO. App. for the detn. of this solubility is described. The crystal system to which the CaO compd. belongs influences the solubility, calcite dissolving considerably

more easily than aragonite. Clay and humus of the soil also influence the solubility.
W. H. FRY.

Arsenic and lead in agriculture. A. CUTOLO. *Boll. chim. farm.* 53, 692-6(1914); *J. Chem. Soc.* 108, I, 204.—Spraying with solns. or suspensions of As, such as lead arsenate, for the purpose of destroying parasitic organisms, nearly always results in the presence of As and Pb in the foodstuffs obtained. Extended use of such sprays may lead to poisoning and the necessity of prohibiting or regulating their employment is indicated.
M. X. S.

Potato spraying. DUKE OF BEDFORD AND S. U. PICKERING. *Woburn Expt. Fruit Farm Rpt.* 14, 1-32(1914); *Gard. Chron.* 56, 461(1914).—Woburn Bordeaux paste was found as efficient as ordinary Bordeaux mixt. containing 5 or 6 times as much Cu. The paste is made by pptg. a soln. of CuSO_4 with clear lime water enough to make the mixt. slightly alk. The ppt. is mixed with water. Soda Bordeaux was found to be much less efficient than either of the other mixts., even with very large amts. of Cu.
WM. P. GARRETY.

Linseed as a farm crop (EYRE) 27.

U. S., 1,137,065, Apr. 27. W. S. LANDIS. **Rendering phosphate rock available as a fertilizer** (citrate-sol.) by heating finely divided phosphate rock 100 with Na_2SO_4 20 and C 15 parts, to about 1000° to eliminate the sulfate radical, and then raising the temp. to cause incipient fusion or clinkering of the mixt. The product, if finely ground, shows 90% of the P_2O_5 present in citrate-sol. form. Cf. C. A. 8, 3093.

U. S., 1,137,531, Apr. 27. G. L. PRATT. **Making acid-phosphate fertilizer.** A viscous mass of mixed phosphatic dust and acid is allowed to partially cure in a curing den and the dry friable partially cured material is carried on a horizontal conveyor and dumped into another den at a lower level, for final curing. This mode of handling avoids any rubbing or pressing of the mass which might convert it into a sticky or gummy condition.

U. S., 1,137,844, May 4. R. M. CHAPIN. **A concentrated animal dip** is formed by dissolving 4 lbs. of NaOH and 10 lbs. As_2O_3 in 1 gal. H_2O , adding 10 lbs. Na_2CO_3 and sufficient cool H_2O to bring the vol. up to 5 gals., further dilg. the soln. as desired and then adding a mixt. formed from NaOH 8 oz., pine tar 1 gal. and H_2O 1 qt.

U. S., 1,138,348, May 4. E. BOHON. **Forming soluble foods (or fertilizers)** from fresh (or spoiled) meat or fish by dissolving in a boiling 5% soln. of caustic alkali, removing the oils and fats which rise to the surface, neutralizing with an excess of HCl or H_3PO_4 and then neutralizing the excess of acid with NaHCO_3 and concg. the soln. Old leather, hair, whales, dauphins, etc., may be similarly treated to make a fertilizer.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Detailed analysis of wine. W. I. BARAGIOLA. *Schweiz. Apoth. Ztg.* 53, 117-9 (1915); cf. C. A. 8, 1636, 3480.—Results obtained by Mensio and Garino-Canina (cf. C. A. 8, 3835) in the analyses of 4 samples of wine are quoted in 2 tables. Table 1 shows the close agreement in the sum of all organic acids of 2 wines as obtained on one

head by indirect detn. and calcn., on the other, by direct detn. Table 2 shows excellent agreement in the % and the nos. expressing the mode of combination in wine of tartaric, malic, lactic, succinic, acetic and tannic acids, when calcd. by the 2 entirely different methods of A. Quartaroli (cf. *C. A.* 5, 3316, 7, 1948) and of P. Dutoit and M. Duboux (cf. *C. A.* 7, 2082).

S. WALDBOTT.

Chemical analytical investigations on the ripening of grapes and on the formation of wine from them. W. I. BARAGIOLA AND CH. GODET. *Landw. Jahrb.* 47, 249-302 (1914).—A study was made in detail of the chem. changes which occurred during the ripening of grapes and in wine formation from the grapes. The results are given in tables and outlined graphically.

M. X. S.

The quantitative determination of lactic acid in wine. A. GASPARINI. *Stas. sper. agrar. ital.* 47, 752-73 (1914); *Chem. Zentr.* 1915, I, 509-10.—From an exhaustive study of the literature and on his own expts., G. draws the conclusion that lactic acid is a cleavage product of the malic acid present in normal wines and that, therefore, there must be a const. relation between the ext. content and the lactic acid content. The lactic acid results through the abnormal fermentation of the ext. substances under the influence of certain bacteria. The method of Möslinger was found most suitable for the quant. detn. of lactic acid in wines. This method is described in detail.

C. F. MILLER.

Rapid determination of total tartaric acid and of potassium in wines. A. KLING AND A. LASSIEUR. *Ann. fals.* 7, 410-6 (1914); through *J. Soc. Chem. Ind.* 34, 242 (1915).—Tartaric acid may be detd. by the following modifications of the racemate method (cf. *C. A.* 5, 2381; 6, 3382): 25 cc. of the wine are treated with 10 cc. of 2% NH_4 *l*-tartrate soln. and 20 cc. of a soln. of Ca acetate (16 g. CaCO_3 plus 120 cc. glacial AcOH per l.); after standing 30 min., the ppt. is collected on a filter, washed, dissolved in dil. H_2SO_4 , and the soln. titrated with KMnO_4 soln. The result is calc. to g. KH tartrate per l. of wine; 0.2 g. per l. is deducted from the amt. found as a correction for the *l*-tartrate occluded by the ppt. K is detd. by the perchlorate method. Under the conditions given, this method detcs. the K present as salts of organic acids and also as sulfate. The ash of the wine is treated with 10 drops of water and 10 drops of HClO_4 (56° Bé., d. 1.615), evapd. at 110° until most, but not all, of the HClO_4 has been driven off, the moist residue when cold is treated with 6 cc. 97% alc. containing 0.2% HClO_4 , the ppt. is collected on a filter, washed with 95% alc., washed into a crucible with alc.; the latter is evapd., and the residue heated to dull redness for 12 min. with 3 g. Na_2CO_3 , whereby the KClO_4 is converted into chloride. The mixt. is dissolved in water, 10 cc. 0.1 *N* AgNO_3 is added, followed by 5 cc. HNO_3 (36° Bé., d. 1.324), and 0.5 cc. ferric alum soln., and the excess of Ag titrated with 0.05 *N* thiocyanate soln. During the titration the sediment of AgCl should be disturbed as little as possible, since AgCl reacts to some extent with $\text{Fe}(\text{CNS})_3$.

P. B. DUNBAR.

The determination of potassium hydrogen tartrate and tartaric acid. H. ASTRUC. *Ann. fals.* 7, 416-7 (1914); through *J. Soc. Chem. Ind.* 34, 242 (1915).—The Kling racemate method (see preceding abst.) has been found to be the most trustworthy method known at present for the detn. of tartaric acid and its salts in a. drinks, fruit juices, etc. A detn. may be made in less than 1 hr. Its chief disadvantage is the cost of the reagent, NH_4 *l*-tartrate.

P. B. DUNBAR.

The alcohol-acid number and the judgment of wines. N. ZACHARIADES AND J. CZAK. *Z. landw. Versw.* 17, 869-85 (1914).—501 Austrian wines were analyzed and the alcohol-acid numbers according to Gautier and to Jeanprêtre calcd. and tabulated. Either calcn. gives results of much value, taken together with other tests, in the detection of diln.

L. J. GILLISPIE.

The limit numbers of the Swiss food code for minimum contents of non-volatile acids in wines. W. I. BARAGIOLA. *Schweiz. Apoth. Ztg.* 53, 166-7(1915).—N. Zachariades and J. Czak (preceding abstr.) applied the Swiss limits (Jeanprêtre nos.) to the analysis of 500 Austrian wines. With few exceptions, these nos. as well as the Gautier nos. were exceeded; hence these nos. do not seem to be too strict (except that the Gautier nos. are too high in certain cases and too low in others). Wines high in tartaric acid, *e. g.*, those of Styria, are favored by the Jeanprêtre nos. These nos. in connection with other data, furnish a good basis for the judging of wines in respect to the addition of H_2O . S. WALDBOTT.

Results of the official wine statistics of period 1912-1913. A. GÜNTHER. *Arb. Kais. Gesundheits.* 49, 1-467(1914); through *Chem. Zentr.* 1915, I, 444-7.—Unfavorable weather conditions and vegetable and animal pests were detrimental to the quality and quantity of the crop. Satisfactory results are reported in combating caterpillar of *Conchylis ambiguella*, with a soln. consisting of 0.75 kg. cottonseed oil soap and 1.5 kg. 10% nicotine soln., and also with a mixture of 0.75 kg. $CuSO_4$ -lime suspension and 1.5 kg. 10% nicotine soln. The total quantity (in the whole empire) of grape must was 1,004,947 hl. 995 wines and 5088 musts were examd. Results on sugaring wines were very favorable and confirmed the previously observed fact that the acid degradation in sugared wines mostly starts earlier than with natural wines, the reason apparently being due to slower settlement of yeast in sugared wines and to the reduction of acidity on diln. with sugar water. High acidity seems to retard acid retrogression. Numerous expts. proved that by proper cellar treatment (as warm storage, deacidification, re-fermentation, fining by isinglass) must from poor, nearly frozen grapes, yield a sound product, marketable without any admixture of higher grade wines. The widespread opinion that warm storing influences "Moselwines" unfavorably could not be verified. As to the proper time of deacidification, there are conflicting views of different investigators. In general it was found more satisfactory to effect deacidification (by means of pure $CaCO_3$) after fermentation. Among 509 white wines, 71% contained up to 0.11 g., 22% 0.12-0.16 g. and 6% 0.17 g. and more volatile acids. Red wines yielded more volatile acids; of 1893 examd., 93% contained up to 0.16 g., 3% 0.17-0.20 g. and 4% 0.21 g. and more. Among 662 foreign sweet wines, 88% contained up to 0.19 g. and 12% 0.20 g. and more volatile acids. For sulfuring wine barrels, solns. of SO_2 are preferred, insuring uniformity in the SO_2 content of wines, as well as for cellar-technical reasons. The great number of available data shows that growth of bacteria and the reproduction of molds and certain apiculatus-yeasts is sufficiently hindered by SO_2 . It is, however, not able to suppress the development of other ferments (*saccharomycodes* and *torulae*). The action of SO_2 is advantageously supported by an addition of pure culture yeast acclimatized to SO_2 . The H_2SO_4 content of wines is materially increased by storing in excessively sulfured and insufficiently washed vessels. There are different opinions as to the form in which H_2SO_4 is present in wine. According to physicochem. views, it is present in the form of secondary sulfates. Small amts. of H_2SO_4 are able to change greatly the character of a wine. It is demanded that native wines (white as well as red wines) are to be objected to if their H_2SO_4 content exceeds 2 g. K_2SO_4 per l. In a great number of 1912 wines the presence of citric acid was verified. Denigé's reaction for citric acid has only the value of a preliminary test, as a positive is not conclusive. Stahre's reaction (*C. A.* 9, 687) and also the identification of citric acid by means of its Ca salt are recommended as reliable. As to malt wines they show the following compn: 5-7.5 g. alc., 1.5-2.2 g. ext., 0.1-0.2 g. sugar and 0.3-0.6 g. acids per 100 cc. They resemble German white wines in their compn., but are easily distinguished by their dextrin content and the absence of tartaric acid.

I. W. HAAS.

Photomicrography applied to biometry with special reference to differentiation between yeasts employed in practice. P. LINDNER. *Wochschr. Brau* 31, 469-71 (1914).—Mensuration of dimensions of microorganisms by means of the micrometer is a tedious task; furthermore, the results are only approximate estns. in case of continually moving organisms. With more convenience and a higher degree of accuracy measures may be taken from photomicrographs provided they have been taken at definite enlargements. It was found that a photomicrograph of slowly moving cells is obtained sufficiently sharp for a linear enlargement of 500, if the time of exposure is 0.02 sec. (using intense light). L. succeeded in finding a more simple expression for the size of yeast cells. Instead of measuring a large number of single cells to obtain av. values, the cells are counted out which are required to fill completely a definite surface taken as unity. For a successful application of this biometric method the mounting of the slide plays an important role. The cells have to lie in one plane filling all interstices as completely as possible. Yeasts having sticky cell membranes must be made "dusty" by means of dil. acid or NaOH. The latter is to be added gradually in the presence of sufficient water and under rapid stirring to avoid changes in the structure of the cells. It is advisable to surround the cover glass by a ring of vaseline or wax to prevent flows in the liquid. A convenient linear enlargement for taking photomicrographs of yeast cells was found to be 500 (for bacteria 1000) and as a unit of surface is suggested the customary glass slide (26 by 76 mm.). L. proposes the term "surface number" (Flächenzahl) for the number of single cells contained in the area taken as unity. This surface number is rather characteristic for the different types of yeast (yeast D gave 136, y.U = 156, y.M = 180, y.K = 206) and with the same type deterioration due to changes in the nutrient medium may easily be detected.

L. W. HAAS.

Investigations on hops. V. On the aroma of hops. J. SCHMIDT. *Compt. rend. Lab. Carlsberg* 11, 149-63 (1915).—In all districts where the male hops have not been entirely eradicated, large stocks of hops will, in the long run become adulterated. Among the hop plants cultivated in the exptl. garden of the Carlsberg Laboratory, there were in 1911 two American plants ("Oregon Cluster" and "New York Spaulding English Cluster"), the hops of which exhibited a very peculiar, turpentine-like aroma, so widely different from that of all European varieties, that a single hop could at once be recognized by the smell among hundreds of others. Cultivation expts. made during 1911-4 showed that this aroma remained apparently constant in the foreign climate in these two plants and their cones. Crossing expts. with the two American plants and Danish males showed that the turpentine-like aroma was transmitted to between 0.5 to 0.75 of the offspring plants. From these expts. (and several others) it would seem that the aroma of hops is not so "volatile" a character or so entirely due to purely local conditions as has generally been believed.

L. W. HAAS.

Use of sugar in the brewery. E. JALOWETZ. *Brau.-Malsind.* 16, 59-61 (1915).—If beet sugar is to be used as partial malt adjunct, J. recommends (in order to be independent of variations in the activity of invertase) its use as invert sugar, which can easily be prepd. in the brewery as follows: Dissolve the required amt. of sucrose in a corresponding quantity of water (400 l. per 200 kg. sugar) at 60-65°, add to this soln. (the temp. of which should not exceed 55°) the requisite quantity of yeast (8 kg. thick yeast per 200 kg. sugar), and allow to stand for 4 hrs. at 50-5° with occasional stirring. This invert sugar soln. together with the yeast is directly added to the b. wort.

L. W. H.

Ferments of rum. E. KAYSER. *Compt. rend.* 160, 408-11 (1915).—The compn. of rum (and tafia) depends upon the nature of the raw material (sugar cane juice and its derivs.), mode of fermentation and distn. and especially on the microorganisms which effect the transformation of the saccharin matter. The difference in the action of bottom-fermenting yeasts and schizosaccharomyces may be more accentuated by an addition of wine to the molasses soln. to be fermented. Characteristic for the latter organisms when acting in a sterilized medium, is a depression of the production of volatile acids, aldehydes and higher alcs., reducing the non-alc. coeff. by 50%. Addition of mineral or amino N favors especially the schizosaccharomyces, at the same time diminishing their capacity of producing volatile acids, while the reverse takes place with bottom-fermenting yeasts. When sterilized molasses-must was fermented by a rum yeast alone and by the same yeast in association with a microbe isolated from the must, the non-alc. coeff. was doubled in the latter case, due to an enormous increase of volatile acids under simultaneous feeble aldehydification. Addition of weak wine, yeast ext., or leucine augmented the non-alc. coeff. while diln. of the must diminished it; furthermore, the type of yeast employed causes notable variations. A remarkable result was obtained by the combined action of a bottom-fermenting and a film-forming yeast frequently met with in sugar cane sap. The non-alc. coeff. was about 5 times that attained with the former yeast alone. All components were augmented, notably the esters (from 55.4 to 1320 mg. per 100 g. abs. alc.). The judicious application of pure yeasts, therefore, will procure rum products of const. compn. and enable the manufacturer to produce more or less ethereal products to satisfy the demand.

L. W. HAAS.

The spirits and spirits preparations industries in the year 1913. A correction. H. RÜDIGER. *Chem. Ind.* 38, 121 (1915).—A correction of a reference given in complete report (cf. *C. A.* 9, 1221).

F. W. SMITHER.

Laboratory experiments in relation to employment of sucrose in distilleries. W. BÜCHLER. *Z. Spiritusind* 38, 98 (1915).—B.'s expts. show the possibility of satisfactory final fermentation of mashes, the fermentable exts. of which are derived at about equal parts from potato mash and cane sugar, resp., provided that such compound mashes receive an addition of yeast nutrient. A good nutrient is thick brewers' yeast-waste liquefied by heating it to 56-62°, followed by short boiling. A still better nutrient is obtained by protein degradation. Brewers' yeast is warmed in a wooden vessel to about 60° for 1 hr., then 5 cc. com. HCl per l. yeast added, the mixt. kept at 60° for 12 hrs., finally warmed up to 81°, cooled and 10-15 cc. CH₂O per l. added. If kept under air-tight closure, this nutritive ext. is very stable.

L. W. HAAS.

Nipa palm swamps in the Philippines as sources of alcohol. *Chem. Trade J.* 56, 169 (1915).—There are over 100,000 acres of Nipa palm swamp available, of which about 90% has never been touched. It is estd. that the Nipa sap available would yield 50,000,000 gal. of alc. fuel every season (at a cost of about 14 c. per gal., if a modern distg. plant is installed). The total production of alc. in the Philippines is approx. 2,500,000 gal. per season, 0.9 of which is made from Nipa sap. Only 2% of the alc. now produced is denatured for com. use.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

The essential oil of *Scherungulu tubers*. ANON. *Bull. Imp. Inst.* 13, 15-6 (1915).—Tubers of *Kaempferia ethalae*, J. M. Wood, yielded 2% of (1) a light volatile oil (d_{15}^{25} 0.9437, $[\alpha]_D^{25}$ +19° 47', acid no. 2.3, ester no. 5.0, ester no. after acetylation 47.6), contg. terpenes, linalol, esters and a new ketone (not described), and (2) a heavy oil consisting of the ketone found in the light oil and liquid constituents, probably sesquiterpenes.

L. G. C.

Investigations of vegetable drugs and poisonous plants. ANON. *Bull. Imp. Inst.* 13, 28-65 (1915).—The article gives results of the chem. investigation and the value as sources of drugs of a number of plants from various countries. Those of importance are *Podophyllum emodi* from India and the Egyptian *Hyoscyamus muticus*, a valuable source of atropine.

L. G. C.

Lime and lemon as sources of citric acid and essential oils. W. R. DUNLOP. *Bull. Imp. Inst.* 13, 66-87 (1915).—Methods of cultivation, yields, profits and chem. compn. of the two are compared. The figures indicate that the lime is richer in juice, citric and phosphoric acids and possesses anti-scorbutic properties, while the lemon contains more essential oil. Lemons may be regarded as yielding 634 lb. of citric acid and 88 lb. of essential oils per acre as against 914 lb. and 65 lb., resp., for limes.

L. G. C.

Liquor kalii arsenicosi. O. RICHTER. *Apoth. Ztg.* 29, 962-3 (1914).—A slight change in detail is suggested in the Ger. Pharm. procedure, namely, the heating of the aq. soln. of KHCO_3 for some time prior to the addition of As_2O_3 .

W. O. E.

Bolus alba sterilisata. ERNST RICHTER. *Apoth. Ztg.* 29, 978.—Suggestions are made for improving the Ger. Pharm. requirements for this product.

W. O. E.

The examination of tablets. J. HERZOG. *Apoth. Ztg.* 30, 19-20, 24-5 (1915).—Four samples were examd., morph. hydrochloride, bromum compositum, phenacetinum compositum and ext. cascarae sagradae. The procedures followed were: (1) *Morph. hydrochloricum*. Triturate 20 tablets in a mortar and wash the powder quantitatively into a flask with hot alc. Ext. repeatedly with boiling abs. alc., filter and evap. to dryness. Dissolve the residue in about 5 cc. hot H_2O and transfer quantitatively by means of an additional 5 cc. H_2O to a 100 cc. glass-stoppered Erlenmeyer, add 3 drops 10% NH_4OH , shake vigorously 10 min. and set aside 12 hrs. Pass the liquid through a small, smooth suction filter, allowing the flask to drain completely, then dry both flask and filter at 100°. Dissolve the morphine crystals in 10 cc. 0.1 N HCl , pour the soln. into a 200 cc. flask, carefully rinsing with H_2O the filter and glass vessels used, then increase the vol. of liquid to about 100 cc. and titrate under a layer of Et_2O with 0.1 N KOH , using iodoeosin as indicator. Very satisfactory results were obtained by this method. (2) *Bromum compositum*. After weighing several tablets, dissolve one with H_2O in a 250 cc. tared flask, fill to mark and apply a portion of the liquid to tests for sulfates and carbonates. In a 50 cc. aliquot det. the Br volumetrically in accordance with the Ger. Pharm. procedure, using K_2CrO_4 as indicator. In a 2nd aliquot, det. the halogen gravimetrically by pptn. with AgNO_3 . Results are good. (3) *Phenacetinum compositum*. Weigh out an amt. of the powdered sample equal to 4 tablets and ext. repeatedly with boiling abs. alc., receiving the solvent in an evapg. dish and evapg. to dryness. After disintegrating the residue with a glass rod, moisten with very little H_2O , then add 30 g. H_2O and stir for some time. Transfer the mixt. to a small, smooth filter, washing with four 5 cc. portions H_2O . Dissolve the residual phenacetin remaining in the dish and on the filter in hot alc. Evap. to dryness and

weigh as phenacetin (major portion). Transfer the aq. liquid to a separatory funnel, render slightly acid and ext. with about 30 cc. Et_2O . The ethereal soln. yields on evapn. an additional quantity (minor portion) of phenacetin. After rendering the aq. liquid alk., ext. repeatedly with CHCl_3 in order to recover the caffeine. (4) *Ext. cascarae sagradae*. Heat 1 tablet in 100 g. H_2O until the extractives are dissolved and the inert excipients subsided. Pass through a filter and ext. 10 cc. in a test tube with 10 cc. Et_2O for a period of 2 min. Pour off 3 cc. of the clear (should be intensely yellow) supernatant liquid into a second test tube and add an equal vol. of 5% NH_3 , shaking the mixt. thoroughly, whereupon a deep coral-red color should appear (so-called emodin test). Dil. 2 pts. of the original aq. soln. with 18 pts. H_2O and treat 10 cc. of the resulting liquid in exactly the same manner as above, whereupon the Et_2O soln. should be faintly yellow and the ammoniacal soln. distinctly coral-red after shaking. This method is applicable to sugar-coated tablets as well.

W. O. E.

Papayans bell. C. MANNICH. Univ. Goettingen. *Apoth. Ztg.* 30, 37-8(1915).—According to the analytical findings, the prep. consists of 0.022 g. charcoal of low adsorption capacity, 0.278 g. NaHCO_3 per tablet in addition to oil of gaultheria. No proteolytic enzyme of the nature of papain could be detected.

W. O. E.

Papayans bell. L. LEWIN. *Apoth. Ztg.* 30, 38(1915).—Comments are made on the results obtained by M. (cf. preceding abstr.). Attention is directed to the fact that papain under certain conditions suffers deterioration very rapidly, from which the inference is clear that the sample under investigation may originally have contained the enzyme in appreciable quantity.

W. O. E.

Salicol. C. MANNICH. Univ. Goettingen. *Apoth. Ztg.* 30, 43(1915); cf. C. A. 8, 1639, 3094.—According to M., this prep. is a mixt. of 85% acetoxybenzoic acid, 14.5% decompn. products of acetoxybenzoic acid and 0.5% citric acid, in contradiction to the mfrg.'s claims that the prep. consists of "Acid aceto-citrylo-salicylic."

W. O. E.

Applied plant microchemistry. X. The microchemical detection of lapachol. O. TUNMANN. *Apoth. Ztg.* 30, 50-2(1915).—The easy and certain detection of lapachol is shown by means of the sublimation method.

W. O. E.

Preparation of alkoxymethyl ethers of morphine. C. MANNICH. *Apoth. Ztg.* 30, 56 (cf. D. R. P. 280,972).—The process consists essentially of interaction between the alkali compds. of morphine and halogenated methyl alkyl ethers of the general formula: XCH_2OR . It is claimed for the methoxymethyl ether of morphine, for example, that it deadens the sense of pain more than the known ethers of morphine but less than morphine itself; that it possesses the advantage of not being a habit-forming drug; that the active and toxic doses lie very far apart.

W. O. E.

Determination of silver in colloidal silver preparations. P. W. DANCKWORTT. Univ. Breslau. *Arch. Pharm.* 252, 497-501(1914).—In the case of collargol and similar preps. containing chlorides, the method of Lehmann (C. A. 8, 2217) was found reliable, while that of Stoecker (C. A. 8, 3613) gave unsatisfactory results. In the present paper, the following procedure is recommended for protargol. Dissolve 1 g. of the sample in 10 cc. cold H_2O contained in an Erlenmeyer, to which is added, under constant agitation, a mixt. of 5 cc. perhydrol and 15 cc. 25% HNO_3 (the mixt. employed by Jannasch, i. e., equal vols. of a 15% H_2O_2 and HNO_3 of sp. gr. 1.4 is equally effective). Warm the flask $\frac{1}{2}$ - $\frac{3}{4}$ hr. on the water bath under the hood, agitating the mixt. from time to time, until only about 5 cc. liquid remains. Dil. with H_2O to 100 cc. and titrate the yellowish soln., after adding 10 cc. Fe NH_4 sulfate soln., with NH_4CNS . This method is not applicable to collargol and other preps. containing chlorides in appreciable amt.

W. O. E.

Poisonous woods. H. MATTHES AND E. SCHREIBER. Univ. Jena. *Ber. pharm.* Ges. 24, 385-444 (1914).—The investigation was confined to the following woods: Royal teak or Moah wood (*Illipe longifolia* or *I. latifolia*); Teak (*Tectonia grandis*); Teak (*Flindersia australis*); Lapacho wood (*Tecoma araliacea*) and Greenheart wood (*Bignonia leucoxylon*). (1) Royal teak or Moah Wood contains 0.7% lapachonone, $C_{18}H_{16}O_4$, m. 61.5°, heretofore reported only in lapacho wood by Crosa and Manuelli (*Atti accad. Lincei* (5) 4, II, 250-35 (1893)). It yields the *picrate*, $C_{18}H_{16}O_4 \cdot C_6H_5O_7N_3$, m. 133°. Further, yellow crystals of lapachol, $C_{18}H_{14}O_4$, to the amt. of 0.1%, heretofore reported only in lapacho wood by Paterno (*Gazz. chim. ital.* 1882), also by Stein (*Jahresb. d. Chem.* 1866) in greenheart wood. In addition, 3 resins were isolated: an Et_2O -sol. variety (a) 0.76%, I no. 62.51, sapon. no. 122, acid no. 86.00, ester no. 39.20; $CHCl_3$ -sol. (b) 1.03%, I no. 82.71, sapon. no. 126, acid no. 49, ester no. 77; and alc.-sol. (c) 3.35%, I no. 73.04, sapon. no. 92.40, acid no. 42, ester no. 50.40. The poisonous effects are due neither to lapachol nor lapachonone but rather to the resins, of which the alc.-sol. variety is the least toxic. No glucoside, glucosin or alkaloid was detected in this wood. The following tests were applied in the recognition of Moah wood: (a) *Lapachol test*: On the application of about 0.1 N KOH, small cherry-red dots appear on the surface; (b) *Lapachonone test*: If one of the colorless crystals from the woody tissues be placed on conc. H_2SO_4 , an intense indigo blue color results. (2) *Tectonia grandis* (Teak wood, Djati): While Romanis (*Chem. Soc.* 51, 1887) reports the presence of tectoquinone in this wood, none was found in the present instance. In addition to a little oil and a hydrocarbon of the formula $C_{24}H_{28}$ —2, 3 resins were isolated by fractional treatment with solvents, characterized as follows: Et_2O -sol. (a) 0.55%; $CHCl_3$ -sol. (b) 1.15%, Huebl I no. 136.5, sapon. no. 243.5, acid no. 109.6, ester no. 133.9; alc.-sol. (c) 2.93%, I no. 60.7, sapon. no. 106.4, acid no. 90.7, ester no. 15.7. All 3 resins produce dermatitis accompanied at intervals by intense itching. Lapachol and lapachonone were not detected. (3) *Flindersia australis* (native teak, Moah wood not identical with that first described) contains, in addition to a resinous oil, resins separable by fractional extn. Resin oil 6.07%, I no. 34.93, sapon. no. 78.40, acid no. 0.00, ester no. 78.40; Et_2O -sol. resin 7.40%, I no. 38.70, sapon. no. 95.20, acid no. 50.80, ester no. 44.40; $CHCl_3$ -sol. resin 3.36%, I no. 90.61, sapon. no. 95.20, acid no. 13.48, ester no. 81.72; alc.-sol. resin 2.83%, I no. 93.10, sapon. no. 78.40, acid no. 29.79, ester no. 48.61. An alkaloid *flindersine*, $C_{22}H_{28}O_7N_3$, m. 182–3°, was obtained. It is insol. in H_2O , sol. in $CHCl_3$, a.c., C_6H_6 , AcOH, HCl, H_2SO_4 , caustic alkalies, glycerol, paraffin and fatty oils, difficultly so in petroleum benzene. It is optically inactive, unites with Br to yield the *addition-product*, $C_{22}H_{28}O_7N_3Br_2$; with picric acid and $PtCl_4$ to form cryst. salts, and with the usual alkaloidal reagents to yield ppts. None of the constituents isolated from this wood were found to irritate the skin or otherwise possess toxic properties. (4) Lapacho wood contains 0.26% lapachonone and 1.93% lapachol in addition to resins which in contact with the skin produce mild irritation and are characterized as follows: Et_2O -sol. 0.91%, I no. 108.50, sapon. no. 252.00, acid no. 74.48, ester no. 177.52; $CHCl_3$ -sol. 2.33%, I no. 109.10, sapon. no. 134.40, acid no. 44.68, ester no. 89.72; alc.-sol. 8.56%, I no. 101.70, sapon. no. 173.60, acid no. 35.56, ester no. 138.04. Petroleum-benzene-sol. ext., amounting to 3.29%, produces no irritation when brought into contact with the skin; the other 3 exts. produce a marked reddening of the skin but no itching sensation, the inflamed localities healing completely after 6 days. (5) *Tecoma araliacea*. This very hard and heavy wood contains, in addition to 7.64% lapachol, resins separable by fractional extn. and capable of producing intense itching and inflammation of the skin, being characterized as follows: Et_2O -sol. portion 1.49%, I no. 97.53, sapon. no. 98.00, acid no. 25.20, ester no. 72.80; $CHCl_3$ -sol. portion 1.55%, I no. 99.40,

sapon. no. 119.00, acid no. 31.50, ester no. 87.50; alc. sol. portion 5.02%, I no. 98.96, sapon. no. 56.00, acid no. 25.20, ester no. 30.80. (6) Greenheart wood contained 3.69% lapachol and resins separable by fractional extn. They are characterized as follows: Et_2O -sol. 3.67%, I no. 79.22, sapon. no. 140.00, acid no. 32.76, ester no. 107.24; CHCl_3 -sol. 1.32%, I no. 88.75, sapon. no. 196.00, acid no. 29.68, ester no. 66.32; alc.-sol. 5.92%, I no. 88.58, sapon. no. 106.40, acid no. 23.80, ester no. 82.68. The toxic properties of the woods examd. are shown to be due to resins contained therein, more particularly to the content of the latter in free unsatd. resin acids. It should be noted in this connection that all wood derived from the Bignoniaceae, to which likewise the *Tecoma* and *Illipe* belong, contain, in addition to lapachol or lapachonone, or both together, resins which are in greater or less degree skin irritants. The assumption that the former substances, which are sol. in resins and oils, stand in genetic relation to the resins themselves appears to be unwarranted. W. O. E.

The artificial resin "albertol" as a substitute for mastic. G. MAUR. *Pharm. Ztg.* 59, 876 (1914).—This new product is shown to have the following properties: d_{15}^{20} 1.0420, m. 56–9°, $[\alpha]_D^{20}$ +38.05, acid no. 22.72, ester no. (calcd.) 44.88, sapon. no. 67.60, loss of wt. at 100° 1.03%, mineral constituents 0.05%. A 5% soln. in a 200 mm. tube gave a rotation of +3.4°. W. O. E.

Partially neutralized resin solutions. KARL DIETERICH. *Pharm. Ztg.* 59, 937–8 (1914).—A soln. of colophony (200) in a mixt. of turpentine (100) and benzene (700) is treated with dry powd. NaHCO_3 , previously triturated with benzene, then dild. to 1000 cc. and filtered. The product is recommended as a substitute for mastic. W. O. E.

A note on compressed tablets. S. BERTHA MÜLLER. *Am. J. Pharm.* 87, 197–8 (1915).—A brief discussion of the use of white dextrin as a diluent and disintegrator both for compressed tablets and tablet triturates. W. G. GARSSLER.

Remarks on digitalis. WILLIAM C. ALPERS. *Am. J. Pharm.* 87, 210–20 (1915).—A review of the pharmacy and chem. of digitalis and its physiol. tests. W. G. G.

Review of therapeutic novelties discovered in 1914, including specialties and secret remedies. S. RABOW. *Chem. Ztg.* 39, 211–2, 241–2, 254–5, 263–5 (1915). E. H.

Review of recent work on perfumes and ethereal oils. S. FACHINI. Milan. *Ann. chim. applicata* 3, 181–97 (1915). S. LEVY.

Preparation of sirup of iron calcium lactophosphate. A. C. BARBANO. Turin. *Giorn. farm. chim.* 63, 105–7 (1914).—Prepare 2 solns. composed resp. of (1) 9.25 g. cryst. FeSO_4 in 350 g. distd. H_2O and (2) 22.75 g. NaHPO_4 in 159 g. distd. H_2O ; mix these solns., collect the ppt. on a filter, wash, allow to drain until the wt. does not exceed 100 g. and dissolve in 14 g. conc. lactic acid. Prepare another soln. composed of 13.30 g. tricalcium phosphate, 24 g. conc. lactic acid and 100 g. H_2O . Add this soln. to the final soln. above with the addition of sufficient H_2O to make 388 g., filter and add 625 g. white sugar and 15 g. alc. soln. of lemon oil. This prepn. on standing was observed to deposit a cryst. ppt. which proved to be CaSO_4 . The occurrence of this ppt. is explained by the fact that the Na_2SO_4 produced by the reaction of solns. (1) and (2), when not completely removed from the ppt. (also produced by this reaction), reacts with $\text{CaH}_2(\text{PO}_4)_2$ to form CaSO_4 . The sucrose of the sirup is

also inverted by the excess acid of the soln. and a portion of the glucose of the invert sugar is gradually deposited by crystn. As a modification of the original method, B. proposes that the ppt. produced by the reaction of solns. (1) and (2) be washed with distd. H_2O until the filtrate no longer reacts with $BaCl_2$, and H_2O sufficient to make 300 g. instead of 388 g. be added to the soln. before the addition of sugar; the amt. of sugar is reduced from 625 g. to 585 g. and 100 g. neutral glycerol (31°) are added with the sugar. Otherwise the formula remains the same.

H. S. PAINE.

Benzene as a substitute for ethyl alcohol in the preparation of tincture of iodine. ITALO CEPPELLINI. Pontremoli. *Boll. chim. farm.*, 53, 660(1914).—In order, to test the resp. merits of $EtOH$ and C_6H_6 in the prep. of tincture of I, C. prepd. a soln. with each solvent according to the Italian pharmacopeia (2 g. I in 18 g. of C_6H_6 or 95% $EtOH$). The I crystd. from the C_6H_6 soln. in a short time, when the latter was placed in a large glass container at a temp. of 5° . After standing 48 hrs. in open Erlenmeyer flasks (24° and 763 mm.) the C_6H_6 and $EtOH$ solns. lost 6.065 g. and 2.015 g., resp., in wt. In addition to the above disadvantages of C_6H_6 the odor of the latter was also found to be objectionable. The presence of HI in $EtOH$ solns. of I may be successfully obviated by employing Gaglio's suggestion, i. e., by the addition of 1.1% of HIO_3 , which reacts with HI to form I and H_2O .

H. S. PAINE.

Bromotannic sirup. G. DE RIDDER. *J. pharm. Anvers; Boll. chim. farm.* 53, 663(1914).—Dissolve 2 g. tannic acid in 25 cc. hot distd. H_2O ; to the cold soln. add 2 g. Br in 100 g. H_2O and immediately add sufficient simple sirup to make 1 kg., with further addition of 2.5 g. aromatic tincture, 1.25 g. tincture of vanilla and 4 drops $AcOEt$.

H. S. PAINE.

The use of large doses of morphine as an analgesic in obstetrics and surgery. G. BERTRAND. *Bull. sci. pharmacol.* 21, 497-501(1914).—An exam. was made of a prepn. of morphine recently used by Ribemont Dessaignes in the Paris hospitals as an analgesic in childbirth. The prepn. was reported to be produced by the action of an enzyme, such as that of yeast or papaw, on a morphine salt. It was claimed that the prepn. was only about $1/15$ as toxic as morphine-HCl. B. found the prepn. to be a soln. of morphine-HCl contg. 3.24% of the pure salt. In its physical consts. and its action towards the various alkaloidal reagents, the alkaloid present was found to be identical with morphine. The toxicity of the prepn. was also found to be the same as that of a soln. contg. an equal amt. of morphine-HCl. A 3.24% soln. of morphine-HCl was given to five women in childbirth in the same dose as it is directed that the above prepn. be used, i. e., $1\frac{1}{2}$ cc. contg. 0.0486 g. morphine-HCl and a very similar action was noted. Thus a profound anesthesia can be obtained successfully by the judicious use of a relatively high dose of morphine, but there is always danger of blue babies, though as a rule they are easily resuscitated.

B. H. ST. JOHN.

The stability of morphine in presence of putrefaction. F. DOEPMANN. Breslau. *Chem. Ztg.* 39, 69-71(1915).—Separate quantities of 1 kg. of chopped, lean horse flesh were mixed with 200, 100, 50 and 20 mg., resp., of morphine-HCl and 200 g. of the mixt. investigated after 1, $2\frac{1}{2}$, $5\frac{1}{2}$, and 11 months. The putrefying mass was thoroughly extd. with very dil. $AcOH$, first cold, then warm, and finally on the water bath. The acid ext. was concd., pptd. with alc., the alc.-free filtrate pptd. with $(AcO)_2Pb$, excess of Pb removed by H_2S and the soln. concd., made alk. with NH_4OH , and extd. repeatedly with warm $CHCl_3$. The residue from the $CHCl_3$ ext. was dissolved in dil. H_2SO_4 and extd. with pure amyl alc. to remove coloring matters, then made alk. with $NaOH$, and extd. with a small amt. of $CHCl_3$ to remove ptomaine bases, and finally made alk. with NH_4OH and repeatedly extd. with warm $CHCl_3$. The pale yellow varnish left on evapg. the $CHCl_3$ gave in every case the characteristic reactions of morphine.

F. W. SMITHERS

Synthetic camphor and its detection in official camphor. HEFFTER; LANGGAARD; BOHRISCH. *Apoth. Ztg.; Pharm. Zentralhalle* No. 50; H., *Schweis. Apoth. Ztg.* 53, 101-2(1915).—Unless synthetic camphor is free from impurities, *e. g.*, pinene-HCl, camphene, borneol, and until expts. on animals (by Langgaard and others) shall have been extended to man, internal and subcutaneous uses of synthetic camphor should not be considered. Bohrisch, in reexamg. the official tests for true camphor, substitutes the following for Lenz's test: To 0.1 g. of powdered camphor in test tube is added 2 cc. of a 1% vanillin-HCl soln., and the mixt. put into a beaker with water which is warmed gradually. At 30° the color is yellow, at 60° bluish green, at 75-80° indigo-blue. The latter color persists for several hrs. even after cooling. Synthetic camphor by the same treatment gives only a yellow color. Vanillin-HCl-H₂SO₄ gives still better results. The best identity test is that of optical rotation, official camphor being +, synthetic inactive.

S. WALDBOTT.

Incompatibility of tincture of iodine and mercuric chloride solution. L. REUTTER. *Bull. sci. pharm.* 1914, 463; *Schweis. Apoth. Ztg.* 53, 107(1915); *Pharm. J.* 94, 357 (1915).—Now that tinct. of I is so widely used as a first aid disinfectant for wounds, the danger of applying HgCl₂ dressings afterwards is pointed out. The strongly irritating HgI₂ is formed in such a case. To remove it, wash the wound with 1:10 KI soln.

S. WALDBOTT.

New method of making syrupus hypophosphitum U. S. P. and syrupus hypophosphitum compositus, U. S. P. F. A. UFAHER SMITH. *Midland Druggist* 49, 193(1915).—To avoid in these preps. the use of 5 different hypophosphites, 2 of which are deliquescent, 2 new formulas are proposed, based on the interaction of the Ca salt with the sulfates of K, Na, Fe⁺⁺⁺ and Mn.

S. WALDBOTT.

"Salvarsansodium." WECHSELMANN. *Münch. med. Wochschr.* No. 6, 1915; Fleissig, *Schweis. Apoth. Ztg.* 53, 137-9(1915).—This is the di-Na salt of salvarsan, a yellow powder, sol. in H₂O with alk. reaction, contains about 20% As. 0.1 g. salvarsan corresponds to 0.15 g. "salvarsansodium." In air it turns brown, becomes insol. and more toxic. It is intended to replace neosalvarsan.

S. WALDBOTT.

The British pharmacopeia 1914, as it affects officinal pharmacy. J. P. GILMOUR. *Pharm. J.* 94, 202-5(1915).—A detailed criticism of the changes made, and the relation of a great many pharmaceutical preps. to the various legislative acts is pointed out.

S. WALDBOTT.

Alkaloids, chloroform and opium preparations of the British pharmacopeia. D. B. DOTT. *Pharm. J.* 94, 206(1915).—Criticisms are made on these subjects.

S. W.

The British pharmacopeia 1914, with special reference to the limit tests for arsenic and lead. J. F. TOCHER. *Pharm. J.* 94, 207-8(1915).—The dual, semi-equiv. use of the imperial and the metric systems of wts. and measures in stating doses is deprecated. To test for Pb, render the filtered soln. of the sample alk. with NH₃ and add 1 cc. of KCN (to prevent pptn. of Cu). The amt. of standard Pb soln. necessary to add to a control soln. so as to produce the same depth of color as that found upon adding Na₂S, measures the amt. of impurity present. Limits are given for Na, K, NH₄, Mg and Cu salts and the chief acids of the Brit. Pharm. The test for As is a modified Gutzeit test, *i. e.*, forming of a yellow stain on HgCl₂ paper if As is present. To prevent interference by H₂S, paper satd. with Pb(AcO)₂ is interposed. The use of SnCl₂ reduces any As to As⁻⁻⁻. The amt. of As allowed in tartaric acid is 1.4:1,000,000, in many other compds. 5:1,000,000, in reduced Fe 200:1,000,000. The influence of errors of observation is recognized.

S. WALDBOTT.

Notes on chemical nomenclature of the British pharmacopeia 1914. WM. B. COWIE. *Pharm. J.* 94, 236(1915).—Improvements in Latin titles are suggested. The

treatment of "characters and tests" for fixed oils and essential oils is generally commended. Exceptions are noted, also regarding "syrops." S. WALDBOTT.

The new (British) pharmacopeia: A few general criticisms. THOMAS STEPHENSON. *Pharm. J.* 94, 236-7(1915).—The inclusion of Indian drugs, *e. g.*, betel leaves, is objected to. The nomenclature of certain synthetics and other compds. is not well chosen. Tinct. of *nux vomica* is only $\frac{1}{2}$, the former strength, yet the dose remains the same. The book marks an advance, but bears evidence that the coöperation of pharmacists was not secured. S. WALDBOTT.

Notes on the British pharmacopeia 1914. FRASER McDIARMID. *Pharm. J.* 94, 237-9(1915).—The subjects discussed are recognition of pharmaceutical research, active principles, rejected and new drugs, assay processes and the principle of limits. Over-strength powdered exts., *e. g.*, belladonna, should be dild. with powdered leaves, not milk sugar, etc., making due allowance for the alkaloid in the leaves. S. W.

A discussion on the new British pharmacopeia. *Pharm. J.* 94, 244-6(1915). I. HENRY STOUT. *Materia medica* of the new pharmacopeia. II. DAVID MURRAY. Notes on the Br. Pharm. 1914. III. J. TAIT. Ether solubility of citric acid. IV. J. R. HILL. The British pharmacopeia 1914. V. J. A. FORREY. Comments on the Brit. pharm.—(I) Physiol. standards are wisely excluded. For belladonna root and henbane leaves, alkaloidal standards should be given. No distinction is made between Barbados and Socotrine aloes, and a test for Cape aloes as adulterant should be given. The additions to the chem. *materia medica* are summarized. (II) The subjects acetum scillæ, acid. carbol. liqu., collodium vesicans, lin. camphoræ, syr. ferri iodidi, tinct. capsici, tinct. hyoscyami, ung. acid. boric., ung. pot. iodid. are discussed. (III) The Br. Pharm. should state that solubility of citric acid in Et_2O (d. 0.720) is 1:40; tartaric acid is slightly sol. in Et_2O . (IV) The demanded absence of Fe in citric acid is not found in practice. Since the tannin in cinnamon bark ppts. alkaloids, flavoring tincts. should be made with the *essential oils*, *e. g.*, of caraway, cinnamon and cardamoms. (V) In the place of the terms decimil, centimil, 0.1 or 0.01 mil. should be used. For liquid ext. of cascara and others, repercolation should be practiced. S. WALDBOTT.

Some medico-legal aspects of the new British pharmacopeia. H. W. GADD. *Pharm. J.* 94, 272(1915). S. WALDBOTT.

Some notes on the new British pharmacopeia. H. H. JONES. *Pharm. J.* 94, 272-3(1915).—An extended discussion of the changes from the 1898 edition. Many exts. have disappeared. Confusion may arise from replacement of the green exts. of henbane and belladonna by dry powdered exts. from the leaves, standardized to contain 0.3 and 1% alkaloids. S. WALDBOTT.

Acidity of hydrogen peroxide solution. J. S. WHITE. *Pharm. J.* 94, 316(1915); cf. *C. A.* 8, 2600.—Four samples came well within the limit for acidity set by Brit. Pharm. 1914 (direct titration method), but the same samples showed notably higher acidities by the U. S. P. method (previous evapn. in alk. soln.), 1 being above the limit, which is alike in both pharmacopeias. The method of Murray (*C. A.* 8, 2453) applied to 1 sample gave a result which agreed with that by the U. S. P. method. S. WALDBOTT.

Acidity of hydrogen peroxide solution. THOS. CALLAN. *Pharm. J.* 94, 413 (1915); cf. preceding abstr.—When 4 samples were tested by the Brit. Pharm. direct titration method using Me orange, the results were almost the same as when tested by the evapn. method of the U. S. P. when the same indicator was used. When phenolph. was used on the same 4 samples, the results were again almost alike by both methods, but considerably higher than the results with Me orange, and in all cases exceeded the limit of 2.5 cc. 0.1 *N* KOH per 25 cc. H_2O_2 . Hence detns. of acidity give widely

varying results according to the indicator used (Me orange in Brit. Pharm., phenolph. in U. S. P.). The cause often lies in the Na_2HPO_4 observed in the evapn. residue. This, in presence of mineral acid, is acid to phenolph., but neutral to Me orange; hence the higher results in the former case. The U. S. P. method, in addition, has several sources of error; decompn. of traces of NH_4Cl , also of AcNHPh by alkali; and possible absorption of CO_2 during evapn., especially if this is done in an open basin instead of a flask.

S. WALDBOTT.

The use of salol with liquid paraffin. F. GOLDBY. *Pharm. J.* 94, 316-7(1915).—Salol being quite sol. in liquid paraffin, G. recommends the following untried formula as an intestinal antiseptic: Salol, 800 grains; oil of cinnamon, 40 minims; CHCl_3 , 4 fluid drachms; Biebrich scarlet, $\frac{1}{8}$ grain; liquid paraffin to make 80 fluid ounces.

S. WALDBOTT.

A criticism of the British pharmacopeia 1914. MALCOLM M. IRVINE. Glasgow. *Pharm. J.* 94, 318-20(1915).—The criticism extends to metric wts. and measures, metric prescribing, descriptions and formulas, omissions, inferior drug standard (of aloes, benzoin, asafetida) by the side of highly developed methods of standardizing and to abbreviations.

S. WALDBOTT.

Discoloration of Na salicylate solution. W. MACADIE. *Pharm. J.* 94, 355(1915).—The black ppt. is very likely due to traces of NH_3 in air. It forms, *e. g.*, when Na salicylate is mixed with Spir. ammon. aromat. Discoloration of Na salicylate soln. is avoided completely when a basin with AcOH and cotton wool is floated on its surface.

S. WALDBOTT.

The analytical chemistry of the British pharmacopeia 1914. P. A. W. SELF. *Pharm. J.* 94, 384-5, 419-21(1915).—Quant. detns. (alkaloidal assays, non-alkaloidal detns.), limit tests, and identification and other qual. tests are discussed in detail. In *alkaloidal assays*, the use of same strength alkali with which to titrate back is condemned, owing to very low margins of difference. The acid should be 0.05 N, the alkali 0.02 N. A serious error occurs in *assay of ipecac root* where an insufficient amt. (10 cc.) of HCl is directed to remove the alkaloids from the ammoniated $\text{Et}_3\text{O}\cdot\text{CHCl}_3$ soln., whereas about 20 cc. are required. The *assay of opium* is discussed. Upon titrating back the excess of acid with alkali, mineral matters are pptd. with the morphine. Under *Na arsenite*, S. recommends substituting the starch indicator by the disappearance of the yellow color of the I soln. Under *Mel depuratum*, the statement that the soln. of the ash in H_2O is not alk. to litmus, should be corrected. A test similar to that with $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 for *strychnine*, is shown by *yohimbine*. To distinguish between both, treat the alkaloids with H_2SO_4 and NH_4 vanadate. With strychnine, an intense blue color forms, fading rapidly. On now dilg. with H_2O , a beautiful rose-pink soln. is developed. With yohimbine, a similar blue is formed, but no rose-pink color develops upon diln.

S. WALDBOTT.

The galenicals, etc., of the British pharmacopeia, 1914. J. H. FRANKLIN. *Pharm. J.* 94, 385-7(1915).—A criticism on about 35 topics. "Ether" and "ether purificatus," the latter the anesthetic, may both be prepared from industrial spirit. F. finds the purified of excellent quality (cf. following abstr.). Ext. ergotae liquid should be prepared with 40% EtOH (*C. A.* 4, 3273; 7, 3815), not with H_2O as officially required. With *syrup. ferri iodidi*, the FeI_2 soln. should be filtered into the mixt. of glucose and syrup. The addition of H_3PO_2 as a preservative (1:1000) should be allowed. *Tinct. nux vom.* has but $\frac{1}{2}$ the strength of the old tinct., yet the dose remains the same. The increase of strength of *tinct. strophanthin* by 300% is inexplicable. Standards should have been introduced for the widely used cod liver oil emulsion, compd. sirup of hypophosphites, Parrish's chem. Food, etc., which in practice vary considerably.

S. WALDBOTT.

The examination of commercial ethers. B. S. ELLIS AND ARTHUR FLETT. *Pharm. J.* 94, 387(1915).—No practical importance can be attached to detn. of sp. gr. of com. ethers, unless as a supplement to fractionation tests, in a suitable app. The data from 6 samples of com. ethers show the necessity of fractionation to obtain a uniform boiling range of 34–36°, the new Brit. Pharm. standard. They also show that ethers made from industrial alc. are the only ones yielding a large % of fractions lower than 34°, which will tend to raise the price of such ethers. Reasonable limits for sp. gr. are 0.720–0.723 at 15.5°. All com. ethers examd. showed traces of tests for aldehydes, H_2O_2 , and Me_2O , even one prepared from duty-paid EtOH. S. WALDBOTT.

Practical notes on the British pharmacopeia 1914. DAVID GILMOUR. *Pharm. J.* 94, 484–5, 500–1(1915).—The practical aspect of changes in "laudanum," the strength of acids, spirit. aether. nitrosi, glycerin, acidi boric, etc., is discussed.

S. WALDBOTT.

Pasta iodi et amyli, B. P. C. PETER BOA. *Pharm. J.* 94, 485–6, 501(1915).—In Martindale's original formula, and in Brit. Pharm. Cod. 1907, starch 1, glycerol 2 and H_2O 6 parts were *boiled* together; when cold, 1 soln. was added. The result was a firm, blue paste. In Brit. Pharm. Cod. 1911, only water-bath heat is used; an unsatisfactory semi-liquid mass of dead black color results. S. WALDBOTT.

A new color reaction for salicylic acid. P. A. W. SELF. *Pharm. J.* 94, 521(1915).—The usual color tests are not distinctive. S. finds that a combination of Kobert and Mandelin's test gives strong and characteristic colors with very small amts. of salicylic acid. Mix equal vols. of 40% $HCHO$ and concd. H_2SO_4 and cool. Moisten the substance to be tested on porcelain with the mixt., add a little NH_4 vanadate, stir well. In presence of salicylic acid, a Prussian blue color forms at once, changing rapidly to greenish blue, finally green. If the acid is absent, a yellowish red or orange color appears; this in 2–3 min. turns greenish yellow, finally green. Salicylic aldehyde is the only substance giving the same test, except that before adding the vanadate, it shows pale yellow while salicylic acid gives no color. Phenol shows pale pink before adding the vanadate, and brownish, strong pink, then brownish red and chocolate-brown, after addition. The effects of the test on 28 phenols, etc., are tabulated.

S. WALDBOTT.

A possible source of error in some alkaloidal assays. P. A. W. SELF. *Pharm. J.* 94, 585–6(1915).—Free alkaloids will expel NH_3 when evapd. with NH_4 salt solns. This happens when small amts. of the aqueous liquid, from which the alkaloid (set free by NH_4OH) was shaken out with an immiscible solvent, are evapd. together with the solvent. Titration will then give lower, gravimetric detns. higher results. Atropine showed largest loss, up to 50%, strychnine nearly 6%. From assays of belladonna leaves by Brit. Pharm. method with varying degrees of precaution it is evident that in any alkaloidal assay in which the alkaloidal residue is titrated, the accidental admixt. with even as little as 1 mg. of an NH_4 salt must be avoided, owing to the high mol. wts. of the alkaloids. It is imperative to wash the alkaloidal soln. in the volatile solvent prior to evapn.

S. WALDBOTT.

Preparation of animal charcoal for medical use. RUDOLF DITMAR. *Die Umschau*. No. 48, 1914; *allg. Oest. Apoth. Ver.* Dec., 1914; *Pharm. J.* 94, 209(1915).—Sea fish and fresh-water fish are cut into small pieces, washed and boiled with 2–5 times their vol. of H_2O for 3–5 hrs. The H_2O is then drawn off and evapd. to a sirup which is dried *in vacuo*. The residue is ground and charred in the usual way. If necessary, the charcoal is washed with HCl and H_2O . The ground product is a dark, non-hygroscopic powder with 90–95% of C, very suitable for its microbe-absorbing qualities.

S. WALDBOTT.

Analysis of a piece of resin discovered in a Moroccan vase at Port-Etienne, Cape Blanco. LOUIS REUTTER. Geneva. *Schweiz. Apoth. Ztg.* 53, 96-7(1915).—The resin consisted of greenish gray, hard pieces, softening by the warmth of the hand, of aromatic odor and enclosing débris of some dicotyledonous plant. The greater part was sol. in Et₂O, a large amt. in oil of turpentine, EtOH, nearly all sol. in CHCl₃, CS₂ and KOH. M. p. 70-72°. Acid no. 126-131.5; sapon. no. 225-234. With KOH, a strong odor of turpentine is evolved. Further tests showed the presence of sugar and mucilage, but the absence of cinnamic acid, storax, myrrh, ammoniacum, mastic, incense, bdellium. The aromatic part of the resin was evidently the exudate of *Pistacia terebinthus*, family of Anacardiaceae. S. WALDBOTT.

Analysis of a Roman pomade. L. REUTTER. *Schweiz. Apoth. Ztg.* 53, 130-2 (1915).—A specimen from a Roman amphora in the Locarno Museum was brownish yellow, soft, sticky, m. 58°, and had the odor of turpentine and storax. Analysis showed that this pomade was no doubt prepared by macerating resin of turpentine and storax in wine, to which an oily ext. of Henna and perhaps other aromatic plants were added as perfume, then beeswax and animal greases. S. WALDBOTT.

Optochin hydrochloricum. J. MORGENROTH. Fleissig. *Schweiz. Apoth. Ztg.* 53, 139-40(1915).—Another name for ethylhydrocuprein. Cf. C. A. 8, 182. S. W.

The calcium and the lithium salts of *o*-acetoxybenzoic acid. "J. A." *Schweiz. Apoth. Ztg.* 53, 177-9(1915).—The 2 salts decompose easily in presence of moisture; hence they are prepared by the aid of organic solvents. FeCl₃ gives a yellow brown ppt. with the pure salts; a violet color indicates decompn. The H₂O soln. of the pure Ca salt is neutral or faintly acid. Upon decompn. it becomes strongly acid; the acidity may be measured by titration. The com. names of the Ca-salt are "aspirin-soluble" and "kalmopyrin;" of the Li salt, "hydropyrongrifa" and "apyron." S. W.

The active principle of sulfur baths. O. v. SPINDLER. Zürich. *Schweiz. Apoth. Ztg.* 53, 217-20(1915).—The tonic activity of sulfur baths is not due to the small amts. of sulfides as such, or to free H₂S contained in the waters, but to colloidal S formed by oxidation of H₂S or sulfide solns. in contact with air and CO₂. It is suggested that some active organic S compd., e. g., ichthyol, which, however, is too expensive, might ultimately replace the use of natural S springs. S. WALDBOTT.

Seeds of Trichilia (AMMANN) 27. Detection of cinnamic acid (SCHENK) 7. Glass for ampoules, etc. (KROEBER) 19. Test for sesame oil in olive oil (SAGE) 27. Organic chemical industry in Gt. Britain (PERKIN) 10.

U. S., 1,138,936, May 11. A. B. DAVIS. 2-(*p*-Hydroxy-*m*-methoxyphenyl)-6-methylquinoline-4-carboxylic acid of the formula

is made by boiling a soln. of pyruvic acid 44, *p*-toluidine 54 and vanillin 76 parts, in abs. alc. The product seps. from alc. as deep orange colored crystals. Similar compds. derived from 2-[*p*-hydroxy-*m*-methoxyphenyl]-quinoline-4-carboxylic acid by boiling together in abs. alc. soln. equimol. proportions of an aromatic amine, pyruvic acid and

vanillin. Thus from the toluidines and anisidines are formed the corresponding substituted quinoline compds.; *m*- and *p*-anisidine, and *o*- and *m*-toluidine yield, resp.: 2-[*p*-hydroxy-*m*-methoxyphenyl]-8-methoxyquinoline-4-carboxylic acid, 2-[*p*-hydroxy-*m*-methoxyphenyl]-7-methoxyquinoline-4-carboxylic acid, 2-[*p*-hydroxy-*m*-methoxyphenyl]-6-methoxyquinoline-4-carboxylic acid, 2-[*p*-hydroxy-*m*-methoxyphenyl]-8-methylquinoline-4-carboxylic acid and 2-[*p*-hydroxy-*m*-methoxyphenyl]-7-methylquinoline-4-carboxylic acid. If ethyl *p*-aminobenzoate be the amine used, then the product is 6-ethyl 2-[*p*-hydroxy-*m*-methoxyphenyl]quinoline-4,6-dicarboxylate. These compds. are useful as mobilizers for uric acid.

U. S., 1,138,937, May 11. A. B. DAVIS. 6-Ethyl-2-phenylquinoline-4,6-dicarboxylate is made by boiling together in abs. alc. equimol. proportions of Et *p*-aminobenzoate, BzH and pyruvic acid. It is a white cryst. powder. Compds. similarly prep'd. are: 6-ethyl 2-[*m,p*-methylenedioxyphenyl]quinoline-4,6-dicarboxylate (from heliotropine, Et *p*-aminobenzoate, and pyruvic acid); 6-ethyl 2-[*o*-hydroxyphenyl]quinoline-4,6-dicarboxylate (from salicylic aldehyde, ethyl *p*-aminobenzoate and pyruvic acid); 6-ethyl 2-[*p*-methoxyphenyl]quinoline-4,6-dicarboxylate (from *p*-anisaldehyde, ethyl *p*-aminobenzoate and pyruvic acid); 6-ethyl 2-[*p*-hydroxy-*m*-methoxyphenyl]quinoline-4,6-dicarboxylate (from vanillin, ethyl *p*-aminobenzoate, and pyruvic acid). All of these are yellow to white cryst. powders, slightly sol. in alc., insol. in water and *m*. at high temps. They are sol. with decompn. in strong H₂SO₄ and in hot conc'd. alkalis. All are for pharmaceutical use.

Brit., 29,546, Dec. 22, 1913. BOEHRINGER & SOEHN. Mono- and dinitro-aminophenylarsonic acids and their derivs. are prep'd. by treating 4-Cl-mono- or dinitrophenylarsonic acids with NH₃ or its derivs., the product being further nitrated if a dinitro comp'd. is desired and a mononitro comp'd. is the parent substance. NH₃ derivs. include primary and secondary amines, and compds. of the type of aminoacetic acid, phenylsulfonamide, and piperidine. 3,5-Dinitro-4-chlorophenylarsonic acid for use as a parent material is obtained by direct introduction of 2 NO₂ groups into 4-Cl-phenylarsonic acid, or by further nitration of the mononitro comp'd. 4-Chloro-3-nitrophenylarsonic acid is prepared by nitration of 4-Cl-phenylarsonic acid.

Brit., 28,736, Dec. 12, 1913. G. B. ELLIS. *p*-Dimethylaminophenol and *p*-hydroxyphenyltrimethylammonium hydroxide are sep'd. from solns. containing both products by adding a ferrocyanide and acidifying with a mineral acid. The mixed acid ferrocyanides resulting are sep'd. either by extn. of the weakly alk. soln. of the mixed salts with C₆H₆, Et₂O, etc., whereby the *p*-Me₂NC₆H₄OH is removed, and then seg'd. the pure ferrocyanides from the ext. and residue, resp., or by recrystg. the mixed acid salts with alkali sulfite whereby the neutral ferrocyanide of *p*-Me₂NC₆H₄OH is obtained cryst. The pure bases and other salts may be prep'd. from the ferrocyanides.

Brit., 29,841, Dec. 24, 1913. F. HEINEMANN. Iron salts of therapeutic value are prep'd. from the arseno- and phospho- derivs. of fatty acids described in 18,732, 1912 (C. A. 7, 2096). The examples describe the production of Fe salts from the chloroarsenobehenolic acid obtained according to example B described in the principal patent, by neutralizing the MeOH soln. of the acid with alc. NaOH and adding alc. FeCl₃; by adding an alc. soln. of the acid to liquor ferri oxychlorati of the German Pharmacopoeia and by mixing a soln. of basic Fe acetate with alc. and an alc. soln. of the acid.

Brit., 30,047, Dec. 31, 1913. K. H. SCHMITZ. Methylhexamethylenetetramine thiocyanate. See Fr., 466,619 (C. A. 9, 1369).

Brit., 30,068, Dec. 31, 1913. FABRIQUES DE PRODUITS DE CHIMIE ORGANIQUE DE LAIRE. Chlorohydrocarbons containing the group CH₂Cl are prep'd. by condensing an aromatic hydrocarbon with chlorodimethyl ether or a homolog in the presence of

SnCl_4 , SbCl_5 , AlCl_3 , Fe_2Cl_6 , ZnCl_2 , TiCl_4 , etc. In an example the treatment of toluene is described, *p*-methylbenzyl chloride and a dichloro compd. resulting. Similarly, there may be prepd. chloromethylethylbenzene, -propylbenzene, -butylbenzene, -amylbenzene, -cyclohexylbenzene, -ethyltoluene, -propyltoluene, -butyltoluene, etc. Alcohols, aldehydes, acids, and ethers may be prepd. from the chlorohydrocarbons obtained as above described.

Brit., 30,072, Dec. 31, 1913. BAYER & Co. β -Naphthisatin and its derivs. See Ger., 269,750 (C. A. 8, 2221).

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Reburning of lime from alkali waste and other forms of precipitated carbonate of lime. R. K. MEADE. *Met. Chem. Eng.* 13, 289-90(1915).—Where lime is being purchased at a cost of \$3 per ton it will generally prove economical to put in a lime recovery plant, provided the quant. sludge obtained is not too small. If properly installed a kiln 6 ft. in diam. and 100 ft. long will burn at least 30 tons of quicklime per day when working on a waste containing 45% H_2O . The cost, including interest on the investment and depreciation, will vary between \$2 and \$3 per ton, depending on the quantity of waste to be recovered and cost of fuel. The power required by the plant will amount to about 15 kw. hrs. per day. M. has designed a plant (diagram given) in which the % of H_2O in the waste is reduced as low as will permit of the pumping of the latter. This is done by allowing the waste to settle in 2 tanks provided with a movable syphon tube. The contents of one tank are allowed to settle while those of the other are fed to the kiln. The sludge is allowed to settle for 24 hrs., when the H_2O is drained off. The slurry is then agitated with compressed air to make it of uniform consistency, and pumped into the kiln with a small centrifugal pump. A valve controls the flow of slurry and the excess goes back into the tank and serves to keep the contents agitated. The rotary kiln is of the ordinary type. A small plant (including gas producer), which will have a capacity of about 10 tons lime per day, may be put up for about \$12,000-\$15,000. If oil or natural gas is to be used for fuel the cost will be materially less. The recovered lime, if burned at all skilfully, will contain fully as much caustic lime as the best lump lime made from limestone.

C. A. NOWAK.

Theoretical and practical study of the manufacture of sodium hypochlorite from sodium hydroxide. U. CATTANIA AND C. RANUCCI. Palazzolo. *Ann. chim. applicata* 3, 161-4(1915).—In a sandstone vessel, Cl was allowed to pass through a 28° Biné NaOH soln., which was kept agitated, while the vessel was cooled by an external water bath. In 10 min., 1 hr., 2 hrs., 3 hrs., and 3½ hrs., resp., the soln. showed 2.30, 6.82, 10.43, 13.65 and 17.70% active Cl, with NaOH in excess amounting to 17.94, 12.75, 7.89, 5.14 and 1.50%. These test samples analyzed a day later showed, resp., 2.30, 6.75, 9.10, 6.20 and 2.80% active Cl. A small amt. of free NaOH, not exceeding 0.5%, should be allowed to remain in order to prevent decompn. of the hypochlorite by the CO_2 of the air, and by HClO and HCl always present in the liquid. It was found that by removing the NaCl gradually as it was deposited from the liquid, the hypochlorite formed retained its activity in full after standing 24 hrs. S. LEVY.

The development of the chemical industries in Canada. H. G. *Chem. Ind.* 38, 94-5(1915). F. W. SMITHER.

The chemical industry of Sweden and the war. ALF. LARSON. *Chem. Ztg.* 39, 253-4(1915). E. H.

The chemical industries of Germany. PERCY FRANKLAND. *Pharm. J.* 94, 353-4 (1915); *J. Soc. Chem. Ind.* 34, 307-16(1915); *Mét. Chem. Eng.* 13, 378-87(1915).—A descriptive account and discussion of the causes of German success in chem. industries. S. WALDBOTT.

Ammonium magnesium sulfate (PORLEZZA) 2.

U. S., 1,137,043, Apr. 27. F. P. WOOD. Fusible adhesive for use in making paper-walled receptacles; composed of gilsonite 30, linseed oil 4 and vaseline 15 parts. Parolite or elaterite may be substituted for gilsonite and China wood oil for linseed oil.

U. S., 1,137,181, Apr. 27. O. BERG. Granulating calcium nitrate, etc., by drying and hardening in a rotating drum and scraping off in the form of flakes which are allowed to collect at the point of removal until the compression causes them to become granulated. They are then subjected to a current of air to cool them and prevent them from sticking together.

U. S., 1,137,366, Apr. 27. W. R. UHLEMANN. Fusible cement for eye-glass mountings, formed of shellac 15, bronze leaf powder 8 and powdered talc 10 parts.

U. S., 1,137,373, Apr. 27. J. W. AYLSWORTH. A composition for making bearings, valve disks, brushes for electric motors, etc., is formed by treating flake graphite with hot conc. HNO_3 for 0.5-2 hrs. and then heating to about 500° after washing, to expand the graphite to several times its original bulk and open up and separate the laminae of which it is composed like the leaves of a book, and finally mixing the expanded material with a phenolic condensation product, with or without wood flour or other filler.

U. S., 1,137,617, Apr. 27. P. R. HERSHMAN. Obtaining alkali-soluble alumina from alunite by calcining it and then heating with 20-50% of C in an atm. of N or CO to about $1450-1650^\circ$ for 0.5-2 hrs. Heating in air or CO_2 gives a less completely sol. product.

U. S., 1,137,774, May 4. E. MAZZA. Separating constituents of air or other gaseous mixtures, by centrifugal action.

U. S., 1,137,806, May 4. R. STEWART. Producing calcium hydrogen phosphate by treating phosphate rock with steam and the smoke from a smelter, containing SO_2 and SO_3 , to form CaHPO_4 and $\text{Ca}(\text{HSO}_4)_2$, oxidizing the soln. obtained by the action of an elec. current and evapg. to recover the CaHPO_4 .

U. S., 1,137,860, May 4. H. HOWARD. Removing silica from aluminate solutions by treating the hot soln. at a concn. of about 23-25° Bé. with the residues remaining after the digestion of bauxite with alkaline aluminate soln.

U. S., 1,137,871, May 4. S. H. LAWTON. Purifying zinc chloride solutions containing dissolved ferric salts, such as obtained by treating galvanized iron scrap with hydrochloric acid. ZnO , ZnCO_3 or basic Zn chloride is added to the soln. and it is then conc. by evapn. to about 85-95° Bé. to convert the Fe into anhyd. Fe_2O_3 .

U. S., 1,138,190, May 4. J. E. BUCHER. Fixing atmospheric nitrogen by bringing free N and Na vapor into contact with a catalyst formed of Fe, C and Na_2CO_3 at a temp. of about $920-1000^\circ$ to form NaCN and supplying fresh C to the catalyst as it is consumed by the reaction. Na metal may be used to start the reaction or, instead, NaOH, NaOAc, NaHCO_3 or Na oxalate may be used with an easily reducible Fe compd. and C. Cf. C. A. 9, 357.

U. S., 1,138,191, May 4. J. E. BUCHER. Fixing free nitrogen by bringing it into contact with Na_2CO_3 and a catalyst formed of a finely powdered mixt. of Fe and

graphite at a temp. of about 725° , to form NaCN. The latter may be acted on with steam, as formed, if desired, to produce NH_3 .

U. S., 1,138,595, May 4. W. H. STANTON and J. G. VAIL. **Dissolving alkali silicates** without agitation by covering an excess of the silicate with H_2O and then surrounding the receptacle in which it is contained with steam to form a soln. sufficiently conc. that the rate of solution is not reduced by hydrolysis.

U. S., 1,138,658, May 11. H. HOWARD. **Drying sodium hydrogen sulfite crystals** by a current of hot SO_2 . The latter is repeatedly used after removal of moisture from it by cooling and condensation. $\text{Na}_2\text{S}_2\text{O}_3$ may be similarly dried without decomn. Cf. C. A. 8, 2783, 3222.

U. S., 1,138,676, May 11. W. J. LONGMORE. **Making electrical insulation in sheet form** by collecting a shower of mixed mica scales and shellac or other binder upon a heated plate and subjecting the layer thus formed to pressure beneath another heated plate.

U. S., 1,138,691, May 11. J. H. SANBORN. **Electrical insulation in sheet form** is made by allowing mica flakes and powdered shellac to settle through a tall chamber filled with air and heating and pressing the layer of the mixt. which collects on the floor of the chamber.

U. S., 1,138,751, May 11. W. M. GROSVENOR. **Apparatus and method for drying glue in a current of dry, purified air.**

U. S., 1,139,291, May 11. C. F. JENKINS. **Coating lace or other textile fabrics, wood, paper, etc., with metals.** A wire of the coating metal is fused by passing an elec. current through it and the fused metal is atomized and projected upon the article to be coated by the explosive action of O and H or other explosive gases introduced into the tube in which the elec. fusion takes place. The highly heated particles of metal serve to ignite the gases.

Brit., 29,254, Dec. 18, 1913. G. HUNNYBUN. The heat generated by the combustion of S is utilized for the recovery of sulfuric acid from bisulfates. In an example, pulverized S is mixed with powdered or liquid NaHSO_4 , and the mixt. roasted in an open pan until the S ignites. The free acid is driven off along with SO_2 , the residue consisting chiefly of Na_2SO_4 .

Brit., 29,521, Dec. 22, 1913. G. MASON. **Impregnating compositions for sacks,** such as cement sacks, etc., to render them dust-proof, comprises gelatin, black molasses, alum or chrome alum, and petroleum product. The gelatin is heated with H_2O , the molasses is added, and subsequently chrome alum. The heating is then stopped and the petroleum product added.

Brit., 29,621, Dec. 23, 1913. S. A. C. KRISTENSEN. **Light-weight printing-blocks** are made by pressing into a suitable matrix (1) a compd. consisting of a metal powder, such as Al, and an adhesive such as water glass, or (2) an unsized paper coated with the comp., the block being completed in each case by the application of a filling or backing medium, such as plaster of Paris alone or mixed with celluloid. An oiled celluloid, metal, or paper matrix is employed, or a rubber or wax matrix may be used. When the metal compn. alone is employed, it is pressed into the matrix by a soft brush and when this is dry, thin linen or tissue paper coated with the metal compn. is applied and also pressed; when this is dry, the filling medium is applied. The completed block may be detached from a rubber or wax matrix by melting this. The completed block is mounted on wood. For auto-types, no filling medium is required, and the printing surface, when pressed into its matrix, is coated with an adhesive so that it can be applied directly to a plane or curved support. Cf. C. A. 8, 1490.

Brit., 29,827, Dec. 27, 1913. M. SPAZIER. Sodium carbonate crystals. See U.S. 1,122,323 (C. A. 9, 516).

Brit., 29,934, Dec. 30, 1913. J. WOLFENDEN. A composition for removing gloss from worn garments consists of vinegar, turpentine, oil of tar, benzine, and spirits of camphor. The mixt. is boiled, and the vapor passed through the clothes from the inside.

Brit., 30,035, Dec. 31, 1913. J. S. ELDER. A plastic composition for application to surfaces subjected to friction, such as boot soles and heels, consists of about 20% of gutta-percha, 5% of rubber, 5% of shellac, and 70% of metal in granular form, such as Fe filings. The ingredients are heated and kneaded until homogeneous. For repairing boots, the surfaces to be patched are coated with coal tar and Archangel tar, and the comp. while warm is applied like putty.

Brit., 41, Jan. 1, 1914. E. STAUBER and W. KOCHAN. Ammonia. See Fr., 464,227 (C. A. 9, 1376).

Brit., 234, Jan. 5, 1914. J. H. HARGREAVES and G. K. DAVIS. Iodine and other products, such as sodium or potassium salts, combustible gases, oils, tar, ammonia, etc., are obtained by burning seaweed by admission of air in a series of vertical chambers, the gases from the chamber in which combustion is taking place being passed downwards through the seaweed in the remaining chambers of the series, each chamber becoming in turn the last, intermediate, and first in series.

Brit., 337, Jan. 6, 1914. R. FABRY. An app. for dissociating chemical solutions, e.g., decomposing crude ammoniacal liquor into caustic ammoniacal liquor and gaseous H_2S and CO_2 , transforming bicarbonate solns. into normal carbonate and CO_2 , or treating combined solns. of alkali bicarbonates and NH_4 compds. resulting from the washing of coal-gas with a soln. containing NH_3 and alkali carbonate, consists of a still, a dephlegmator to which the vapors from the still are led by a pipe, and a preheater to which the residual liquid from the still is led by a pipe, the plant being so arranged that the crude liquor is fed in proportions regulated by valves partly through a pipe to the dephlegmator, and partly by a pipe to the preheater. The liquor fed to the dephlegmator seps. H_2O and NH_3 from the escaping gases, and flows, together with liquor from the preheater, through the vapor pipe (from the still to the dephlegmator) to the still. The still is fitted with a steam heater. The app. may be worked under pressure to avoid loss of NH_3 .

Ger., 279,699, Oct. 8, 1913. M. DIEBOLD. Preparing permanent macroscopic exhibits by imbedding the object in a nitrocellulose soln. which is afterwards hardened. The hardened block is satd. with a transparent colorless material, fast to light, having no solvent action on cellulose, and with a refractive index of 1.35-1.65. The block is rendered as clear as glass by this means.

Ger., 280,032, July 20, 1913. R. PIETERS VAN CALCAR, J. ELLERMANN and H. J. MARTIJN. In drying air, the $CaCl_2$ soln. which drops down from the solid salt used is caught in a deep tray containing porous material (wadding, sponge, or felt, mounted on rods or spirals) which absorbs the soln. and serves to abstract moisture from the moist air as it enters the app.

Ger., 280,499, Jan. 31, 1913. BADISCHE. Mfg. nitrogen oxides. See Brit., 9,263, 1913 (C. A. 8, 3355).

Ger., 280,821, Jan. 3, 1913. Addition to 273,132 (C. A. 8, 2608). E. WEIDINGER and DRESER. Insulating plates are prepd. from feldspar and mica, or from either of these alone instead of from the 3 constituents of granite as specified in the principal patent. Also, instead of a soln. of caoutchouc in turpentine, a soln. of other high

melting colloids may be employed, such, *e. g.*, as an asphalt soln. In this case the addition of H_2O is unnecessary.

Ger., 280,863, July 1, 1913. R. JORDAN. Coating acid-proof containers, to be used for transporting acids. The glass, earthenware, or like vessel is provided with 3 coats which blend together at the fusion temp. The 1st coating is made of bituminous and fibrous materials, such as jute or hair, and the 2nd coat consists of a flexible layer of wood, peat, and the like, while the outer coating is strengthened by sand or gravel. A blow applied from without is transmitted to the middle layer in which the shock is absorbed with consequent protection of the glass vessel.

Ger., 281,004, Feb. 5, 1914. Addition to 261,922 (C. A. 7, 3645). F. MEYER. The principal process for effecting chemical reactions at a high temperature is modified in that the flame is directed against, instead of through or into, the reaction mass. Molten, instead of pulverulent products, are obtained, and re-oxidation is prevented by a film of oxide. The process is applicable in all cases wherein 1 of the components concerned in the reaction is non-volatile, *e. g.*, in the reduction of oxides to metals, or in the production of nitrides from oxides. The process is applicable also to the smelting of the precious and base metals. As the flame is directed against the metal itself, the crucible remains relatively cold. The charge itself may serve as the crucible, thereby ensuring greater purity of the product. The temp. and reducing power of the flame can be increased greatly by increase of pressure, even the temp. of the elec. arc being attained.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Glasses for protecting the eyes from infra-red rays. W. W. COBLENTZ. *J. Frank. Inst.* 179, 579-80(1915); see fig.—Curve No. 1 gives the transmission through a sample of glass, 1.47 mm. in thickness, yellowish brown color, maker's No. "G124, H.L., shade No. 1." Curve No. 2 gives results from a much more opaque sample of

the same kind of material, 2.16 mm. thick, marked "G5, C. A. D., shade No. 4." It transmits about 5% in the "orange" part of the spectrum, while No. 1 transmits almost 30% in the "orange." These samples absorb also the violet end of the spectrum. The transmission curve No. 3 is of a sample with a faintly bluish tint, being quite colorless; the infra-red is marked by almost complete opacity. Thickness = 2.6 mm; makers' No. "G124 J." This will make excellent spectacle glass for working near a "red-hot" source which emits but little light, but which emits a great deal of "heat," i. e., infra-red radiations. It was shown in a previous article (*Carnegie Inst. Pub. No. 97*) that ordinary black glass ("smoked glass") is quite transparent in the infra-red, although it is quite useful for reducing the visible radiations. No. 3 is the first sample found to fulfil the claim of great opacity in the infra-red. Another blue glass (Corning G 401ZA and Schott's blue-violet glass No. F 3086) has practically the same form of transmission as curve No. 3 in the infra-red; this is shown in curve No. 4. The peculiarity of this glass is that a high transmission in the visible gives a high transmission at 2.2μ . Samples made by the Corning Glass Works.

F. W. SMITHER.

Examination of glass for ampoules and medicine bottles. L. KROEBER. *Apoth. Ztg.* 29, 974-8(1914); *Schweiz. Apoth. Ztg.* 53, 147-51.—Fiolax Jena glass (cf. C. A. 6, 3432) answers the strict requirements for ampoules and especially stands the test of Mylius (C. A. 8, 1000). The scale of sensitiveness towards free alkali in decreasing order is narcotine-HCl, strychnine-HNO₃, phenolphthalein, HgCl₂, morphine-HCl. The German Ministry of War requires this test: Fill the rinsed ampoules with weak phenolph. soln., heat the tubes, close them by fusion, heat again to 100° for 1½ hr. The contents must not show red color. Anneler's test (C. A. 7, 2451) with 0.1% narcotine-HCl soln. is by far the most sensitive. For medicinal glass in general, many possibilities of dangerous ppts. in inferior glass are cited. K. recommends filling the glasses with CO₂-free H₂O containing 2-3 drops of phenolph. in 100 cc. Heat in a current of steam for at least 1 hr. Allow to stand 24 hrs. The contents should be colorless or faint pink, and the color should disappear upon adding 2-3 drops of 0.1 N HCl. The following summary of treatment is given: Sterilize in a current of steam for 1½-1 hr. After 24 hrs., dist. H₂O should show no glittering silicates. Morphine-HCl soln. 1-2% should show at most a faint yellow color. Strychnine-HNO₃ 0.6% should not deposit cryst. needles. HgCl₂ should not ppt. colored oxides. Phenolph., see above. Narcotine-HCl soln. 0.1% at room temp. should not ppt. or only very slightly, after 1 hr. Sterilize for 1 hr. with a 1% HCl soln., then wash until litmus no longer shows acid.

S. WALDBOTT.

Jena glass. C. BÜHRER. *Schweiz. Apoth. Ztg.* 53, 169-73(1915).—An account of the historical and technical development of Jena glass and "Fiolax." Cf. preceding abstr.

S. WALDBOTT.

The chemical properties of glass. C. BÜHRER. *Schweiz. Apoth. Ztg.* 53, 186-9 (1915).—A review of articles by Moeller, Baroni, Anneler and L. Kroeber. Cf. preceding abstr.

S. WALDBOTT.

Refractory materials; their definition and their tests. *Ceramique* 17, 202-4. (1914).—In estg. the refractory degree of a substance the following points should be considered: (1) The temp. to which the substance can be heated without melting; (2) the uses to which it will be put and whether it will withstand variations in temp. and maintain a volume sufficiently nearly const. to have no detrimental effect; (3) its resistance to the action of basic or other agents such as lime, cement, magnesia, clinker and corrosive gases. Methods are given for testing these points. J. C. EVANS.

The specific heat of refractory products. W. STEGER. *Silicat-Z.* 2, 203-5(1914). Within one and the same temp. range the sp. heat of all ceramic mixts. is practically

the same. The value increases as a straight line function with temp., averaging about 0.204 between 20 and 200° and about 0.225 between 20 and 400°. The value is not affected at all by method of manuf. or the burning temp. and but slightly by a change in chem. comp.

C. S. KINNISON.

The coefficient of expansion of glazes. R. RIEKE AND W. STEGER. *Sprechsaal* 47, 577-8, 585-6, 593-5, 601-4(1914); cf. C. A. 8, 3846.—The base glaze used in the study was 0.3 CaO, 0.7 PbO, 0.2 Al_2O_3 , 2.1 SiO_2 , 0.4 B_2O_3 . This RO was kept constant while the Al_2O_3 varied from 0.0 to 0.40, to SiO_2 from 2.0 to 3.0 and the B_2O_3 from 0.0 to 3.0. The coeff. of expansion was measured between room temps. and 100°. *Conclusions:* An increase of the SiO_2 or a replacement of B_2O_3 by SiO_2 in equimol. proportions lowers the coeff. of expansion. (2) The addition of Al_2O_3 up to 0.30 equiv. always lowers the coeff. of expansion. In SiO_2 -free, boric acid glasses, raising the Al_2O_3 content above 0.20 equiv. raises this coeff. (3) Increasing the B_2O_3 or replacing the SiO_2 by B_2O_3 in equimol. amts. raises the coeff. Only in SiO_2 -free glasses or those very high in B_2O_3 does an addition of the latter raise the coeff. (4) There is no direct relation between the magnitude of the coeff. of expansion and its behavior as regards crazing and shivering.

C. S. KINNISON.

Process of the metallization of porcelain. M. P. MARINO. *Ceramique* 17, 188 (1914).—The object is first covered with a coat of AgF and then exposed to a stream of illuminating gas. The SiO_2 of the porcelain combines with the F and Ag is liberated. The liberated Ag penetrates the pores of the article and adheres to the surface, provided the surface is rough and not glazed. The object is then exposed to vapors of CS_2 at about 50°. The CS_2 reacts with Ag to form Ag_2S ; CF_4 is also formed, and both of these form a strong, adherent coat. To increase the adherence the surface can be brushed with a revolving brush of brass, zinc, copper or other metal. The object is finally made the cathode in a soln. of a metal salt and metallized by electrolysis. Pottery can also be coated with Ag_2S by treating the surface with a soln. of $AgNO_3$ and subsequently dipping it in a solution of H_2S .

J. C. EVANS.

Preserving the resisting quality of ceramic bricks. LA SOCIÉTÉ UTZSCHNEIDER ET JAUNEZ. *Ceramique* 17, 178(1914).—Bricks or flagstone which are resistant to acids and frost are made by adding to the ceramic paste before mixing carborundum grains dipped in a frit. The grains added, although completely enveloped by the fritted material, are not attacked during the burning and the resultant material has a rugged appearance and a minimum contraction; its resistance to acids is not impaired.

J. C. EVANS.

Preparation of humid clay for dry pressing. ANON. *Ceramique* 17, 187-8(1914).—The addition of the correct amt. of milk of lime in place of $CaCO_3$ to argillaceous pastes followed by the addition of fine sand offers the following advantages: (1) It gradually raises the humidity of the clay; (2) it secures a better consolidation of the product; (3) it brings about desiccation, without cost, of the mixt., which can subsequently be pressed dry. The amt. of lime that combines with the clay matter should be detd. and that much, only, added. The fine sand can be added either during or after mixing with lime. This fine sand with some of the clay matter combines with the lime and fills the voids during vitrification; it gives a more compact material.

J. C. EVANS.

Firing and burning. ERNST SCHMATOLLA. *Brick Clay Record* 45, 487-90, 600-2, 697-9, 791-3, 1092-4(1914).—Two types of liquid fuel burners are described, the oil being atomized either by pressure or a steam-jet. An illustration is given of a small testing kiln heated by crude oil, atomized by steam, and the burning is described. The front view, side elevation and plan of a clamp-kiln are shown and the building of the firing arches, the flues, and the setting of the kiln described. S describes a method

for utilizing the waste heat from clamp kilns for drying purposes. Two round type up-draft kilns are shown, one of which represents the kind used in potteries; it has 2 or 3 chambers arranged above each other for the best utilization of the heat. A horizontal draft, periodical kiln, a semi-continuous kiln, and a continuous ring-system of down-draft kilns are also described briefly with illustrations. A description is given of the following kilns: (1) A down-draft kiln which may also be operated with horizontal draft and which is equipped with a semi-gas producer and a heat recuperator; (2) a combination pottery kiln, consisting of two up-draft chambers arranged above one down-draft chamber; (3) a one-chamber up- and down-draft kiln cf. the Hook patent kiln, (C. A. 8, 3494). It has two sets of furnaces, one burning from the top downward and the other from the bottom upward, thus insuring an even burn throughout the kiln; (4) a center-stack, down-draft kiln with auxiliary furnace arrangement for heating the kiln bottom and stack; (5) a semi-continuous kiln system for round, down-draft kilns; (6) a steel-jacketed, down-draft kiln. Different ways of setting, water-smoking and firing down-draft kilns are described with illustrations. Seven illustrations of the Hoffmann continuous horizontal-draft kiln with a detailed description of the methods of operation for both coal and gas firing are given. Advantages of the zig-zag type of the Hoffmann kiln are mentioned. S. describes the construction and operation, with illustrations, of the continuous compartment kiln, the tunnel kiln and the regenerative kiln.

ROBERT BACK.

Some tests upon large brick piers. J. H. GRIFFITH AND J. G. BRAGG. U. S. Bureau of Standards. *Clayworker* 63, 367-373(1915).—The strength of large piers under vertical loading in common with smaller piers bears a close relation to the kind of brick used and the quality and age of mortar. The specimens laid in the cement (1:3) and the cement and lime (15% + 85% = 1:3) mortars have an equiv. strength for any one grade of brick. The relative strengths of piers of vitrified, hard and soft (A, B and C) brick laid in these mortars are approx. in the ratio of 5:3:1. The ratio of the max. unit loads of the piers laid in the above mortars compared with those laid in the 1:6 lime mortar is about 2:1 for the A, B and C grade, resp., this ratio being still larger (about 4:1) in the case of "C specification" brick laid in 1:3 mortar. The low strength of piers laid in the lime mortars is attributed in the main to insufficient aging with a consequent lack of proper carbonation of the mortars. The expts. thus far conducted seem to indicate that the strength of a pier is largely independent of the course bonding, the real function of bond being, it is believed, to maintain a certain integrity and monolithic action of the masonry against initial strains induced through setting and "drying out" of the mortar rather than any great increase of vertical strength due to the bonding. The slight increase of strength with the increase of distance between header courses is thought to be inconclusive on account of a probable reduction in the effective resistance of the bonding courses chosen due to the presence of too many fractional brick. The mean moduli of the piers of A and B specification brick laid in cement mortar was 3,000,000 lbs. and 2,500,000 lbs., resp., the corresponding figures for piers in the lime and cement mortar being somewhat lower. The "elastic limit" of the piers in the cement and cement and lime mortar is approx. one-half the max. load. Piers fail through a tendency to sep. into vertical laminae caused by transverse failure in the individual brick occurring from flexural action produced through unequal distribution of the vertical load over the cross section, together with ineffective shearing and adhesive strength of the mortar. Uniformity in the brick dimensions is also a factor to a lesser extent in reducing unequal compressions of the joint, as is the thickness of joint itself. A high modulus of rupture is more desirable than superior crushing strength, as far as these can be differentiated in their inter-relations. A higher modulus of rupture would be realized in practice either by increasing the thickness of

the bricks or by laying them on edge so as to give their greatest flexural efficiency. A further study of the action of steel mesh reinforcing is recommended in order to ascertain the load efficiency of piers having an outer shell of hard brick with an inner core of softer brick in the case of districts which are unfavorably located for the production of the higher grades of brick.

ROBERT BACK.

The efflorescences and the spots of burnt earths. ANON. *Ceramique* 17, 186-7 (1914).—To prevent efflorescence in burnt material the following means are discussed: (1) washing out the sol. salts in the earths, avoiding water containing dissolved salts; (2) preventing the concn. of the sol. salts in the earths on the surface of the product; (3) eliminating the efflorescence by chem. reactions during the burning. Washing the earth with water containing BaCl_2 to transform the sol. sulfates into BaSO_4 seems to be more successful than washing with pure water. Under (2) the following methods are discussed: (a) steeping the product before burning in a paste of burnt material and yellow clay so as to produce a red coloration all over the surface; (b) steeping the earth in a very sol. salt of iron, which diminishes the solubility of the lime salts contained in the earth and also gives a red color on the surface; (c) applying to the surface of the earth a film consisting of the product of the condensation of CH_3O and PhOH . This film absorbs the sol. salts during the first stages of the burning and they are later volatilized with the film. Finally the effect of a blast of sand to remove the spots on the burnt material is mentioned.

J. C. EVANS.

Kiln expansion and bracing. C. B. HARROP. Ohio State Univ. *Clayworker* 63, 353-9(1915); 24 figs.; *Brick Clay Record* 46, 566-569, 656-660(1915).—Since the expansive force of kiln walls is practically irresistible, expansion joints are a prime necessity. The greater the number of expansion joints in a given length of wall, the smaller they may be and the less the chance of damage to the wall. It is possible to make expansion joints too large. Thorough bonding of lining to the main wall is essential. The crowding out of kiln walls is inevitable (except in cases of very special construction), but this action can be retarded to a great degree by first-class material and careful workmanship. Probably the greatest damage is done by the expanding of the kiln floor. The floor should have expansion joints on all sides. Cracks in kiln walls, especially those near the bottom, are sources of considerable loss. The single I-beam brace for rectangular kilns is stronger and cheaper than the older form of trussed channel brace. The wedge brick starter for rectangular kiln crown arches has no advantage over the ordinary skewback starter, although in round kilns there may be some slight advantage. Theoretically the crown of a rectangular kiln produces but very little more thrust at the heel when hot than when cold. The steel bands used for supporting the crowns of round kilns are often made heavier than necessary. If the upper part of the wall of a round kiln and the lower part of the crown contain sufficient expansion joints to take care of horizontal expansion, there should be but little more thrust at the heel when hot than when cold.

ROBERT BACK.

Thermo-technical calculations for a gas chamber furnace for burning clay ware. L. LITINSKY. *Feuerungstechnik* 3, 117-120(1915).—L. describes a 14-chamber gas furnace, with several illustrations, indicates the course of the flames and hot gases, manner of combustion and the advantages derived from the use of this type of furnace. Methods of calcg. of the following are given: gas yield, efficiency of generator, max. theoretical temp., dimensions of furnace, fuel consumed, combustion products, cross-section of gas passages and the dimensions of generator and chimney.

H. R. GUNDLACH.

White-burning clays of the Southern Appalachian States. J. H. WATKINS. *Bull. Am. Inst. Mining Eng.* 1915, 391-411.—The paper gives a general description of the

occurrence and methods of mining and washing the white burning clays and a discussion of their economic value. The clays dealt with particularly are the N. C., Va. and Ga. kaolins or china clays (residual); the S. C. and Ga. kaolins or paper clays (sedimentary), and the Fla. and Tenn. plastic kaolins or ball clays (sedimentary). Tables of analyses are given. Illustrated. C. S. KINNIBON.

Drying of clay wares. ELLIS LOVEJOY. *Clayworker* 62, 389-90, 516; 63, 182-3, 538-9(1915); 5 figs.; cf. C. A. 8, 3714.—L. gives the general principles of a hot air periodical drier (Bechtel) which is extensively used in the U. S. and Canada. Tables and calcns. are given for the detn. of temps. available for steam coils when used in connection with drying clay wares. A problem is outlined for the detn. of the amt. of piping for any clay drier. Methods of drying terra-cotta products are described. An illustrated description is given of a 2-storied tunnel type drier and the Scott system of drying is explained. The purpose of the latter system is to eliminate the drier. L. writes on the conservation of heat in German factories, giving plan and sectional views of a German drier equipment, making extensive use of waste heat. The principles of the progressive driers are also given. ROBERT BACK.

The proper construction of hollow ware dies. ERNEST W. KNAPP. *Brick Clay Record* 46, 457-62(1915); 13 figs. ROBERT BACK.

A new method of steam lubrication. R. S. GANGEWERE. *Brick Clay Record* 46, 468(1915); 1 fig.—One steam pipe leads to the pug mill and another to the brick machine while the usual type of oil lubricator is attached to the die. R. BACK.

The manufacture of sewer pipe. ANTON VOGT. *Clayworker* 62, 273-4(1914).—V. tells how blued pipe, dark glazed and brown pipes are produced. He gives directions for the manipulation of the damper during the salt-glazing process. The "white" which sometimes appears on the finished pipes is explained by the deposition of undecomp. salt caused by too low a temp. during salt-glazing. ROBERT BACK.

Improvement on filter press plates. ANON. *Deut. Toepf. & Zieg. Z.* No. 51, 1914; through *Clayworker* 62, 292.—The plate consists of an iron frame with galvanized iron wire stretched in it and covered on both sides with a cement body. R. BACK.

A new and improved cutting table. ANON. *Brick Clay Record* 45, 707(1914).—Broken wires may be replaced while the machine is in motion. R. B.

A new clay washing device. ANON. *Brick Clay Record* 45, 814(1914); illustration. R. BACK.

Composition of portland cement mortars in sea-water. G. GEORGIS AND G. CARRU. Rome. *Ann. chim. applicata* 3, 168-81(1915).—G. and C. examd and

analyzed cement mortars from sea-water constructions built in 1886, 1888, 1893, 1897, and also from one that must have been centuries old. Making certain assumptions based on a review of old authorities and documents bearing on the original comp. of these mortars, and comparing the old with modern cement mortars, it is concluded: (1) that a part of the CaO of the mortar is eliminated, but this elimination ceases after a certain period of time, as the very ancient mortar does not differ much in this respect from some of those relatively recent; (2) as to MgO , there was found no noteworthy change in process of time; (3) that there is a marked tendency towards elimination or at least a large diminution in the quantities of alkalis; (4) that the ratio between SiO_2 and Al_2O_3 tends to decrease. The authors intend to undertake expts. permitting them to follow out from the beginning these changes in cement mortars.

S. LEVY.

Standardization of No. 200 cement sieves. R. J. WIG AND J. C. PEARSON. *Bur. of Standards, Tech. Paper 42*, 51 pp.—This paper discusses the results of a number of observations made to det. methods of standardizing the 200-mesh sieve and its manipulation so that greater uniformity may be obtained in its use. A study was made of: (1) the accuracy of sieving tests, personal equation in sieving, variations in sieving value of standard sieves and precautions required; (2) the results of sieving tests made in 85 different labs. and a comparison of these results with those obtained by the Bur. of Standards on some of the same sieves; (3) 4 proposed methods of standardizing sieves; (4) the suitability of a number of finely ground materials, as compared with portland cement, for use in calibrating sieves; (5) the adoption of a standard value of fineness; (6) the application of a "correction" to the sieving value of standard sieves; (7) a revised specification for standard sieves. Diagrams and tables are given.

C. S. KINNISON.

Blast furnace slag as aggregate in concrete. W. A. AIKEN. *Trans. Am. Soc. Testing Materials* 14, 280-97 (1914).—Concrete consisting of cement, slag, and New Jersey gravel was tested in compression at various periods up to and including 1 yr. From strength of concrete, wt. of slag per cu. ft., puzzolanic nature of slag, its alk. nature which is conducive to rust-prevention in reinforced concrete and from relatively high combined % of SiO_2 , Al_2O_3 , and Fe_2O_3 making for permanency in concrete, it is concluded that slag of similar constitution is satisfactory for use as aggregate in concrete. Analysis of slag gave in %: SiO_2 , 34.40; R_2O_3 , 23.40; CaO , 35.88; MgO , 3.21; SO_3 , 0.39; S, 1.27; ignition loss, 1.34.

J. D. PENNOCK.

The occurrence of chlorine in coal. A. DEWARLE. *Analyst* 40, 146-7(1915).—A case of abnormally rapid corrosion of boiler tubes was found to be due to the presence of sol. chlorides in the coal. Cl was detd. (1) by mixing a weighed amt. of the powdered coal with powdered lime in a Pt crucible, inverting the latter in a larger crucible, this being filled to within $\frac{1}{2}$ in. of the top with lime, and igniting in a muffle; after ignition, the material was dissolved in dil. HNO_3 , neutralized, and Cl titrated in the usual way; (2) by direct extn. of the powdered coal with water and titrating with AgNO_3 . Exam. of 6 samples of coal from the same sources as that used in the boiler showed the following min. and max. figures for Cl: By ignition, 0.018 and 0.344%; by extn., 0.019 and 0.346%. Five of the 6 samples contained 0.210% Cl or over. These figures indicate that the whole of the Cl is present as sol. chlorides. Exam. of 11 samples of coal used in a boiler in good condition showed Cl contents varying from 0.003 to 0.032%.

Coal resources of District VII (Illinois). FRE H. KAY, *et al.* Illinois Geol. Survey, *Bull.* 11, 233 pp.(1915). E. H.

Coal resources of District I (Longwall, Ill.). G. H. CADY, *et al.* Illinois Geol. Survey, *Bull.* 10, 144 pp.(1915). E. H.

The determination of volatile combustible matter. F. E. LATHE. *Chem. Analyst* 12, 5(1915).—Weigh 1 g. coal sample into an annealing cup or a porcelain crucible, cover well, placing sheet asbestos between cover and crucible if necessary to secure a close fit, and fasten on the cover with Fe wire. Place a little powdered charcoal in the bottom of an ordinary assay crucible (15 or 20 g. size) and place the small crucible contg. the sample on the charcoal. Fill the large crucible with powdered charcoal, cover with a scorifier, and place in a hot muffle ($1000-1200^\circ$) for 30 min. Remove, allow to cool undisturbed, and weigh the residue. Loss in wt., less the moisture is volatile combustible matter. H. M. LANCASTER.

Heating materials for military camp outfits. BRÜSTEDT. *Pharm. Ztg.* 60, 151-3(1915).—Expts. carried out to det. the relative efficiency of spirit, "hartspiritus," hexamethylenetetramine and "bewei" show that in point of cheapness spirit, of cleanliness $\text{C}_6\text{H}_{12}\text{N}_4$, of safety and convenience in shipment $\text{C}_6\text{H}_{12}\text{N}_4$ and "bewei" take first place. Eight g. combustible are required to bring 150 g. H_2O to the b. p. and maintain it there for a brief period. "Bewei" appears to consist of compressed plant fiber mixed with easily combustible substances.

W. O. E.

Improvements in firing construction for solid fuels. PRADEL. *Feuerungstechnik* 3, 157-162(1915); cf. *C. A.* 9, 961.—A review is given of recent improvements in firing construction including stokers for locomotives, ash removers, draft regulators, flue-ash and spark retaining apparatus, grates with automatic removal of clinker and smoke consuming apparatus. H. R. GUNDLACH.

Efficiency relation existing between various Argand and open flame test burners. F. H. GILPIN. *Proc. Am. Gas Inst.* 9, 379-405(1914).—Methods of detg. c. p. with 2 classes of burners are discussed in detail and 4 types of Argand burner are taken up and each type reviewed. It is shown that there exist differences in burners of the same class and types and that errors are more readily discovered and corrected in the open flame burner than in the Argand. Curves are given to show the effect of varying consumption on the c. p. of different types, also a comparison of various burners on coal, water and mixed gases. Values are given to show that the error due to variations of relative humidity on open flame burner is a "negligible amount." C. A. COLE.

Report of the committee on progress in carbonization methods. E. L. SPENCER. *Proc. Am. Gas Inst.* 9, 450-453(1914).—The report consists of an account of various types of carbonizing installations erected or partly completed during last year. C. A. COLE.

The mode of decomposition of coal by heat. H. C. PORTER AND G. B. TAYLOR. *Proc. Am. Gas Inst.* 9, 234-88(1914).—High grade bituminous coal of the gas making type is decomposed by heat primarily into paraffin hydrocarbons and completely altered non-volatile residue, with a small quantity of H_2O , CO_2 and CO . The latter products, though small, are the first produced and from other types of coal they are produced in greater relative quantity than from gas coal types. Complex and varied secondary reactions introduced by superheating the hydrocarbons, H_2O vapor and CO_2 , are of very great importance in industrial high-temp. carbonization. The products of low-temp. carbonization (at 800-900° F.) of a coal of the Pittsburgh type on an industrial scale would consist of a rich gas amounting to about 0.6-0.7 cu. ft. per lb. of coal and a large yield of heavy oils, or tar, (10-12% of the coal), made up chiefly of paraffin hydrocarbons very low in benzene and $C_{10}H_8$ derivs. and practically devoid of free C. The gas would contain 6-7% of unsatd. hydrocarbons and 20-25% of ethane and its higher homologs, having a high calorific and illuminating value. The tar might be distd. or cracked to produce light oils (gasoline substitutes). The possibility is suggested that low-temp. carbonization might be utilized in gas manuf. as an enriching process. Inferior coals might be thus utilized. Based on exptl. results of low-temp. decomp. *in vacuo*, the following hypothesis is proposed for the *constitution of coal*. All kinds of coal consist of cellulosic degradation products, more or less altered by processes of aging, together with derivs. of resinous substances in different proportions, also more or less altered. There is a large number of these substances and all undergo decomp. by a moderate degree of heat. The less altered cellulosic derivs. decompose more easily than the more altered derivs. and also more easily than the resinous derivs. The cellulosic derivs. decompose on moderate heating, yielding H_2O , CO_2 and CO and hydrocarbons, giving less of the first 3 products the more mature and altered they are. The resinous derivs. decompose on moderate heating, yielding chiefly paraffin hydrocarbons with H as a direct decomp. product. The more mature bituminous coals, having good coking properties, contain a large % of resinous derivs., and their cellulosic constituents have been greatly altered. The younger bituminous and sub-bituminous coals are constituted of cellulosic derivs. much less altered than those in older coals. They undergo a large amt. of decomp. below their fusion point and partly for that reason may not coke. The paper is illus. by a large number of sketches of app. used together with many tables, curves and other data. C. A. COLE.

Carbonization in bulk. Koppers' ovens. C. J. RAMSBURG. *Proc. Am. Gas Inst.* 9, 543-80(1914).—The paper deals with the fundamental principles involved in the carbonization of coal in bulk, its advantages, methods and results of plants in operation. Results are given of the operation of some of the European plants and a comparison is made with some American plants. The quality of gas, coke and tar is discussed and NH_3 yields of various coals and methods of operation are compared. C. A. C.

Care and maintenance of gas holders. J. H. BRAINE. *Proc. Am. Gas Inst.* 9, 762-875(1914).—The various theories of corrosion are taken up with especial reference to the attack on iron metal for illum. gas storage and transfer. The effect on different parts of the holder is noted and suggestions are made for the proper up-keep, together with a description of tools for removing corrosion products and a comparative test on a number of so-called protective coatings. C. A. COLE.

Purifier installations. C. E. PAIGE. *Proc. Am. Gas Inst.* 9, 721-62(1914).—P. briefly reviews the purification of gas by different processes and discusses the important points in the design of purifier boxes. A detailed description is given of the construction and operation of 4 concrete purifier boxes each 25 x 35 x 40 ft. deep with 20 in. connections. The paper also includes a series of questions sent out to a great number of gas companies concerning the operation of various types of purifiers. Replies include figures on cost of operation, efficiency, maintenance and labor charges. C. A. C.

Methods and facilities for specifying and testing blowers. Also measuring air and steam supply to the water gas generator. J. M. SPITZGLASS. *Proc. Am. Gas Inst.* 9, 615-77(1914).—S. gives an account of expts. made to det. the values necessary in designing blowers, together with tests with various types of instruments for measuring steam. Illustrated by sketches, charts, curves and other data. C. A. COLE.

The operation of inclined retorts. F. HUBER. *Proc. Am. Gas Inst.* 9, 406-50(1914).—The paper gives the experience of 13 yrs. operation of an inclined retort system at Louisville, Ky. The installation consists of 20 benches of 6's: 15 in. x 23 in. top; 15 in. x 26 in. bottom; and 18 ft. long, in 2 stacks (10 benches each) placed parallel. Illus. by sketches, tables, charts and other data of operation and labor cost. C. A. C.

Economical working of sulfate of ammonia plants and the quality of the sulfate. FREDERICK SHEWRING. *Gas World* 62, 465-6(1915).—S. discusses the ideal system of separate recovery of the fixed and free compds. of ammonia, the advantages of high testing sulfate, the financial aspect of efficient liming plants, prep. of lime and the continuous sight feed gravity liming system. A cut of the app. is given. M. L. T.

Simple determination of gases in flue gas. A. DOSCH. *Gesundh. Ing.* 38, 121-8(1915).—A modification of the Orsat app., in which stopcocks are eliminated as much as possible, is used. The app. is very compact. ARTHUR LEDERER.

Some notes on tar dehydration and benzene recovery. ROBERT BASS. *J. Gas Lighting* 129, 320-22(1915).—Sp. gr. may be detd. by means of a Lunge hydrometer. Distn. is carried out on 500 cc. of tar in a 750 cc. side neck distn. flask; fractions are collected as follows: up to 170°, between 170 and 270° and between 270 and 300°. The test for tar acids is made on the 170-270° fraction by extn. with NaOH soln., neutralizing with H_2SO_4 and reading vol. of tar "acids" separating. Free C is estd. by extn. of bituminous matter from a weighed portion of tar by C_6H_6 or CS_2 . C. A. C.

Dehydration of water-gas tar (at the Amsterdam Western Gas Works). ANON. *J. Gas Lighting* 130, 196(1915).—The centrifugal sepn. of water-gas tar (sp. gr. 1.05) and H_2O can be made to deliver, in one operation, tar containing less than 1% H_2O , if the tar be preheated by live or waste steam to between 60° and 70° for a 60% H_2O content, or to 95° or 100° for 90% H_2O content. B. W. GRIMES.

Kubierschky system of tar distillation. C. H. BORRMANN. *J. Gas Lighting* 130, 448-50(1915).—To distil off tar to an entirely hard, brittle pitch, without the use of a vacuum, in a continuous, safe process, there has been devised a column-like app. into which the tar is sent in a thin spray dripping down in a finely divided state in the interior, while from below a uniform flow of superheated steam is passed up to come in direct contact with the tar. With increasing distn. temp. the consumption of steam decreases, giving a high degree of economy. The distn. goes on in steps in a series of separate chambers so that the light boiling distillates are collected above, having sepd. from the residue liquid, and the hard pitch is left below. Several forms of app. have been designed for various purposes. *Advantages:* uninterrupted operation, elimination of fire danger, reduction of the boiling temp. through the use of steam, ability to reduce tar to pitch of any quality with one continuous process, dehydration of the tar is not necessary, the steam consumption is about 20 kg. for 100 kg. of tar. The figures on operating results and costs are believed to be highly satisfactory.

B. W. GRIMES.

The extraction of carboric acid from oils of the distillation of coal tar. W. MASON. *Mel. Chem. Eng.* 13, 293-4(1915); see *C. A.* 8, 3717. E. J. C.

The valuation and estimation of coke. THALER. *Feuerungstechnik* 3, 109-12 (1915).—Cokes for foundry and for blast furnace use are differentiated in practice but from a series of exams. were found to differ but little. Coke for foundries should be the largest and best pieces and should, as a rule, contain less moisture and S than blast furnace coke. A table showing the quality of coke demanded by the "Verein deutscher Giessereifachleute" is given and the high moisture content (5%) allowed is criticized by the author. The moisture content depends on the physical characteristics, and during transportation in rainy weather soft, porous cokes increase 2-4% in moisture, while harder cokes increase only 1-2%. P when present is practically entirely taken up by the iron, and hence should not exceed 0.04-0.05% in a good coke. In addition to the chem. comp. of the coke, the physical properties are taken into consideration in detg. a good or bad coke. T. classifies coke in 3 divisions, as follows: I. Silver-white lustre, sinewy structure, dense, firm, with a metallic ring, resistant to pressure; it should not break into small pieces on falling, and should contain not more than 8% ash, 3.5-4% moisture, and 0.8% S. II. Faint white to dark lustre, structure more bony and porous than I, less resistant to pressure and heavier than coke of class I; it should have not more than 10-11% ash, 8-9% moisture and 1.0-1.1% S. III. Lustreless, gray-black fracture, soft, breaking easily when struck; the individual coal particles are easily distinguished; it is highly porous and holds water tenaciously. It has a low density, 9.0-9.5% ash, 13-15% moisture, and 1.0% S. The importance of the method of taking samples of shipments, in order properly to det. the quality is emphasized.

H. R. GUNDLACH.

The soluble chlorides and total chlorine in some English cokes. STANLEY W. BRIDGE. *Analyst* 40, 143-6(1915).—Thirteen samples of English gas coke were found to contain from 0.013 to 0.262% sol. chlorides as NaCl, and from 0.039 to 0.499% total Cl as chlorides. A sample of metallurgical coke contained 0.007% sol. chlorides and 0.071% total Cl as NaCl, while a low-temp. canal residue contained 0.357% sol. chlorides and 0.918% total Cl. Lab. expts. were made as follows: (1) coal carbonized in a fire-clay crucible at 400-500°; (2) in a Pt crucible for 15 min. over a powerful Meker burner. The sol. and total chlorides, resp., calc. to the original coal are (in %) (1) *Canal*, 0.068, 0.987; low-temp. residue (volatile matter 10.77%), 0.357, 0.918; high-temp. residue, 0.123, 0.314; (2) *Canal*, 0.077, 1.141; low-temp. residue (volatile matter 7.79%), 0.192, 0.498; high-temp. residue, 0.068, 0.288; (3) *Coking coal*, 0.092, 0.525; low-temp. coke (volatile matter 13.08%), 0.140, 0.237; high-temp. coke (15 min)., 0.140, 0.237.

0.048, 0.094; high-temp. coke (90 min.), 0.048, 0.091. The following methods were used: *Sol. chlorides:* 15–30 g. of an av. sample crushed to pass a 10-mesh sieve were boiled with water for 1 hr. under a reflux condenser; the coke was then filtered and washed and the filtrate on cooling acidified with HNO_3 , followed by a slow addition of dil. KMnO_4 until the soln. was just permanently pink. Standard AgNO_3 soln. was then added, the AgCl filtered off, and the excess of Ag detd. by the Volhard method. The KMnO_4 is added to prevent blackening due to a reducing agent which is always extd. from the coke. *Total chlorine:* 2.5–5 g. of the coke were gently ignited with 3–6 g. of a mixt. of 1 part pure Na_2CO_3 and 2 parts pure CaO until the C was completely burnt, the mass being then boiled with water to which a little PbCO_3 was added to remove sulfides. After filtering, concg., if necessary, and acidifying with HNO_3 , Cl is detd. as above. The loss of Cl during ignition with Na_2CO_3 and CaO is negligible. That the % of sol. chlorides in the low-temp. residue is higher than that in the original coal is probably due to the fact that the sol. chlorides are not completely extd. from the original coal, while the mass is rendered more porous after ignition. P. B. DUNBAR.

Metallic iron in coke samples. J. R. CAMPBELL. *Colliery Eng.* 35, 538(1915).—Iron from grinding app. was the cause of discrepancy between actual and theoretical coke ash. C. recommends 40-mesh sample as fine enough. Pulverizing should be by impact strokes rather than rubbing. C. advises against removal of iron from sample with a magnet, because magnetic sulfides are removed at the same time. W. D. ESSES.

An analytical study of the principal systems of coke ovens and regenerative furnaces. C. BERTHELOT. *Rev. métal.* 11, I, 685–751(1914).—A comparative study of the principal systems of coke ovens and regenerative furnaces with a view to stimulating their more general use in France. In 1912 the French blast furnaces consumed 5,500,000 tons of coke, while the national production of the latter was only 2,600,000 tons. A critical review of the advantages and disadvantages of the principal types of furnaces is given and of their applicability to the conditions of various sections of the country. L. T. FAIRHALL.

Brit., 29, Jan. 1, 1914. R. FARRY. Purifying crude coal-gas by passing it through a cooler and then through a primary washer, in which it is treated with combined solns. of an alkali carbonate and NH_4OH . This treatment removes so much CO_2 and H_2S that no more and even less acid impurities will afterwards remain in the gas than will be sufficient to neutralize its NH_3 , and consequently will be removed with the NH_3 when the gas is further washed with weak ammoniacal liquor and fresh H_2O in secondary washers. The liquor from the cooler and secondary washers is treated with lime in a still to produce NH_3 . The liquor from the primary washer is treated in a still of the kind described in 337, 1914 so that the alkali carbonate and NH_4OH are regenerated for use in the primary washer, and the CO_2 and H_2S together with a trace of NH_3 driven off into a saturator, into which the NH_3 from the lime still is also passed. The gases from the saturator are either partially burned in a Claus kiln for S recovery or are burned in excess of air for obtaining H_2SO_4 . In a modification, the crude gas may be washed with alk. carbonate soln., then with NH_3 soln., each soln. being regenerated separately.

Brit., 228, Jan. 5, 1914. H. STEVEN. In agglomerating coal, etc., the material is subjected in a closed mold first to a light pressure to expel air, second to a higher pressure to expel fluids or liquids, third to a still higher pressure to render the body homogeneous, and fourth to a slight pressure to tighten up any cracks.

Brit., 304, Jan. 5, 1914. DELLWIK-FLEISCHER WASSERGAS GES. In the manuf. of water gas, air is supplied during the "blow," through tongues above the layer of coked fuel, the discharge of the combustion products taking place at the bottom. The steam for gasification is introduced at the bottom by a pipe, and the H_2O -gas and distn. products from the upper part of the fuel bed are taken off by a pipe at the top. Cf. C. A. 9, 1242.

Ger., 279,966, Nov. 22, 1912. H. KÜPPERS. Control of regenerative furnaces.

Ger., 280,849, Sept. 27, 1912. HOCHOFENWERK LÜBECK AKT.-GES. Purifying coke oven gases and purifying chlorinating liquors from roasted ore treatment. The coke oven gases contain H_2S in greater or less amt. In the treatment of pyrite cinder by chlorinating roasting, very dil. lyes are obtained which contain Cu and Zn salts, and which must be freed from these before being discharged. The coke oven process is coupled with the process of purifying these chlorinating liquors by conducting the gas into the liquors, whereby the H_2S and the metallic salts react. If the Cu is to be

sepd. from the Zn, the liquors are maintained acid until all the Cu has been pptd. CaCO_3 is added then, and the gas is passed to sep. the Zn as pure ZnS . The acid liberated in this pptn. of ZnS is neutralized in order to insure the complete pptn. of the Zn. If the lye contains other metals, such as Pb, Ni, Co, etc., these are pptd. and can be sepd. if this is desired.

F. M. ROGERS.

Benzene, alcohol, and mixtures of these liquids with petrol as fuels for internal combustion engines. W. WATSON, *et al.* *Inst. Automob. Eng.* Dec., 1914, Sep. 20 pp.; *J. Soc. Chem. Ind.* 34, 266-7(1915).—The question of carburation, particularly when starting, and in cold weather, with fuels such as C_6H_6 , alc., and some of the heavier brands on petrol, is of great importance, and tests have been carried out comparable with those on petrol (cf. *Proc. Inst. Automob. Eng.* 7, 35). *Benzene*: Material used became practically solid at -12° ; the first indications of crystn. occurred at -4° . The crystals at once sink in the liquid, and risk of choking the jet of the carburettor as well as that of impeding the flow of liquid, is incurred. Even if crystals do not sep., the viscosity of the liquid at low temps. may influence the supply of fuel. The viscosity of C_6H_6 increases at a greater rate than that of petrol, and in cold weather it is important to heat the jet of the carburettor, or any constriction in the fuel-supply service. A mixt. of 1 part of petrol to 3 of C_6H_6 starts depositing at -14° ; a mixt. of equal vols. of the 2 gives no deposit at -21° . It would be advantageous always to mix 30% of petrol with C_6H_6 . The knocking produced at low engine speeds when petrol is used as fuel is not observed with C_6H_6 . This appears to be due to the fact that the critical temp. above which the charge fires in a way resembling detonation rather than inflammation, is much lower for petrol. C_6H_6 added to petrol causes a marked increase in the critical temp., and an engine which knocks badly with pure petrol runs quite smoothly with a mixt. of equal vols. of C_6H_6 and petrol. When using less than 12 parts of air to 1 of C_6H_6 by wt. the deposit of C in the engine is excessive, and the efficiency is greatly impaired. If the mixt. is so adjusted that practically no CO is found in the exhaust gases, the C deposit is no worse than with petrol. *Alcohol*: Expts. were made with ordinary methylated spirit in a jet carburettor, a larger jet being used than in the case of C_6H_6 and petrol; it was found necessary to supply additional heat to the carburettor by passing a current through a wire wound round the pipe leading from the jet to the throttle. This was not altogether sufficient, and owing to the irregular vaporization of the fuel, irregular exhaust gas measurements were obtained. The mean effective pressures obtained with alc. were slightly higher than those obtained with either petrol or C_6H_6 , and increased more rapidly with the strength of the mixt. than in the cases of the other fuels. When using the strongest mixt., 6 parts of air to 1 of alc., the mean effective pressure was still increasing with the strength of the mixt., and 6% CO was found in the exhaust gases. This means that max. power can only be attained by appreciable loss due to incomplete combustion. Max. thermal efficiency, as also that at complete combustion, increases slightly from petrol to C_6H_6 and C_6H_6 to alc., and the temps. attained with the 3 fuels do not differ much, though those with alc. are a little lower than the others, which may account for the slightly higher thermal efficiency obtained with alc. Unless the vapor tension of the fuel in the cylinder is above a certain limit it is impossible to obtain an explosive mixt. This

difficulty may be easily overcome in the case of petrol, as owing to the presence of highly volatile constituents it is possible to flood the cylinder and so obtain an explosive mixt. With C_4H_{10} and alc. no such volatile compds. are present; hence starting difficulties are encountered in cold weather. Expts. with different liquid fuels were made in a closed vessel, and it was found that with a very volatile brand of petrol an explosive mixt. could be obtained at 0° and a pressure of 40 lbs. per sq. in. Air satd. with C_4H_{10} vapor below 1° at atm. pressure is incombustible, and at all temps. below 20° air satd. with alc. vapor is incombustible even at atm. pressure. These results, together with others obtained from mixts. of these liquids, are shown graphically. When used in the engine the heat generated by the compression produced by starting the engine by hand is sufficient to vaporize the fuel, except, perhaps, in the case of alc., or, when the fuel is already vaporized, to keep it in the form of vapor during the compression.

F. W. SMITHER.

Illuminating power of kerosene. WILLIAM KUNERTH. Iowa State College. *Lighting J.* 3, 28-33(1915).—Tests were made on 61 samples of kerosene obtained from various sources to det. what relation existed between the illuminating power and the other properties. The illuminating power was detd. by burning the oil in a flat wick burner and measuring the c. p. in the direction perpendicular to the plane of the flame. This c. p. was multiplied by an exptly. detd. const. to obtain the m. s. c. p., the same const. being used for all tests. Early in the work it was found that the illuminating power in m. s. c. p. hrs. per gal. reached a max. value when the flame was burned at a certain optimum height, which varied with different samples and with outside conditions. The detns. of c. p. were made with the flame at the optimum height as nearly as possible. To make allowance for variable atmospheric conditions, the same standard sample was tested every day, and a correction derived from its performance, applied to the other tests. The illuminating power is expressed in m. s. c. p. hrs. per gal. in all of the results. The values for phys. properties are in some cases expressed in arbitrary units. The 2 sets of values given below are the averages, resp., of the 10 lowest and the 10 highest results. The illuminating power decreased as the cost increased, being 1114 at 10 c. and 1019 at 20 c. per gal. It increased as the d. increased, being 953 at d. = 0.791 and 1113 at d. = 0.821; increased as the temp. of the flash point increased, as follows: 1033 at 104° and 1116 at 124° ; increased as the temp. of the burning point increased, being 992 at 136° and 1109 at 158° ; increased as the viscosity increased, 1025 at 151 sec. and 1112 at 208 sec.; increased as the surface tension (as detd. by drop wts.) increased, being 980 at 3.096 and 1111 at 3.244; increased as the index of refraction increased, being 980 at 1.444 and 1120 at 1.463. The fogging of the chimney was slightly greater with oils of higher d. The charring of the wick was slightly less with oils of higher illuminating power. One sample was exposed to daylight for 6 weeks and thereby lost 15% of its previous illuminating power. In general Eastern oils have lower illuminating power, lower d. and higher cost, while Western oils have higher illuminating power, higher d. and lower cost. The results of all tests, along with several diagrams, are given.

A. B. GLADDING.

Preliminary report on the bituminous sands of northern Alberta. S. C. ELLS. Canada Dept. Mines, *Publ.* No. 281, 88 pp.(1914).—The bituminous sands of Alberta commonly referred to as "tar-sands," outcrop at a number of points along the Athabaska River and its tributaries. This area is probably not less than 750 sq. miles. These bituminous sands represent the Dakota sandstones and were originally in the form of soft sandstones and uncompacted sands, but subsequent impregnation by heavy asphaltic hydrocarbons has resulted in the present coherent material. Variation in the physical character and chem. comp. of the contained bitumen is due to the fact that the original petroleum varies over so extensive an area. Medium grained and

moderately compact deposit is usually the richest in bitumen. A bituminous sand that will comply with standard paving specifications should possess a certain grading of mineral aggregate and a suitable percentage of bitumen. Where the grading of mineral aggregate is not satisfactory, it is possible to obtain the desired grading by combining 2 or even 3 separate out-crops. Three sections involving a distance of about 170 miles on both sides of the Athabasca River and its tributaries were examd. Analyses of some of the bituminous sands from out-crops showed on the average 1.3% moisture, 18.5% bitumen sol. in CS_2 , 80.2% sand. The extd. bitumen contained 39.6% satd. compds. in the 88° naphtha soln. and 60.4% unsatd. compds. in the same solvent. The d_{20} of the ext. was 1.018 and upon analysis showed 7.23% fixed C, 4.85% S, and was sol. in 88° naphtha to the extent of 78.2%. When the extd. bitumen was submitted to distn. until coked, it was found that 69% of the original bitumen distd., leaving a coke residue of 23.7% and suffering a loss of 7.3% of uncondensed fractions. The bitumen contained in Alberta sand has too high a penetration factor; this must be modified by heating and fluxing before it can be used for asphalt work. After modification by heat, this bituminous sand is less susceptible to temp. changes. This is the result of the removal of the more volatile hydrocarbons as well as the oxidation of some of the bitumen. This hardening is carried out by heating the bitumen and MnO_2 or Fe_2O_3 to a temp. of 200° and then introducing some water and stirring. The water serves to keep the mass stirred by its transformation into steam and also to help the distn. by reducing the pressure with its own partial pressure. R. L. SIBLEY.

Bituminous shales of Colorado. G. R. DEBEQUE. *Eng. Mining J.* 99, 773-4 (1915).—Mainly a brief review of the work of Day and Woodruff (*C. A.* 8, 2664). "From the results of exptl. tests it seems probable that the Col. shale, at the lowest estimate, should equal in value the Scotch and French shales from which petroleum has been manufd. for so many years." F. W. SMITHER.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Advances in the chemistry of cellulose (1913-1914). EMIL HEUSER. *Papier Ztg.* 40, 307-9, 355-6, 379-80(1915).—Review of the more important researches in pure chemistry. V. NUNEZ.

Determination of the "ripeness" of viscose. V. HOTTENROTH. *Chem. Ztg.* 39, 119-21(1915); *J. Soc. Chem. Ind.* 34, 274(1915).—Cellulose xanthate, in soln. as viscose, undergoes dissociation or hydrolysis on storage, with ultimate reversion to cellulose. The progress of this reaction is termed "ripening" and is usually measured by differential titrations with I, after adding HCl to one portion and AcOH to another; the difference represents the alkali combined as xanthate in the compd. XO.CS.SNa, and is proportional to the degree of esterification at any given stage. Since the detn. of this factor in works practice is not of the simplest order, and since the industrial importance of "ripeness" relates almost solely to the speed of coagulation of the viscose, H. has devised a rapid titrimetric method based on direct coagulation with 5% AcOH or preferably with 10% NH₄Cl or (NH₄)₂SO₄ soln.; dil. 20 g. of the viscose with 30 cc. of H₂O and titrate with 10% NH₄Cl at a standard temp. until coagulation takes place. The method is empirical and the best proportions of H₂O and viscose may be selected according to the alkalinity of the viscose, % of cellulose, and saline by-products. The NH₄ salt is preferable to AcOH as the coagulating agent, being less affected by small accidental variations in the amt. of caustic alkali present. The interpretation of the results must be founded on empirical observations to det. the optimum condition of "ripeness" for practical working. F. W. SMITHER.

The status of the celluloid industry during the war. M. L. *Kunststoffe* 5, 85 (1915).—A brief discussion. F. W. SMITHER.

Apparatus for measuring the glaze of papers. L. R. INGERSOLL. *Z. Beleuchtungs-w.* 21, 9(1915).—The characteristic property of glass surfaces which at an angle of 57.5° polarize reflected light has been found to hold for the surface of glazed papers. The polarization on such surfaces amounts to more than 99% of that produced by glass. With the instrument described the fraction of the light is measured which is reflected below 57.5°, the light being polarized when it strikes the paper at a similar angle. The absolute glaze is not measured but the fraction measured of the total light, is assumed to be glaze, since the legibility of a printed surface depends more on the relative proportion of the glaze to diffuse reflection than on the absolute amts. of these 2 factors. The % glaze does not depend upon the strength of the illumination as this is strongly influenced by the strength and character of the light source. It is necessary to use a definite form of illumination to which all measurements are referred. The instrument is described in detail. W. H. S.

The obtaining of turpentine and resinous products in the manufacture of paper pulp. A. LUTTRINGER. *Mah. grasses* 8, 4276-9(1915).—A continued article in which

are described 3 methods for the extrn. of the resins from the wood, depending upon the agent employed: steam, alkalis and resin solvents. The residue is made up into paper pulp, and the turpentine is obtained as a by-product by boiling the wood with solvents containing Na_2SO_4 .

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Old and new facts concerning priming compositions. A. STETTBACHER. *Z. ges. Schiess-Sprengstoffw.* 9, 341-4 (1914).—A general discussion of the properties of detonator or primer comps. in which special attention is called to the fact that theories derived from the behavior of ordinary brisant explosives cannot always be applied to this special class of primary explosives. The various theories to explain the action of

Hg fulminate are discussed at length. Comparison of Hg fulminate with picric acid and 75% dynamite fail to show cause for the great superiority of the former in producing detonation in other explosives. This effect is apparently due to the sudden production of an enormous pressure, which, however, cannot in the case of Hg fulminate be shown to result from either high rate of detonation or evolution of heat. It is possible that the course of explosion of endothermic explosives such as Hg fulminate is different from that of the ordinary exothermic brisant explosives. A comparison of calcd. values for explosion temp., pressure, "work-density," and density of loading, of fulminates of Hg, Ag and Cd with similar values for the azides of Hg, Ag, Pb and Cd, fails to show any reason why the azides should be superior to the fulminates in detonating efficiency, yet actual detns. of the minimum wts. of these substances which will produce detonation of various nitro-substitution compds. show the decided superiority of the azides. These practical tests show Ag fulminate to be a much better detonator than Hg fulminate while the calcd. consts. indicate that the former should be inferior. The prep. and properties of $\text{Pb}(\text{N}_3)_2$ are discussed and this substance compared with Hg fulminate as regards sensitiveness to heat and impact, stability in storage, decompn. on exposure to sunlight, action on metals, etc. The azides do not alter appreciably in sensitiveness from exposure to sunlight, although they darken in color. Wet fulminate of Hg corroded Cu, brass, Fe, Al and Sn quite rapidly while wet $\text{Pb}(\text{N}_3)_2$ acted only slightly on Cu, brass and Al, and had no effect on Sn and Fe. Tests showed that $\text{Pb}(\text{N}_3)_2$ does not lose in detonating efficiency when compressed at pressures as high as 10,000 kg. per sq. cm., while Hg fulminate and its mixts. with KClO_3 lose much of their brisance when compressed at more than 700 kg. per sq. cm. One % of H_2O in Hg fulminate greatly lessened its effects, while 5% H_2O did not diminish the effect of $\text{Pb}(\text{N}_3)_2$. Several organic compds. more recently proposed for use as detonators (nitrobenzenediazonium perchlorate and hexamethylenetriperoxidediamine) are briefly discussed. These are said to be much superior to Hg fulminate in detonating efficiency.

C. G. STORM.

Velocities of flame in mixtures of methane and air. II. ALBERT PARKER. Birmingham. *J. Chem. Soc.* 107, 328-37(1915); cf. *C. A.* 8, 2483; 9, 378.—The influence of the diam. of the explosion tube was investigated, using the same app. as before. The max. velocity was obtained with about 10% CH_4 , and this increased rather rapidly with the diam. of the tube from 2 to 14 cm., then slowly, apparently reaching a max. beyond which the walls of the tube were without influence at about 16 cm. By a variation of the type of spark it was possible to increase the initial velocity from 84 to 98.9 cm. per sec. With a still more powerful spark velocities as great as 113 cm. per sec. might be attained. In order to obtain normal initial velocities of flame in mixts. of CH_4 and air, it is necessary that the source of ignition should give no impetus to the propagation. There is evidence that an elec. spark induces a sharper initial inflammation in gases than other modes of ignition (adiabatic compression) and it is possible that the initial inflammation induced by a spark will always travel above "normal" velocity.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The coloring matter of tree moss. ALFRED EDGE. *J. Soc. Dyers Colorists* 31, 74-5(1915); cf. C. A. 8, 3369.—The coloring matter of tree moss, although giving brown shades similar to the ordinary dye lichens or crotches, possesses only $\frac{1}{4}$ the coloring power and exhibits very interesting differences. The color from tree moss is fixed on wool almost as quickly as an acid color, but the color changes from yellow to orange brown upon long boiling. The yellow color obtained possesses excellent fastness to scouring and milling and great fastness to alkalies and upon treatment with metallic salts gives pleasing shades of brown, but it does not appear suitable for dyeing on mordants. Fastness to light is fairly good. This yellow color of tree moss is interesting in that it is, with the exception of turmeric, the only natural direct yellow known.

The use of bacterial rusts of flaxseed for determining fiber and waste of flax stems. E. A. DOMRACHEVA. *Russ. J. Expt. Landw.* 14, 155-66(1913).—A method for determining fiber, etc., in flax stems by use of a pure culture of bacterial rust is described in detail.

WM. P. GARRETY.

Fibers from various sources. ANON. *Bull. Imp. Inst.* 13, 20-4(1915).—Results are given of the chem. and phys. exam. of well known fibers from new sources: hemps from Egypt, Rhodesia and the Solomon Islands and *Hibiscus cannabinus* fiber from Rhodesia.

L. G. C.

Deterioration of canvas due to molds. F. GUEGEN. *L'union pharm.* 56, 55(1915); *Pharm. J.* 94, 357(1915).—The black spots and patches which tend to develop on tent cloth and sails when exposed to damp air and cause rotting of the fibers as if by H_2SO_4 , are due to the growth of molds, especially 2 species, *Pleospora infectoria*

and *P. herbarum*. The spores of these molds are rarely air-borne; they occur in the tissues of the textile fiber. Their presence may be shown by dipping the lower end of a strip of the cloth into sterile H_2O in a germ-free tube and incubating at 22° for 48 hrs. Bleached cloth is freer from living spores than unbleached. Waterproofing by immersing first into a 1:5 soap soln., then into a bath of 8% $CuSO_4$ tends to prevent subsequent growth. Probably sterilizing by dry steam under pressure for a short time will also protect the goods. S. WALDBOTT.

A new instrument for measuring the impermeability of cloth. N. WOJNESSENSKY. *J. Soc. Dyers Colourists* 31, 50(1915).—There are 2 ways of measuring the degree of impermeability: (1) making the cloth into a bag and measuring the time it takes water to percolate through; and (2) measuring the height of a column of water supported by the cloth before water drops through. The second method is quicker and more reliable; the instrument described is based on this principle. Also in *India Rubber J.* 49, 602 (1915). I. A. OLNEY.

Color and constitution (BALY) 2. Textile soft soaps (K. O.) 27. Substitutes for castor oil for the textile industry (HERBIG) 27. Catalytic reduction of indigo and vat dyes (BROCHET) 10. Organic chemical industry in Gt. Britain (PERKIN) 10.

U. S., 1,137,434, Apr. 27. P. F. VOGEL. Making a textile fabric by twisting together natural silk in the gum and artificial silk or cotton, knitting or weaving the composite threads, degumming the silk by boiling in a soap bath and then dyeing in a bath which will color the cotton or artificial silk but not the natural silk and finally boiling to remove any dye which may have adhered to the natural silk. Degumming after weaving gives the fabric a crinkled or wavy appearance.

U. S., 1,137,501, Apr. 27. M. LINFOOT. Ornamenting artificial silk or other textile fabrics by placing the fabric on a pattern fabric, which is supported on thick cloth or other pervious material and passing steam through the 3 superposed materials.

U. S., 1,138,670, May 11. G. KRÄNZLEIN, R. HAGENBACH and F. GILOY. Arylaminoanthraquinone dyes are made by nitrating the oxazole obtained from β -aminoalizarin and $BzCl$, *o*-chlorobenzoyl chloride, benzoin or bromoacetophenone, condensing the nitro compd. thus obtained with aniline, *p*-toluidine or other aromatic amine and sulfonating the condensation product.

U. S., 1,139,326, May 11. J. BARRINGTON. Alkali-free dye soap is made by boiling a neutral vegetable oil soap, castor oil and H_2O in the proportions of 16:2:16 parts, adding an aniline dye which will color both vegetable and animal fiber, *e. g.*, "substantive black," boiling the mixt. and then cooling it.

Brit., 29,359, Dec. 20, 1913. H. LEVINSTEIN and LEVINSTEIN, LTD. Obtaining fast prints on vegetable fiber by applying a printing paste containing a non-substantive azo dye capable of forming an insol. compd. with $HCHO$, and subsequently treating the print with $HCHO$; the treatment with $HCHO$ may precede or follow, or form part of the steaming operation; *e. g.*, $HCHO$ or a substance capable of yielding $HCHO$ may be printed on before steaming, or $HCHO$ spray or vapor may be mixed with the steam. Cf. C. A. 8, 2624.

Brit., 29,479, Dec. 22, 1913. B. LEECH. Treating textile fibers, before dyeing with basic dyes, first with an acid and then with a soln. of a silicate, such as Na or K silicate; tannic acid or other tannin materials, such as sumac or gall ext., are suitable acids. The process is particularly applicable to the fixation of basic dyes on cotton or art. silk or mixed fabrics containing cotton and art. silk. According to an example, such a mixed fabric is treated first with tannic acid, then with Na silicate soln., then

dyed by means of methylindone B and methyl violet 6B in presence of HCO_2H , and finally passed through a Na silicate bath. The Na silicate, if alk., is neutralized by HCl. Material dyed with indigo or other vat dyes may be after-treated first with tannic acid, then with Na silicate soln.

Brit., 29,512, Dec. 22, 1913. A. E. GARRETT. Treating wool and woollen fabrics to reduce their tendency to shrink, by means of the ordinary "unshrinkable" bath, and then in a comparatively weak bath of NH_3 and soap soln. to reduce the readiness with which they will otherwise absorb moisture. The goods, after passing through the first bath, may be passed through a clearing-bath, and are then immersed for a few mins. in a bath containing from 4 to 15 cc. of strong NH_3 per l. of soap soln. The goods may then be scoured and rinsed. White goods should preferably be bleached by oxidation after this treatment.

Brit., 29,852, Dec. 29, 1913. E. LODGE and J. M. EVANS. In dyeing union goods with sulfur dyes, Na or K sulfite is added to the hydrosulfite vats.

Brit., 30,055, Dec. 31, 1913. ANILINFARBEN- & EXTRACT-FABRIKEN v. J. R. GRIGY. The diazo compds. of arylsulfonic esters of aminophenols or their substitution products are employed in the production of azo and primary and secondary disazo dyes; the azo dyes from the arylsulfonic esters of *o*-aminophenol and its substitution products are excluded. Some of the dyes specified may be employed in the production of lakes.

Brit., 201, Jan. 3, 1914. G. STONE. App. for drying wool, etc., comprizes a support for the material, to which an evapg. agent is supplied, the supply being automatically cut off when the wt. of the material is sufficiently reduced.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Rapid test for the fineness of paint pigments. C. D. HOLLEY AND J. C. BRIER. *Oil, Paint and Drug Rep.* 87, 32H(1915).—The authors have succeeded in procuring satisfactory screens of 350-mesh. A 25 g. sample of the pigment is washed through the screen under the water tap, using a soft 1 in. brush to break up the lumps, brushing continually until only the coarse particles remain on the screen. The residue on the screen is dried and weighed. When abrasive pigments, such as silica and oxides of Fe, are tested, the amt. of service from a screen is limited and after 100 detns. the screen should be checked against a standard screen, reserved for that purpose. E. W. B.

Lessons from the 1906 test fence. E. F. LADD AND W. F. WASHBURN. N. Dakota Agr. Expt. Sta., *Paint Bull.* 1, 73-9(1915).—In mixed paints the addition of color considerably improved the wearing quality, and the darker colors showed better wearing qualities than the lighter. The character of the lumber influenced to a large extent the lasting qualities of the paints (ordinarily applied), soft pine being far better than hard pine or even than western cedar or fir. Test fences will by the end of 3 yrs. show about the same condition for av. paints as tests made on houses at the end of 5 yrs. Properly conducted fence tests constitute the most practical and satisfactory method yet devised for studying the wearing qualities of paints. Check tests should be made on houses. Substitution of benzine for turpentine does not appear to give the same results as in the cases where turpentine in moderate amts. is used. Sublimed lead has not been found inferior in wearing quality to basic carbonate white lead. The indications are that basic carbonate white lead chalks earlier than sublimed white lead, and that sublimed white lead chalks more and continues longer than basic carbonate white lead. Reproduced photographs of many panels are given. E. W. BOUGHTON.

Analyses of mixed paints. E. F. LADD AND W. F. WASHBURN. N. Dakota Agric. Expt. Sta., *Paint Bull.* 1, 85-108(1915).—Reports of analyses of various mixed paints on the market, giving label, brand and manufacturer. E. W. BOUGHTON.

Method of varnish analysis. R. W. DARNER. N. Dakota Agric. Expt. Sta., *Paint Bull.* 1, 108-111(1915).—D. points out the errors in several previously published methods and proposes the following procedure: Spread out 3-4 g. of varnish on an Adams filter coil, which has been dried and weighed with an extraction thimble. Coils and thimble must be weighed in a weighing bottle. Hold the coil in the mouth of a weighed 300 cc. Erlenmeyer flask and add slowly 100 cc. of petroleum ether (d. 0.670). A large portion of the varnish is washed out of the coil by this treatment. Place the coil in the extn. thimble and ext. for 36 hrs., or until extn. is complete. Add 150 cc. of petroleum ether to the contents of the flask and cool to 3°, until the gums settle and the liquid is clear. Pour off the liquid containing the oils and rosin and wash the gums several times with petroleum ether. The flask and thimble are dried at 105° to const. wt. The increase in wt. represents the wt. of the hard gums present and the metallic driers. Saponify the petroleum ether ext. with 0.5 N alc. KOH and ext. the unsaponifiable matter with ether. Add HCl to the soap soln. and ext. the fatty and rosin acids with ether. After distg. off the ether, det. the rosin by the Twitchell method. When Chinese wood oil is present, the polymerized portion is pptd. by the petroleum ether, but this ppt. does not stick to the flask as do the gums. The method depends for its accuracy on using the proper fractions of petroleum. Tables of results show the method to be very accurate. E. W. BOUGHTON.

The use of clays for paint manufacture. J. J. KOCH. *Clayworker* 62, 508(1914).—K. describes the manuf. of ochers, Venetian red, umbers and sienna paint pigments. Preheating and subsequent washing of certain clays removes sol. salts and produces clays of good value for painters' use. R. BACK.

U. S., 1,137,374, Apr. 27. J. W. AYLSWORTH. Varnish or enamel formed of a phenol resin free from uncombined CH_2O mixed with 4-10% its wt. of hexamethylene-tetramine, both dissolved in a volatile solvent, e. g., MeOH, EtOH or acetone.

U. S., 1,137,467, Apr. 27. A. EIBNER. Producing a light pigment from cinnabar or other ores containing mercury sulfide by treating the ores with K_2S soln. to form a soln. of $\text{HgS.K}_2\text{S.5H}_2\text{O}$, allowing the soln. to cool and introducing it into a cold, satd. soln. of liver of S and S to form black mercuric sulfide and K sulfides and heating the mass on a steam bath for 12-24 hrs. or until it assumes the desired color.

U. S., 1,139,427, May 11. R. B. LLOPART. Preparing an inalterable white pigment (lithopone) by treating a pure ZnSO_4 soln. with an aq. soln. of BaS , drying the ppt. and calcining it out of contact with air at 500-700°, chilling in H_2O , grinding, washing, heating to 80-100°, pressing and rapidly drying at about 80-100°.

Brit., 29,889, Dec. 29, 1913. A. NEFGEN. In transferring pigment prints to metal surfaces, the surface of the metal is moistened, and the tissue is applied in a dry state, whereby dragging of the print is avoided.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Bromides of fatty acids. MITSUMARU TSUJIMOTO. *Chem. Rev. Fett. Hars. Ind.* 1914; *Pharm. Zentralkalle* Jan. 21, 1915; *Pharm. J.* 94, 321(1915).—The quantity and the properties of the Et_2O -insol. bromide (octobromide) obtained from the fatty acids of train oil are influenced by the solvents used in the bromination. With

glacial AcOH, the bromide is gelatinous; with Et₂O, it is cryst. and the yield is greater. When mixts. of solvents are used, the yields and properties of the bromides are more or less influenced by each of the solvents. A table of bromides is given (in the original article) obtained from various train oils. The bromide standard of the bromide obtained from Japanese sardine train oil, with a mixt. of glacial AcOH and Et₂O as a solvent, was 70.12-69.79.

S. WALDBOTT.

The pharmacopeia test for the presence of sesame oil in olive oil. CHARLES E. SAGE. *Pharm. J.* 94, 128-9, 193(1915).—Baudouin's test adopted by the Brit. Pharm., 1914, excludes reliably pure olive oils. Many pure Spanish oils indicate at most 1% sesame oil by this test and are thereby excluded. Whatever else may be abnormal with a sample in showing the test, the cause is not the presence of sesame oil. With Villavecchia and Fabri's modification, no color in 10 min. shows absence of sesame oil; but pink in 10 min. does not prove its presence, since some genuine olive oils give a pink layer changing to lilac-blue lasting 1 hr., then turning dark olive green or brown.

S. WALDBOTT.

Some considerations affecting the growing of linseed as a farm crop in England. I. Variations in oil content. J. V. EYRE AND E. A. FISHER. *J. Agr. Sci.* 7, 120-34 (1915).—The authors confirmed the work of Ivanov (cf. *C. A.* 6, 1170) who proved that there is little difference in oil content of seed from the fiber crop and that from the linseed crop. The oil content of the seeds reaches nearly the max. value several weeks before the seeds ripen. A comparison of the oil content of several varieties of imported seed with the oil content of seed produced from them in different parts of England, showed close agreement. Of the 4 varieties used, Plate showed itself to be most profitable, Steppe, Moroccan, and Dutch following in order given. The larger seeds contd. a higher % of oil than the smaller ones. Repeated growth from the same stock of seed showed no diminution in the oil content while art. fertilizers had no appreciable effect on it.

O. F. MILLER.

The seeds of *trichilia* from the Nigerian Sudan. P. AMMANN AND J. VUILLET. *Agron. coloniale* 2, No. 14, 34-6(1914); *Bull. Agr. Intelligence* 5, 1593(1914).—The various species of *Trichilia* have not yet been thoroughly investigated, although they yield various interesting products; the bark of some of them is an excellent substitute for ipecacuanha, while their seeds contain varying quantities of fatty matter suitable for soap and candles. Six species are reported from West Africa proper and 6 from Equatorial Africa. The seeds of *T. emetica* have been exported from Mozambique to Marseilles for a long time under the name of "Mafuraires." To det. whether or not the W. African products gave seeds of equal value, seeds from various species found between Bamako and Koulikoro were studied. Types: (a) small, dark red seeds; (b) medium-sized seeds of orange vermilion color; (c) large, orange-colored seeds. Analyses of seeds: wt. of 100 seeds, g. (a) 12.7, (b) 29.4, (c) 79.1. Wt. of 100 kernels, g.: (a) 4.68, (b) 17.08, (c) 46.04. Percentage of kernels in seeds: (a) 36.9, (b) 58.1, (c) 58.2. Shells, %: (a) 63.1, (b) 41.9, (c) 41.8. Moisture in shells, %: (a) 6.42, (b) 4.16, (c) 4.74; in kernels: (a) 5.73, (b) 6.71, (c) 5.76. Fat in shells: (a) 41.50, (b) 38.10, (c) 51.90; in kernels: (a) 30.1, (b) 44.7, (c) 43.7. Analyses of the fats: *d* = fat of kernels from *b*; *e* = fat of kernels from *c*; *f* = fat of shells from *c*. Color: *d* and *e* light brown, *f* lighter brown. Solidification pt. of glycerides: *d* 18-19°, *e* 15-16°, *f* about 13°. Acidity % as oleic acid: *d* 5.60, *e* 2.82, *f* 3.05. Fixed insol. fatty acids, %: *d* 92.0, *e* 90.3, *f* 92.0. M. p. of insol. fatty acids: *d* 52°, *e* 51.5°, *f* 44°. Glycerol: *d* 6.3, *f* 5.8. The large seeds most nearly approach the "Mafuraires" from Mozambique as regards size and fat content. The medium seeds are identical with those of *T. prieureana*. French W. Africa should be able to export at least several hundred tons of the "Mafuraire" seeds each year.

F. W. SMITH.
Digitized by Google

Can substitutes for castor oil be used in the textile industry? W. HERBIG. *Seifenfabr.* 35, 277-9(1915).—The chem. constitution of castor oil makes it doubtful whether there is available any real substitute which does not contain a considerable amt. of hydroxy-fatty acids of the type found in castor oil. Oils contg. oleic acids and fatty acids with more than 2 double C bonds when sulfonated produced Turkey red oils which are not usable. A mixt. of $\frac{1}{3}$ linseed and $\frac{2}{3}$ castor oil gives a cloudy soln. after sulfonation and neutralization with NH_4OH . By treating linseed or olive oil with 1% of osmic acid and H_2O_2 it is possible to reduce the I nos. of these oils to 0, and to make them sol. in alc. and in dil. alkali solns., but the cost would be too great for com. purposes. It appears that the most likely raw materials for substitutes are rape, fish and olive oil. E. SCHERUBEL.

Sulfonated naphthenic acids. J. DAVIDSOHN. *Seifensieder Ztg.* 42, 285(1915).—D. could not obtain a sulfonated product by the method described by Lidov (given). He found the following procedure successful: To 100 g. of the acids, 300 g. of fuming H_2SO_4 are slowly added and the mixt. allowed to stand overnight. The next day it is washed with a NaCl soln. until free from SO_4 . A dark-colored oil results which forms a fairly permanent emulsion with H_2O . The SO_4 content is about 7%, and the odor is disagreeable. E. SCHERUBEL.

Purification of soap lyess. B. LACH. *Seifensieder Ztg.* 42, 256-7(1915).—An Fe compd. known as "Persulfat" is being used as a substitute for $\text{Al}_2(\text{SO}_4)_3$ in purifying lyess. It is especially efficient in pptg. As. It is used as follows: The lyess are neutralized with acid at 90° to a point a little on the alkaline side, when the fatty acids sep. and are skimmed off. The lye is then brought to boiling and the "Persulfat" in colloidal soln. added a little at a time. The soln. is tested after each addition to see when pptn. is complete. The lye is next filtered and the acidity of the filtrate neutralized with $\text{Ca}(\text{OH})_2$ or $\text{Ba}(\text{OH})_2$, preferably the latter because Ca tends to remain in the glycerol. The evapn. of the lye is carried out in 2 stages; in the 1st it is brought to $22-4^\circ$ Bé. and allowed to cool in order to cryst. out NaCl. It is then evapd. to whatever density is desired. E. SCHERUBEL.

Textile soft soaps. K. O. *Seifensieder Ztg.* 42, 235-6(1915).—The following formulas are being used in Germany during the war: Bleached sulfonated olive oil 400 kg., linseed oil fatty acids 100 kg., bone grease fatty acids 500 kg., 50° Bé. KOH 400 kg. and K_2CO_3 80 kg. This soap is improved by adding artificial color. A green soap is made from green sulfonated olive oil 750 kg., linseed oil fatty acids 150 kg. and bone grease fatty acids 100 kg. In spring and fall 5% NaOH may be added to the KOH and 15-20% in summer. E. SCHERUBEL.

Oil from dog fish (YOUNG) 15. Hardened fats as foods (THOMS) 11E. Hard greases (FAUST) 29.

U. S., 1,138,201, May 4. C. ELLIS. Hydrogenating cottonseed oil or other oils or fats by the addition of Ni carbonyl and H or water gas and heating to about $150-200^\circ$ to decompose the carbonyl and effect hydrogenation by the combined action of the H and reduced Ni. During the latter part of the process the temp. of the material is reduced to about $85-125^\circ$.

U. S., 1,138,230, May 4. J. LEIMDÖRFER. Making hard paste soaps by adding Turkey red oil or other sulfonated oil to olive oil, tallow or other fatty soap stock to increase the resisting capacity of the alkali salts, subsequently formed from the fatty acids, in aq. solns., and then completely saponifying with an alkali soln. of $30-40^\circ$ Bé.

Brit., 21,853, Sept. 27, 1913. R. Russ. Sulfonated oils and fats are sepd. from the excess of acid used in the sulfonation process by the addition of a quantity of H_2O or salt soln., and subsequent treatment in a centrifugal machine. Products are obtained which have a high resistance to the action of acids and of Ca and Mg salts. They yield clear solns. with hard or soft H_2O either in a neutral or strongly acid condition.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

History of sugar. ANON. *Louisiana Planter* 54, 206-7, 270(1915).—Continuation of previous articles (cf. C. A. 9, 532 and 1130), covering periods from 1527 to 1581 and from 1582 to 1763.

A. GROSS.

Cupropotassic solutions, Barreswill's and Fehling's solutions. H. PELLET. *Bull. assoc. chim. suc. dist.* 31, 978-81(1914).—A brief history of the development of alk. Cu tartrate solns. for the detn. of reducing sugars. In 1843, Barreswill announced the use of $CuSO_4$ and alk. tartrate solns. for the detn. of reducing sugars. In 1849, Fehling perfected the proportions of the salts and also investigated the action on glucose. Since then Mohr, Bodecker, Violette, and others have varied the form and proportions of the alkali and tartrate used. But in view of the fact that the essential principles of this method were discovered by Barreswill, and indeed the method as used today is practically the one proposed by him, it is proposed that alk. Cu-tartrate solns., when used for detg. reducing sugars, be called "Barreswill's" soln. H. R. SMITH.

Determination of sucrose by double polarization employing a new method of clarification. NOEL DEER. *Intern. Sugar J.* 17, 179-82(1915).—The method of clarification is based on the pptn. of alumina within the soln. The reagents employed for both the direct and inversion readings are: (A) a satd. soln. of BaO and (B) a soln. of $Al_2(SO_4)_3 \cdot 10H_2O$ and H_2SO_4 made by dissolving 165 g. crystd. $Al_2(SO_4)_3 \cdot 10H_2O$ in water, adding 135 cc. $N H_2SO_4$ and making up to 1000 cc. A is titrated against B and B is dild. so that 25 cc. of A are equiv. to 15 cc. of B. For the *direct reading* 50 cc. of the material to be analyzed are placed in a 100 cc. flask, 25 cc. of soln. A are added and, after mixing, 15 cc. of soln. B are run in with agitation during the addition. The vol. is then completed to 100 cc. with the addition of 0.1 g. of Na hydrosulfite if needed for decolorizing effect. The filtrate is used to obtain the direct reading, which is increased by 0.7% to compensate for the vol. of the ppt. formed; or the vol. may be completed to 100.7 cc. or 49.65 cc. of the soln. may be taken. For the *inversion reading* 50 cc. of the material to be analyzed are placed in a 100 cc. flask, 15 cc. of soln. B are added, the flask placed in a water bath and the temp. maintained at 95 to 97° for 20 min. After cooling, 25 cc. of soln. A are added, and the inversion reading obtained exactly as for the direct reading. The sucrose is calcd. by the usual formula: $S = (D - I)/(C - (t/2))$. **Procedure for analysing molasses:** Dissolve 3.25 g. of molasses in 50 cc. of water and add 15 cc. of soln. B followed by 25 cc. of soln. A and about 0.1 g. of Na hydrosulfite. Complete the vol. to the mark, and filter, ascertaining the direct reading of the filtrate, and make the inversion, Na hydrosulfite being added after the addition of the BaO, and before filtration. With dark-colored molasses it is only possible to observe dil. solns., and with such Na hydrosulfite was found to have a considerable decolorizing effect. It was much easier to read an $1/8$ normal soln. of molasses in a 400 mm. tube than a $1/4$ normal soln. in a 200 mm. tube. The advantages claimed are that the direct and inversion readings are made under identical conditions; that the disturbing influence of Pb salts is eliminated; that it is particularly suited to analyses where sepn. of dextrose and levulose are required; and that a clarification is

obtained giving a filtrate well adapted for reducing sugar detns. and one without influence on the reducing sugars themselves. The results of a careful exam. of the method are given.

A. GROSS.

The deterioration of raw sugar samples. C. A. BROWNE. *Louisiana Planter* 54, 281-2(1915).—B. gives some data to clear up a current misunderstanding of the report of the New York Sugar Trade Lab. for 1914. The results in that report were based on expts. made with sugars kept in sealed glass jars and it should not be assumed that the same changes would occur in sugars stored in bags in a warehouse. In judging resistance of sugar, uniformity of character becomes a guiding principle. Moisture is not the only factor to be considered in the keeping quality of sugar. Expts. showed that the formation of invert sugar and other decomp. products during deterioration increase the percentage of non-sucrose ingredients to more than twice the moisture and so reach a point where deterioration automatically ceases. If the moisture content of raw cane sugars does not exceed $\frac{1}{3}$ of the non-sucrose solids, such sugars may be regarded as perfectly safe for dry storage. Tables of analyses of sugars are given to show the changes after different periods of time and under different storage conditions.

A. GROSS.

Varying concentration of the juice in the cells of the cane stalk. R. S. NORRIS. *Intern. Sugar J.* 17, 127-8(1915).—N. found that the juice extd. with a press from different parts of the cane increased considerably in density with each succeeding pressing. The explanation offered is that in the process of shredding, the cells with high density juice were ruptured along with the other cells, so that in pressing after shredding no increase in density of the juice was found at higher pressures. This would indicate that there is an advantage in the practical milling of cane in reducing it to a fine state of division, either by shredding or by the grinding action of the rollers in the early part of the process, so that none of this high density juice will be retained in the final bagasse.

A. GROSS.

Inversion in cut sugar cane. J. A. HALL, JR. *Louisiana Planter* 54, 269-70 (1915); cf. *C. A.* 8, 2633.—H. confirmed by expt. a previous suggestion that the inversion is due to enzymes and not to bacteria.

A. GROSS.

Use of hydrosulfites in manufacture of beet sugar. P. MARCUS. *J. fabr. suc.* 54, No. 47, 1; *Bull. Agr. Intelligence* 5, 130(1914).—A detailed account of the methods of application and the advantages realized by the use of hydrosulfites in the clarification of beet juice as practiced at the factory of Port-Salut-Verberie. 0.08 g. ZnSO_4 is added to the raw juice at the beginning of clarification, and the usual carbonation follows. This sulfitation costs about \$0.02 per ton of beets and allows a saving of 30% on limestone and 32% on coke. There is also a material decrease in the scums, in the loss of sugar in the cake, in the water required for washing, and in the cost of filtering. These savings total \$0.13 for each ton of beets treated. Account should also be taken of the more rapid evapn. and of the complete suppression of incrustations, which involves an economy of fuel. The successful application of this process demands an unusually close chem. control in the entire factory.

H. R. SMITH.

Catalysis in the oxidation of alkali sulfites. E. SAILLARD. *Compt. rend.* 160, 318-20(1915).—During the treatment of sugar solns. with SO_2 for clarification, some of the alkali sulfites formed are oxidized to sulfates. This action is thought to be due to the catalytic properties of some of the salts and other solids present. An exhaustive investigation of this subject has revealed the following facts: The oxidation of alkali sulfites in soln. is retarded by the presence of sucrose, invert sugar, nonsugar solids in general, NH_4 oxalate, glycerol, alkalis free from carbonates, asparagine, glutamic acid, and K lactate. The rate of oxidation increases regularly with rising temp. In the

presence of an increasing % of sucrose the effect of rising temp. diminishes. The curve which represents the retarding action of sugar rises rapidly and approaches an asymptote at about 60% sugar. The oxidation is very difficult with molasses. Oxidation is accelerated by the presence of powdered Zn, Ni, or Al, oxides of Fe and Mn, CaCO_3 , refractory bricks, CaSO_3 , CaSO_4 , CaC_2O_4 , $\text{Ca}_3(\text{PO}_4)_2$, MgCO_3 and AlPO_4 . Combination of circumstances which permit the appearance of any of these substances should be avoided whenever possible.

H. R. SMITH.

The sucrose content of scums. H. PELLET. *Intern. Sugar J.* 17, 132-3(1915).

—The insol. sucrose in scums is not all in the form of Ca sucrate but is also in an insol. form pptd. by the addition of lime, but not as sucrate. When found in an appreciable quantity in the scums (0.30-0.40% or more), there is cause to exam. the milk of lime. The diminution of polarization on liming is attributed to the entrainment of sucrose in the insol. state by the very bulky ppt. formed on adding lime to the already dense diffusion juice. Methods are given for the detn. of the total insol. sucrose and for conducting a liming test of the raw juice.

A. GROSS.

The Norit process of manufacturing white sugar. A. WIJNBERG. *Intern. Sugar J.* 17, 129-31(1915).—Continuation of a previous article (cf. *C. A.* 9, 1132). W. reports trials made in Natal and Scotland, advantages for the refiner and the application of the process in the beet sugar factory.

A. GROSS.

Frothy fermentation in the after-products of cane sugar manufacture. H. C. PRINSEN-GHEERLIGS. *Louisiana Planter* 54, 205-6(1915).—This phenomenon is ascribed to the decomp. of derivs. of sugars and not necessarily to the primary decomp. of glucose under the influence of alkaline matter. It is also produced by overheating. G. suggests that the best way to prevent the frothy fermentation is first to avoid any heating of glucose containing juices or sirups with lime at temps. above 60°. Next the vacuum in the pans should be a high one in order to have the after-products formed boil at a temp. below 70°. All products should be made to grain as far as possible in order to prevent the masseccutes remaining too long in the hot rooms.

A. GROSS.

The rational imbibition (maceration) of bagasse in the cane sugar factory. L. PELLET. *Intern. Sugar J.* 17, 123-7, 175-8(1915).—Continuation of a previous article (*C. A.* 9, 1130). A detailed study was made of the different arrangements for imbibition that may be adopted in practice according to the type of milling installation, detn. of the total water added to the bagasse, the amt. of imbibition and its relation to evapn.

A. GROSS.

Practical control of the density of fullmass or masseccute. F. E. COOMBS. *Louisiana Planter* 54, 203-4(1915).—The method is based upon the fact that a small drop of fullmass, free from bubbles, will float upon any liquid of greater density than its own, and will sink into this liquid as soon as its density becomes equal to or greater than that of the liquid. Pb subacetate soln. was found to be the best suited for the purpose.

A. GROSS.

The fiber content and the fuel problem. W. E. CROSS. *Revista agricola de Tucuman; Louisiana Planter* 54, 266(1915).—Owing to the low fiber content of the cane milled in Louisiana, Tucuman, etc., the bagasse produced is not sufficient to provide all the fuel necessary to run the factory.

A. GROSS.

The use of sweet sorghum as a source of commercial sugar or as fodder. H. E. ANNETT. *Agr. Res. Inst. Bull. (Pusa)* 41, 9 pp.(1914); *Bull. Agr. Intelligence* 5, 1596-7(1914).—A. describes a series of expts. made at Lyallpur and Gurdaspur, Punjab. As a source of sugar, saccharin jowar (sorghum) is not worth growing in India (no demand for the sirup). The high glucose ratio of the juice militates against the pro-

duction of good cryst. jaggery. The juice contains also substances which produce, at times, a very objectionable taste in the jaggery. Yield per acre = about 8 cwt. The total sugar content of the crop was highest when the seed contents began to dry. Thereafter until the seeds are dead ripe the total sugar decreases, mainly at the expense of the reducing sugar. As the plant approaches ripeness the amt. of juice expressed from it decreases. As a source of fodder this sorghum seems valuable.

F. W. SMITHER.

Tacca umbrarum. ANON. *J. agr. tropicale; Giorn. farm. chim.* 63, 116(1914).—The tubers of this plant (which is indigenous to Madagascar) give a yield of approx. 30% dry starch when treated by com. processes, as compared with a yield of 20-2% obtained from manioc. The native method of extg. starch from these tubers consists in a crude mechanical sepn. followed by washing (in order to remove toxic and bitter principles) and sun drying.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

A study of some recent methods for the determination of total sulfur in rubber. J. B. TUTTLE AND A. ISAACS. Bur. of Standards, *Tech. Paper* 45, 16 pp.; *J. Wash. Acad.* 5, 235-6(1915); *J. Ind. Eng. Chem.* 7, No. 7(1915).—The investigation was undertaken to learn whether or not the methods recently published for the detn. of total S in rubber are any improvement over the method of Waters and Tuttle (*C. A.* 6, 1107). The methods investigated were those of Spence and Young (*C. A.* 6, 2545), of Deussen (*C. A.* 8, 261), of the Joint Rubber Insulation Committee (*C. A.* 8, 1214), of Alexander (*Gummi-Ztg.* 18, 729-30(1904)), of Kaye and Sharp (*C. A.* 7, 1107), of Frank and Marckwald (*Gummi-Ztg.* 17, 71(1903)), and of Waters and Tuttle. These were subdivided, according to the method of attack, into 3 classes: direct soln., direct fusion, and soln. and fusion methods. A large number of detns. were made on a number of samples, 2 of the latter being of known comp. (specially prepared). The methods may be divided into 2 classes, *vis.*, those for the detn. of total S and those for the detn. of S other than that present in the insol. sulfates. It was found that the second class could not be relied upon to give accurate results. The use of conc. HNO_3 , as in the methods of Spence and Young, and of Deussen, causes low results. The direct fusion methods of Alexander, of Kaye and Sharp, and of the Joint Rubber Insulation Comm. are reliable only when the free S content is low and are therefore not applicable to routine analysis. The soln. and fusion method of Frank and Marckwald was found to be unreliable when the free S was high. The Waters and Tuttle method was found to be satisfactory, and is recommended for general use. A new suggestion is offered, *namely*: to det. separately the free S, and the S remaining after the extn., reporting the sum of the two as total S. This eliminates the troublesome effect of the free S on the detn. of total S.

CHEMICAL ABSTRACTS

Vol. 9.

JULY 10, 1915.

No. 13.

I. APPARATUS.

L. C. JONES.

New type of apparatus for the reduction of iron solutions by metallic aluminium. C. L. SCHUMANN. *J. Ind. Eng. Chem.* 7, 431(1915).—An Al chain attached to a glass rod is used instead of an Al spiral. ISADOR MILLER.

Collodion diffusion cell for use in dialysis. T. R. BRIGGS. *Cornell. J. Phys. Chem.* 19, 377-80(1915).—It is difficult to prepare collodion membranes for dialysis by Novy's method (cf. Bigelow and Gemberling, *C. A.* 2, 618). Substitute cells may be prepd. very easily as follows: A large Soxhlet extn. cartridge is filled with collodion soln. (Kahlbaum's Ph. G. V.) and emptied as soon as the pores of the paper are completely impregnated. As soon as the collodion has set the process is repeated. Three coats are applied. The collodion cannot be allowed to dry in air as it becomes practically impervious to H_2O , but the cell is partially dried in a current of air, *i. e.*, until the ether is removed (about 10 min.). It is then put into H_2O , which displaces the alc., leaving the cell ready for use. If 6% glycerol (the amt. is established by comparative tests using different percentages) is added to the collodion before the cell is prepd. it may be completely dried in air and kept for a long time before using. Comparative tests, using NaCl, show this new form of diffusion cell to be more efficient than the ordinary type of parchment thimble but less efficient than collodion sacs prepd. by Novy's method. F. A. HARVEY.

Sand blast for marking glassware. G. SPITZER AND L. S. TRACHSEL. *J. Ind. Eng. Chem.* 7, 426-7(1915).—The app. is described with drawings. I. M.

Two more new specific gravity balances. M. V. SCHWARZ. *Centr. Min. Geol.* 1915, 97-106; *Chem. Zentr.* 1915, I, 517.—A model adapted for the purpose of instruction and demonstration is developed from the type previously described (*C. A.* 5, 1212) in which the scale is divided into 0.1 g., and with which it is best to use fragments weighing 10-20 g. Then for the smallest fragments, 0.01-0.02 g., a torsion balance with and without a reading mirror is shown and the method of using it described. Tables are given showing the value and size of the scale parts with the torsion balance and the exptl. results of d. detns. for the purpose of instruction, as well as with the precision balance. With some practice, the length of time required for a weighing with the last named balance (made by Hartmann & Braun, Frankfurt) is 5-10 sec. J. H. BOWER.

An aneroid calorimeter. H. C. DICKINSON AND N. S. OSBORNE. *J. Wash. Acad. S.* 337-8(1915).—(In full later as *Sci. Paper* 247, Bur. Standards). The term "aneroid calorimeter" is applied to a type of calorimeter in which equalization of temp. is secured by means of the thermal cond. of Cu instead of by the convection of a stirred liquid. The instrument consists of a thick-walled cylindrical Cu vessel, in the walls of which is embedded a coil of resistance wire to supply heat electrically, and of a Pt resistance coil for use as a thermometer. It has been found useful over a wide range of temps. and is applicable to a variety of problems. For use at low temps. the calorimeter is mounted in a jacket surrounded by a bath of gasoline, the temp. of which can be controlled thermostatically to within a few thousandths of a degree at any temp.

between -55° and $+40^{\circ}$, or it can be changed rapidly in order to keep it the same as that of the calorimeter when heat is being supplied to the latter. Differences in temp. between the surface of the calorimeter and that of the jacket are measured by means of multiple thermocouples which have 10 junctions distributed over the surface of each, thus making it possible to apply accurate corrections for thermal leakage between calorimeter and jacket even when the temps. of both are changing rapidly. The Pt resistance coil shows slight irregularities in its behavior, probably due to the difference in expansion between the Pt and the Cu which surrounds it. These uncertainties, while negligible, can be avoided by measuring the temp. of the outer bath with a standard resistance thermometer, using the thermocouples to measure the small difference, usually not more than a few thousandths of a degree, between the calorimeter and the jacket. Results of a series of expts. give the consts. of the resistance thermometer and the heat capacity of the calorimeter including a Sn-lined cell for use in detg. the sp. heat of ice and H_2O and the latent heat of fusion of ice. A series of check expts. on the sp. heat of H_2O show the order of reproducibility of results to be 1 part in 2000. Measurements made at temps. between 0° and 40° gave results which agree to within the limits of exptl. accuracy with the results of a series of expts. made in the usual form of stirred H_2O calorimeter. The results are also in satisfactory agreement with the most probable values deducible from the data of the most careful investigations published by other observers.

F. W. SMITHER.

Gas-fired industrial furnaces. ANON. *Engineering* 99, 460-2(1915). A description with drawings of a pressure-gas-fired annealing furnace, a natural draft gas-fired annealing furnace and a crucible furnace.

W. L. BADGER.

The "Bracq-Moritz furnace" for roasting pyrites and similar material. SEIG-FRIED BARTH. Düsseldorf. *Chem. App.* 2, 95-6, 105-7(1915).—A description, with 11 cuts, of this oven. It is simple in construction and operation and is said to give excellent results with regard to the solubility of the Cu in the roasted ores. J. H. M.

High-efficiency chimney-cooler with stepped-grate air-entrance. ANON. *Chem. App.* 2, 104-5(1915).—A cut and description of the Maschinenbau-Aktienges. Balcke, Bochum. water cooler, with 2 cuts of older forms for comparison. J. H. MOORE.

Grinding and crushing machinery. M. A. CROSBY. *J. Soc. Chem. Ind.* 34, 320-7(1915).—A discussion of types and principles.

W. L. BADGER.

A thermoregulator with water temperature control. L. v. HAYDENREICH. *Centr. Bakt. Parasitenk., Abt. I*, 73, 444-8(1914).—An app. is described which is designed to be used when gas and electricity are not available. The source of heat is an oil lamp.

J. H. LEWIS.

Recent progress in pyrometry. C. R. DARLING. *J. Roy. Soc. Arts* 63, 590-607 (1915); *Gas World* 62, 571-2(1915); *Engineering* 99, 564-5(1915); *J. Gas Lighting* 130, 457-8(1915).—The past few years have witnessed a great extension of the use of base metals in the construction of thermal junctions. Properly chosen base metal couples develop a relatively high e. m. f. and therefore make possible the use of a strong and cheap indicator in place of the sensitive instrument required for couples of the Pt series. New types of optical pyrometers have come into use, based on the principle of color extinction. Modern tendency is in favor of continuous inked records. Cf. *C. A.* 8, 2086.

M. L. TROWBRIDGE.

Recent advances in electrical pyrometry. R. W. PAUL. *Pat. Gas.* 39, 1278-81(1915).—It is pointed out that a thermo-couple circuit of high resistance, composed of wire of negligible temp. coeff., is necessary for a reasonable degree of accuracy of measurement of temp. Pt-Rh couples are more permanent than Pt-Ir, but produce a lower e. m. f.

Cyclical evolution of the chemical elements. II. **F. H. LORING.** *Chem. News* 111, 181-2(1915); cf. C. A. 9, 1413.—The speculations are resumed. Following L.'s idea that the elements are made up of mixts. of other "elements" with at. wts. which are whole numbers, Ne is imagined (on somewhat insecure ground) to be a mixt. of 10 ats. with at. wt. of 20 and one with an at. wt. of 22. This would be a mean at. wt. of 20.18, which is close to the accepted value. Cl is again assumed to be composite, contg. 10 ats. of wt. 35 and 1 with at. wt. of 40. **E. B. MILLARD.**

Reactions between two gases. **M. TRAUTZ.** Heidelberg. *Z. Elektrochem.* 21, 118-22(1915).—Theoretical. The mass action equation $k = \kappa \sqrt{T} \pi^{\pi} (c/e^{\pi})(1/e^{\pi})$

has been derived as a general case. (Details of the derivation are not given.) Here the power κ has the value $q_0/RT + \int_0^T dT/RT^2 \int_0^T c_p dT$; κ is a universal const. $10^{35} \pm 1$ for all reactions in which the course of the reaction is known, and is independent of wall-effects, etc. The Σq_0 for all such reactions is the sum of the heats of activation, and is const. for the reactions considered for all temps. (Cf. *Sitzb. Heid. Akad. Wiss.* (A) 1914, No. 1.)

E. B. MILLARD.

Potassium chloride concentration cells. D. A. MACINNES AND KARR PARKER. *J. Am. Chem. Soc.* 37, 1445-61 (1915).—Concn. cells of the type $\text{Ag} | \text{AgCl}, \text{KCl}(C_1) | \text{K}(\text{Hg})_x - \text{K}(\text{Hg})_x | \text{KCl}(C_2), \text{AgCl} | \text{Ag}$ have been measured at 25° , and the e. m. f. compared with cells in which transference took place. These cells were $\text{Ag} | \text{AgCl}, \text{KCl}(C_1) | \text{KCl}(C_2), \text{AgCl} | \text{Ag}$. With the same soln. in cells of both types, transference numbers were detd. as 0.498 from 0.5-0.05 *N*, 0.496 from 0.1-0.01 *N*, and 0.494 from 0.05-0.005 *N*; the Hittorf numbers for this range are 0.496, 0.496, 0.496. The measurements indicate that the "activities" of the ions from KCl are much lower than their concns. as calcd. from conductance measurements, but the activity approaches the same limit as the concn. at great dilns.

Effect of light on chlorine water. A. BENRATH. *Z. wiss. Phot.* 14, 238 (1915).—A reply to Dawson's criticism (cf. *C. A.* 9, 748), denying its validity.

L. DERR.

Diffusion of carbon dioxide through rubber. V. RODT. *Chem. Ztg.* 38, 1249-51 (1914).—R. concludes that the diffusibility of gases through rubber depends upon the moisture content and the solubility of the gases in H_2O . The numerical values found in the literature for the diffusibility of gases through rubber vary, and R. considers them uncertain because the moisture content of the rubber was not considered.

EDWARD J. KELLEY.

Reciprocal solubility of liquids which are not miscible with water. W. HERZ. *Boll. chim. farm.* 54, 37 (1915).—The following figures represent the number of vols. of the substances indicated which are required to sat. 100 vols. of the solvent at 22° : CHCl_3 in H_2O , 0.420; H_2O in CHCl_3 , 0.152; CS_2 in H_2O , 0.174; H_2O in CS_2 , 0.961; ligroin in H_2O , 0.341; H_2O in ligroin, 0.335; Et_2O in H_2O , 8.110; H_2O in Et_2O , 0.930; benzene in H_2O , 0.082; H_2O in benzene, 0.211; amyl alc. in H_2O , 3.284; H_2O in amyl alc., 2.214; PhNH_2 in H_2O , 3.481; H_2O in PhNH_2 , 5.220.

H. S. PAINE.

Growing crystals for measurement. J. M. BLAKE. *Am. J. Sci.* 39, 567-70 (1915).—Attention is directed to the necessity of a carefully controlled temp. and slow rate of growth if large perfect crystals are to be formed. Some crystals may be grown from suspended smaller ones. Weeding out imperfect crystals was also mentioned.

E. B. MILLARD.

Method of reducing some metals in crystallized form on glass slips as permanent microscopic mounts. J. H. BOWMAN. London, Ont. *J. Am. Chem. Soc.* 37, 1468-71 (1915).—A 10% soln. of AgNO_3 was mixed with a concd. soln. of $\text{Zn}(\text{NO}_3)_2$ to prevent drying, and spread upon a slip. Fine Zn dust was then sprinkled over the soln. by filing a Zn rod over it, and crystals of the Ag commenced to form on the Zn particles. Satisfactory crystals of Ag, Au, Cu, Pb, Bi, and Cd were obtained by this method. Photomicrographs showing the crystals are given.

E. B. MILLARD.

Photochemical sensitiveness and photochemical conductivity. M. VOLMER. Leipzig. *Z. Elektrochem.* 21, 113-7 (1915); cf. *C. A.* 7, 1136, 3901; 8, 613.—Using the app. of Pauli (*C. A.* 7, 3900) the photoelec. effect has been measured for AgCl , AgBr , AgI , S, Se, P (yellow), Sb_2S_3 , Cl, Br, HgCl_2 , HgI_2 and several organic compds. There must exist a connection between photochem. sensitiveness and cond. The primary mol. change which is responsible for the cond. must be independent of the

state of aggregation of the substance. Anthracene (*c. g.*) shows the same resonance electrons whether in the solid, dissolved or gaseous state. Several theories are discussed, but no definite conclusion is reached.

J. H. MOORE.

Physicochemical kinetics. R. MARCELIN. *Ann. phys.* 3, 120-84(1915).—An extended mathematical discussion of kinetics. Formulas are derived for transformations at const. temp. An attempt was made to derive the expression for the speed of a reaction from the distribution law, and equations showing the influence of temp. on the speed of a reaction were given. Several applications were given, first the general case, then the sublimation of I, of $C_{10}H_8$, and the evapn. of $C_6H_5NO_2$. The mathematical treatment must be obtained from the original.

E. B. MILLARD.

Atoms and ions. J. J. THOMSON. *Engineering* 99, 413-5(1915); cf. *C. A.* 9, 1560.—Concluding lecture. The carriers of electricity in a gas could be charges or larger systems, and perhaps only the latter have sufficient energy to ionize the other mols. with which they collided. This was tested by expt., and it was shown that either the negative charges or the positive particles could split the mols. into ions. When a Ra salt was dissolved in H_2O , the gases given off contained less O than they should, and it was found that the O from the negative particles had gone to oxidize the H_2O , and peroxides were in soln.

E. B. MILLARD.

Mobilities of ions in air. E. M. WELLISCH. *Yale Univ. Am. J. Sci.* 39, 583-99 (1915).—Expts. have been made on the velocities of positive and negative ions in air under a variety of exptl. conditions. From 1 atm. to 0.05 mm. the mobility of the positive ion varied inversely as the pressure, showing that the nature of this ion remained essentially unchanged over this wide range of pressure. The negative carriers were of 2 kinds, electrons and ions, the former increasing in number relative to the latter as the pressure was diminished. Each kind possessed its characteristic velocity in an elec. field, and there was no evidence of the formation of any intermediate stage. Electrons appeared in measureable amts. at pressures below 80 mm. The negative ion remained unaltered over a range of pressure from 1 atm. to 0.15 mm. The view was expressed that all previous expts. on the velocity of ions at low pressures are based on the untenable assumption of the presence of an "average" ion and are thereby invalidated.

E. B. MILLARD.

Osmotic compressibility of emulsions and the influence of adjacent surfaces upon Brownian movements. R. COSTANTIN. *Ann. phys.* 3, 101-20(1915); cf. *C. A.* 8, 2514.—Two sets of expts., one on distribution with height and the other on av. condensation, showed that the law of van der Waals could be applied to concd. emulsions. There was evidence of the existence of a negative interior pressure, a repulsion between the grains of the emulsion which acted at distances of the order of their radii. The verification of the formula of van der Waals and the general theory of Smoluchowski shows that colloids have all the properties of fluids required by the kinetic theory. A value of Avogadro's N of 64.5×10^{23} was found.

E. B. MILLARD.

Osmotic pressure and concentration in solutions of electrolytes, and the calculation of the degree of dissociation. STUART J. BATES. *J. Am. Chem. Soc.* 37, 1421-45 (1915).—Assuming that the 2 ions of a di-ionic electrolyte behave similarly, and that the degree of dissociation can be calcd. from conductance and viscosity data, methods were developed and applied for computing the osmotic pressure of the ions of a salt. The osmotic pressure of an ion was in general a few % less than that calcd. from van't Hoff's law; that of an undissociated mol. was considerably greater; even at 0.0001 N the deviation was about 15%. The bivalent ions deviate from van't Hoff's law more

than the univalent ones. On the other hand, the undissociated mols. of the bi-bivalent salts obey that law rather closely. At concs. up to about 0.05 *N* the various univalent ions behave practically the same as regards their osmotic pressure-conc. relations; the same applies to the bivalent ions. The relation between osmotic pressure and concn. for both univalent and bivalent ions may be expressed by an equation of the form $d\pi/dC_i = RT(1 + bC_i^m)$. In dil. solns. a similar equation represents the undissociated mols. For KCl between 0.001 and 0.5 *N* the total pressure calcd. from such relations agreed with the exptl. values to within 0.10% on the average. Calcn. of the degree of dissoc. from f. p. data by the aid of the mol. number *i* assumes that both the ions and undissociated mols. are "normal," and hence is theoretically incorrect.

E. B. MILLARD.

The thermionic current. A. S. EYE. MCGILL UNIV. *Nature* 95, 174(1915).—A simple method is suggested for exptg. with the thermionic current; the equipment consists of a filament lamp silvered inside; a Pt wire which passes through the side of the glass and makes elec. connection with the belt of Ag, is connected to one terminal of a telephone receiver, the other terminal being connected to the water mains. With an a. c. at 110 v., a loud note is heard depending on the frequency of alternation. With a d. c. from a dynamo, there is sufficient variation in the voltage to obtain a sound just audible at 100, loud at 110, very loud at 130, and still louder at 140. Above 142 v. there is silence. In explanation of this result it is pointed out that the thermionic current does not increase with the temp. according to Richardson's law unless the vacuum is of a high order (Langmuir, *C. A.* 8, 1230). With a moderate vacuum the vol. charge between the filament and Ag causes the thermionic current to remain at a value nearly const. as the temp. is raised above a certain value. The thermionic current begins by obeying Richardson's law and then later approximates to a steady value. Thus at low voltages variations of voltage cause variations of temp. and consequent fluctuations of thermionic current heard through the telephone. Above 140 v., for the particular lamp used, a change of voltage and of temp. produces no change of current, and hence no sound can be heard in the phone.

Unique geophysical phenomenon, Trinidad asphalt, interesting from the point of view of dispersoid chemistry. CLIFFORD RICHARDSON. *J. Phys. Chem.* 19, 241-9 (1915).—A description of this asphalt from the point of view of dispersoid chemistry.

E. B. MILLARD.

Tyndall phenomenon. E. WILKE. Heidelberg. *Z. Elektrochem.* 21, 117-8 (1915).—By means of a polarization photometer (to be described later) it was shown that the intensity of light from a Tyndall cone changed with increasing thickness of the film of colloid according to an exponential law $I = I_0 \int_0^x e^{(\omega - x)} dx = (I_0 / \omega)(1 - e^{(\omega - x)})$, where *x* was the thickness of the film. Further, ω had an abnormally high value, about 200 times the value of β of the normal exponent of absorption. It was found that ω depended somewhat on the intensity of the light, and both ω and I_0 were governed by specific properties which characterized the colloid. The abnormal light weakening was found only when the wave length of the light radiated was the same as that of the original light source. There was a similarity between the light from the colloid and that radiated from a glowing body. The work will be continued.

E. B. M.

Thermal effect of solution. M. LEVAL-T-EZERSKII. *J. Russ. Phys. Chem. Soc.* 47, 177-85(1915).—The simple assumption that when soln. is accompanied by a contraction of vol. there is evolution of heat, while with dilatation of vol. there is absorption

of heat, is not borne out by expts. A correct relation between vol. changes and thermal effect of soln. is to be found by comparing the heat effect with the changes in vol. which take place when the soln. is made at different temps. Regarding dilatation as negative contraction, one has the following equation: $k = 1 - V/(v_1 + v_2)$, where k is contraction, V = vol. of soln., v_1 = vol. of solvent, and v_2 = vol. of solute. By comparing the values of k for solns. made at 2 different temps., it was found that in all the cases examd. there is evolution of heat when k increases with an increase of temp., and absorption of heat when k is smaller at the higher temp. This was corroborated by expts. with $MgCl_2 \cdot 6H_2O$, H_2SO_4 , K_2SO_4 , NH_4Cl , $CaCl_2 \cdot 6H_2O$, $Pb(NO_3)_2$, $NaNO_3$ and $ZnSO_4 \cdot 7H_2O$. The 1st 2 dissolve with evolution of heat, and the contraction of vol. (in some cases positive, in others negative) increases with the temp., while the other 6 compds. dissolve with absorption of heat, and k is smaller at the higher temp. For numerous other substances the above relation could not be verified, owing to a lack of data in the literature. For these another relation was established. On comparing the values of k at 2 different concns., but at the same temp., one gets, by subtracting the k for the greater from the k for the smaller diln., the value of k_1 , due to diln. at that temp. A similar comparison made at a higher temp., using the same initial and final concns., gives the value of k_2 , due to diln. at the higher temp. It was found that when for a given substance k_2 is greater than k_1 , that substance dissolves in H_2O with evolution of heat, and *vice versa*. This rule seems to hold good for substances which do not participate in the formation of vapor above the soln. Further work is promised.

H. M. GORDIN.

Viscosity of liquid mixtures. II. A. N. SAKHANOV AND N. A. RYAKHOVSKIY. *J. Russ. Phys. Chem. Soc.* 47, 113-33(1915); cf. *C. A.* 8, 1532.—Further expts. with numerous org. substances gave the following results: The viscosity η of a mixture of 2 non-interacting liquids having the viscosities η_1 and η_2 , resp., is given by the equation: $\eta = H - kx(1 - x)$, where x and $1 - x$ are the molar concns. of the components, $H = \eta_1(1 - x) + \eta_2x$, and k = const. The greater the difference between η_1 and η_2 the greater is k , i. e., the greater is the digression from the law of additivity. When the components do not interact chemically k is always positive. When there is interaction, e. g., ketones or ethers with the halogen derivs. of hydrocarbons, the viscosity curve is above that of non-interacting liquids. The character of the curve when there is interaction depends both on the intensity of the latter and the ratio $\eta_1 : \eta_2$. The varieties of curves are: the curve of Kurnakov and Zhemtchuzhnyi (*C. A.* 7, 1126), curves with max., convex curves, concave curves and straight lines. Many of the systems in which there is interaction also obey the above equation. This happens when the compd. produced is of simple compn., consisting of 1 mol. each of the components. Only halogen derivs. of the $CHCl_3$ type, i. e., such as are poor in H, ($CHCl_3$, $C_2H_2Cl_4$, C_2HCl_3) are capable of interacting with ketones or ethers.

Calculation of the column correction for standardized thermometers. H. SCHLÜTER. Kgl. Materialprüfungsamt, Berlin. *Chem. Ztg.* 39, 177-8, 197-8, 202-4 (1915).—Descriptions of various methods with formulas for calcg. the corrections.

J. H. MOORE.

Characteristics of radiation pyrometers. GEORGE K. BURGESS AND PAUL D. FOOTE. *J. Wash. Acad.* 5, 233-4(1915).—(In full later as Sci. Paper, Bur. Standards.) The complete paper (about 100 pp., 32 figs.) contains an account of the principles which form the basis for the operation of total radiation pyrometers, descriptions of the various types of the instrument, and results of an exptl. study of their calibration and behavior under various conditions of use. The thermoelec. radiation pyrometer

follows the law $\epsilon = aT^b$ where ϵ is the e. m. f., T the abs. temp., and a and b are consts., b having a value ranging from 3.5 to 4.5. The somewhat selective absorption of the receiver is not of serious importance below 2500°. Galvanometers and auxiliary app., recorders, etc., as constructed at present, are not in general a source of serious error. The main errors lie indirectly in the receiving system and consist of stray reflection, convection currents, improper geometrical construction, dirt on mirrors, lag, focusing distance and size of source. With care temp. may be measured with accuracy of 5 to 10°, but the instruments as ordinarily used are likely to be in error by 50 to 100°. Methods of calibration (two primary and one secondary) are given. Proper methods of use of the instruments for both tech. and lab. practice are discussed. The detn. of total emissivity and the measurement of the temp. of nonblack materials are treated. Correction tables are given for use with molten Fe and Cu, oxides of Cu, Fe, and Ni, and Pt.

PAUL D. FOOTG.

Drop weight method for determining the surface tension of a liquid. J. L. R. MORGAN. *J. Am. Chem. Soc.* 37, 1461-7(1915); cf. *C. A.* 7, 3604, 3879; 8, 1041-2. —An outline of the exptl. conditions which must be fulfilled if the law of Tate is to hold. The tip must have a diam. of 4.5 to 5.5 mm., and the vol. of the drops from these tips must be at least 0.0196 and 0.0239 cc., resp. The actual tip diams. are not necessary for the calibration of the tip and are not used in it. The criticism of Lohnstein (*C. A.* 8, 1041) was unjustified. Drop weight and surface tension as found by the capillary rise method are proportional.

E. B. MILLARD.

Double bands in the residual rays of diatomic substances. W. C. MANDERSLOOT. Utrecht. *Physik. Z.* 16, 36-7(1915); cf. Rubens and Wartenburg, *C. A.* 8, 2302. —There is a close similarity between the double bands in the visible range bordering the ultra-red for gases and those of the residual rays of solid substances. This is explained by the linear vibrations of the electrically charged atoms perpendicular to the axis of rotation. Distances between atoms (l) calc. from the double bands of residual rays of diatomic solid substances and those calc. for gases with double bands are of the same order of magnitude. *E. g.*, the values of l obtained for CO, HCl and HBr, resp., are 1.14, 1.34 and 1.49×10^{-8} cm.; those for NaCl, KCl, KBr and AgCl, resp., are 1.67, 2.08, 1.31 and 1.46×10^{-8} cm.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

Practical methods for the determination of radium. I. Interchangeable electro-scope and its use. S. C. LIND. *Bur. Mines. J. Ind. Eng. Chem.* 7, 406-10(1915).—L. describes a new electroscope of very simple construction and made in 2 detachable parts, the upper the telescope and leaf system, and the lower the discharge chamber. The former can be used on any number of sep. lower parts. The method of procedure in making detns. by the emanation method is described. ISADOR MILLER.

Radioactive springs. H. VON HÖFFER. *Vienna. Intern. Z. Wasser-versorg.* 1, 52-5, 90-3(1914).—Data obtained by the several investigators, who use the Engler and Sieveking fontactoscope, show (1) that cold springs are more active than hot springs; (2) that waters high in salts are very low in activity; (3) that the presence of active or inactive minerals in the earth's strata influences the activity; and (4) that deep wells are more active than shallow wells. The results are only qualitative. C. S.

The intensity of X-ray spectra. DAVID L. WEBSTER. *Harvard Univ. Physic. Rev.* [2] 5, 238-43(1915).—A mathematical paper showing that the presence of the factor $\sin^2 \theta$ in Bragg's equation for the intensity of the reflection of homogeneous X-rays from a crystal indicates that the train of waves emitted by an atom in the radiator is short compared to the distance the rays travel through the crystal. G. L. WENDT.

Some secondary effects from Röntgen rays. PAUL T. WEEKS. *Cornell Univ. Physic. Rev.* [2] 5, 244-8(1915).—Gorton's anomalous observations (*C. A.* 8, 1700) are attributed to a general scattered radiation. It is necessary to screen a sensitive plate from all sides when in the vicinity of an active X-ray tube. A metal backing on the plate improves the contrasts by eliminating the scattered rays, but introduces secondary rays from the metal itself. The emission of secondary rays varies widely among different metals with the penetration of the primary rays. G. L. WENDT.

The extraction and purification of radium emanation. WILLIAM DUANE. *Harvard Univ. Physic. Rev.* [2] 5, 311-14(1915).—A description is given of a method for collecting daily accumulations of Ra Em, the app. for which consists of a small glass bulb containing a Ra salt in water soln. and connected to a large glass reservoir through a U-tube which functions as a stopcock when Hg is introduced from below. The Ra Em collects in the evacuated bulb and reservoir. Raising the Hg closes the bulb and forces the Ra Em from the reservoir into a system of purifying tubes. A partially

oxidized Cu wire coil is heated to redness electrically and serves to recombine the H and O formed from the water of the Ra soln.; about 0.13 cc. per millicurie of Ra Em are formed. P_2O_5 removes water and KOH the CO_2 . By means of another exhaustible reservoir, and U-tube connection, the purified Ra Em can now be drawn from the tube system and forced into any desired vessel. All contact with stopcock grease is avoided. The advantages of the method are: that the purification does not require liquid air; that a large number of millicuries of Em can be purified and compressed into a small fraction of a cu. mm., in 10 or 15 min. of time; that no Em is lost except that due to its natural decay; and that the process may be repeated a great many times without removing parts of the app. G. L. WENDT.

The absorption of homogeneous Röntgen rays. II. W. KOSSEL. *Verh. deut. physik. Ges.* 16, 953-63(1914).—On the basis of Bohr's atom model (C. A. 7, 3712; 8, 461), K. accounts for the appearance of fluorescence and the increase of absorption of X-rays at a frequency close to that of the second strongest line of the emission spectrum. The absorbed radiation is assumed to remove an electron from the innermost K-ring of the atom. Its replacement by an electron from the second ring is accompanied by an emission of energy which corresponds to the K- α line in the spectrum. This is itself replaced from the third ring, giving the L- α line, and the series is thus continued in the direction of longer wave-lengths until the outer valence-ring and visible light waves are attained. When replacement occurs from the third ring directly to the first, the emission corresponds to the K- β line, the frequency of which is expressed, both theoretically and practically, by $\nu_{K\beta} = \nu_{K\alpha} + \nu_{L\alpha}$; similarly, $\nu_{K\gamma} = \nu_{K\alpha} + \nu_{L\beta}$, etc. G. L. WENDT.

Ion clouds in moist expanded air. G. QUINCKE. Heidelberg. *Ann. Physik* 46, 39-67(1915); *Verh. deut. physik. Ges.* 16, 421-3(1914).—Detailed study of the plates of C. T. R. Wilson (C. A. 7, 932) shows, by analogy with Q.'s photographs of the "vegetation" of salts pptd. from soln., that the clouds formed by the expansion of ionized air have a foam structure, each bubble or chamber containing one or more ions in the form of an "oily" soln. Differences in the foam structure are due to surface tension differences with ions from different sources. The clouds are not composed of droplets; they do not fall vertically, nor with a constant velocity. This invalidates all detns. of the ionic charge by the cloud method. G. L. WENDT.

Polarization and index of absorption of Röntgen rays from platinum and carbon. H. KIRSCHBAUM. Aachen. *Ann. Physik* 46, 85-129(1915).—The intensity of X-radiation from a Pt anticathode is 17 times that from C at the same potential. The absorption-index measured photographically differs from that obtained with an ionization chamber because Ag and Br have a different selective absorption from N and O. The absorption in Al is greater for C radiation than for Pt in the ratio 100 to 77. Absorption varies rapidly with the tension between 12000 and 15000 v., but at higher voltages is stable. The azimuth varies slightly with the voltage below 25000 v.; but at 28000 v. it is about 66°. G. L. WENDT.

X-Ray photographs of the diamond. ERNST KELLER. Munich. *Ann. Physik* 46, 157-75(1915).—Analysis of Laue's, Friedrich's and Bragg's crystal photographs, confirms both Bragg's structure for the diamond (C. A. 8, 599) and Laue's theory that a crystal reflects from the continuous spectrum impinging upon it only the wave-lengths capable of passing between its lattice structure. The abnormally wide dispersion given by the diamond is due to its small lattice constants, its small absorption of the rays, and its wide deviation from the law of Dulong and Petit. G. L. WENDT.

A count of the electrons emitted from metal foils under weak Röntgen radiation. ERICH HOEPFNER. Univ. Greifswald. *Ann. Physik* 46, 577-604(1915).—The number

of electrons emitted by a Pt foil (as detd. by the collision-ionization method) per sq. cm. per sec. is $10 \times 10^{-10} i$, where i is the intensity of the X-radiation. This is $1/150$ of the value found by Carter (*Ann. Physik* 21, 995(1906)). The fact that electrons are emitted at once, without an induction period, is taken as proof that Sommerfeld's quantum theory (*C. A.* 6, 2029) is inapplicable, and that the energy of the electron is derived from the atom itself. The X-ray simply "calls forth" the already imminent explosion of the labile atom.

G. L. WENDT.

The production of Röntgen rays by slow cathode rays. ELIZABETH R. LAIRD. Univ. Würzburg. *Ann. Physik* 46, 605-22(1915); cf. Thomson, *C. A.* 9, 21.—By the use of a celluloid window the production of X-rays could be proved for primary potentials as low as 220 v. Below 450 v. the relation between the intensity of the X-radiation and the potential becomes irregular. The material of the anticathode has little influence on the intensity of the radiation. Expts. on the polarization of the rays and the velocity distribution of the secondary electrons were inconclusive. Whiddington (*C. A.* 7, 1671) considers that the production of X-rays at potentials lower than 200 v. is doubtful.

G. L. WENDT.

The radioactivity of minerals. I. Pyromorphite. M. BAMBERGER AND G. WEISSENBERGER. Vienna. *Monatsh.* 36, 169-74(1915).—The detn. of the Ra and Th content of various pyromorphites from Saxony and Hessen-Nassau shows the same variation in the Ra content and the same absence of U as was found by Danne in pyromorphite from Issy-l'Éveque. The Ra varies between 1.3×10^{-9} and 3.04×10^{-10} g. per g. Danne's suggestion that the presence of Ra is due to absorption from the radioactive ground waters is rejected, since crystalloids do not absorb from such very weak solns. The Ra is supposed to have been included in the crystals at the time of their pptn. The neighboring waters contain Ra but no U. The active crystals showed in every case a green color, the others being brown.

G. L. WENDT.

Adsorption and precipitation of the radioelements. F. PANETH. *Monatsh.* 36, 303-15(1915); see *C. A.* 9, 553.

E. J. C.

The behavior of the radioelements in precipitation reactions. II. K. FAJANS AND F. RICHTER. Karlsruhe. *Ber.* 48, 700-16(1915); cf. *C. A.* 8, 623.—The radioelements can be carried down very completely by other ppts., even though present in quantities far below the solubility value. The degree of extn. of Th B by numerous ppts. is parallel to the solubility of the Th B (or Pb) salts with the pptg. anion, being practically complete with the sulfide, carbonate and sulfate. But the solubility of the common metal ppt. also influences the degree of extn.; and incomplete pptn. of the common metal gives incomplete extn. of the radioelement. These data accord with Haber's theory of crystal growth (*Z. Elektrochem.* 20, 521(1914); cf. *C. A.* 9, 1264). If mols. in crystals are connected on all sides by partial valence bonds there is a layer of free valences at the surface of the crystals to which other mols. become attached. Isomorphous substances fit smoothly into the crystal lattice, forming solid soln.; but when a dissimilar mol. becomes attached, as (Th B)Cl₃ on AgCl, the crystal growth is arrested and adsorption results. Thus either solid soln. or adsorption removes the radioelement from soln. according to the nature of the main ppt.

G. L. WENDT.

The alpha radiation of bismuth from pitchblende. L. MEITNER. Berlin-Dahlem. *Physik. Z.* 16, 4-6(1915).—Fajans has proposed (*C. A.* 9, 1147) the hypothesis of a genetic relationship at the end of the Ra family according to the scheme, $Pb \xrightarrow{\beta} Bi \xrightarrow{\alpha} Tl$. Owing to the apparent long life of Pb and the weakness of its supposed β -radiation one would not expect to throw any light on the truth of the hypothesis by an exam. of the activity of Pb. But Bi might well show an α -ray activity that could be detected. Fajans and Towara (*C. A.* 9, 1147) made some expts. with Bi from Joachimsthal and

found evidence of such an α -radiation. A suspicion that this activity may have been due to an impurity led the author to further expts. with crude Bi from Joachimsthal ore. The purification of the Bi was first made by adding a small quantity of Th to act isotopically with the possible Io; and in fact on removing the Th the α -activity of the Bi was greatly reduced. A series of nine such sepn. reduced the activity to 0.1% of its original value, and even this small remainder of activity was found to have come from the Th and was removed by means of a Zr sepn. The conclusion was reached that Bi does not possess an activity that could be detected by the electroscope used, and certainly does not have an α -radiation of more than 1/10,000 that of U, and all conclusions drawn from its supposed α -activity are invalidated. S. C. LIND.

The magnetic spectrum of the beta rays of radiothorium and thorium X. O. v. BAEYER, O. HAHN AND L. MEITNER. Berlin-Dahlem. *Physik. Z.* 16, 6-7(1915).—The far-reaching parallelism in properties between the members of the Th and Act families which must exist according to the modern views of isotopism has already been demonstrated with respect to the α -radiations of corresponding members of the 2 families. In the β -radiations an apparent difference was reported by the authors (*C. A.* 6, 2356) in that a strong β -radiation was found for Radio-Act which seemed to be lacking in the case of Radio-Th. Since the method of photographing the magnetic spectrum is much more sensitive than the electroscopic method, the question of β -radiation has been again investigated for both Radio-Th and Th X. The latter for photographic purposes can be easily deposited electrolytically on a thin Pt wire as cathode. Radio-Th presents more difficulties and must first be sepd. from Th X and other decomp. products by repeated pptn. with ammonia, followed by addition of a small quantity of Ba salt which is electrolytically deposited with Radio-Th cathodically, using 50-100 v. and 0.01-0.02 amps. In this way a deposit equiv. in β -radiation to about 0.01 mg. of RaBr₂ was obtained on a length of wire of about 0.8 cm. and of 0.15 mm. diam. A 12 hr. exposition of this Radio-Th in a field of 100 Gauss gave a sharply defined reproduction of 2 lines due to β -rays of 0.51 and 0.47 of light velocity, resp. These 2 lines had previously been wrongly ascribed to Th X by the authors, but the discrepancy now is removed. The spectrum of Th X showed 2 strong lines, 0.72 and 0.63 of the velocity of light. S. C. LIND.

A variable resistance for radioactive measurements. M. SIEGBAHN. Univ. Lund. *Physik. Z.* 16, 10(1915).—The variable resistances that have been used in radioactive measurements all have the disadvantage that the electrical capacity also varies when the resistance is changed. S. proposes a vertical cylindrical condenser, consisting of 3 plates arranged horizontally like the 2 plates in an ordinary condenser except that the lower plate is split into 2 slightly sepd. halves, making 2 plates each of which has its own insulation through the case by means of which they are grounded separately. The upper circular plate is also carefully insulated and provided with a handle projecting up through the cover by means of which it can be horizontally rotated to any angle with respect to the 2 lower half-plates. A pointer extending out to the edge of the cover provided with a graduated circular scale provides for setting the plate at any desired position. The lower side of the upper plate is just half covered by a layer of the black oxide of U. It is then, by rotating this active half circle, charged to a suitable potential to produce satn. above the 2 half electrodes; the strength of the current in each of the latter varies in a complementary manner between a max. and minimum which differ from each other by about ten fold and enables the resistance to be varied at will between these limits without changing the electrical capacity. Except near the points of max. and minimum, the current varies proportionally to the angle of rotation. S. C. LIND.

Remarks upon the paper of B. Winawer and F. Pfeiffer on "branching sparks on

Röntgen tubes." B. THIEME. *Physik. Z.* 16, 15(1915); cf. *C. A.* 9, 552.—T. calls attention to his previous description of the same phenomenon under somewhat different exptl. conditions (*C. A.* 6, 1706). S. C. LIND.

The Röntgen ray spectrum of platinum. E. WAGNER. Munich. *Physik. Z.* 16, 30-2(1915).—W. expresses the view that the line spectrum of Pt photographed by Seemann (*C. A.* 9, 175) using a stationary salt crystal as reflecting surface was due to imperfections in the surface of the crystal magnified by its stationary position during the exposure. S. C. LIND.

Röntgen ray spectrography. H. SEEMANN. Würzburg. *Physik. Z.* 16, 32-3 (1915).—S. is not prepared to admit the correctness of Wagner's criticism (preceding abstr.) regarding the line spectrum of Pt. He maintains that the stationary crystal gives much sharper resolution of the lines and attributes the bands obtained when using rotating crystals as reflector to unavoidable vibration and consequent blurring and displacement. S. claims a perfect crystal in his original work and that the crystal employed must have been very defective to give the spectrographs obtained by Wagner. S. C. LIND.

The corpuscular radiation liberated in vapors by homogeneous X-radiation. H. MOORE. King's Coll., London. *Proc. Roy. Soc. London (A)* 91, 337-45(1915).—In a former paper (*C. A.* 8, 1059) it was shown that for C and O, the number of corpuscles liberated from an atom by a beam of X-rays was the same whether the atom is in combination or not. This conclusion has been extended to the cases of N, S and Cl, a close agreement being obtained for each of these in 2 or 3 different combinations, resp.; the values previously obtained for C and O have also been corroborated. In addition it is shown that the at. corpuscular radiation, *i. e.*, the corpuscular radiation from an atom, is approx. proportional to the 4th power of the wt. of the atom, the deviation in the observed values from this 4th-power law being of such a character as to suggest that they are merely due to exptl. errors. From the observations of Barkla and Simons (*C. A.* 6, 1242), and Barkla and Philpot (*C. A.* 7, 3077), it is shown that the coeff. of absorption of a beam of X-radiation in a gas is proportional to the quantity of electronic radiation liberated from the gas, and hence the X-radiation absorbed by an atom of a given element will also be proportional to the 4th power of the wt. of the absorbing atom. Recent expts. of Bragg and Pierce (*C. A.* 9, 21) show that a similar law holds good for elements in the solid state, and is therefore probably of universal application. It is therefore considered that it should be possible to calculate the absorption coeff. of any material, provided its homogeneous radiation is not excited. W. H. ROSS.

Brit., 1,173, Jan. 15, 1914. E. EBLER. Radium and mesothorium salts. Crude sulfates containing Ra or Meso-Th sulfates are reduced to sulfides by heating with CaC_2 or its ingredients. The reaction may be effected without heating if a part of the carbide is replaced by CaH_2 , Ca, Mg, Al, or other substance that will react with sulfates in the manner of an aluminothermic mixt.; or CaH_2 or Ca together with an equiv. quantity of a sulfate, may be added to the mixt. of CaC_2 and crude sulfates. The reduced mass is dissolved in H_2O , HCl , or HOAc , and the Ra or Meso-Th and Ba are pptd. by satg. the soln. with HCl or HNO_3 . Practically all the Ra or Meso-Th salt is deposited before the whole of the Ba salt. Cf. *C. A.* 9, 1150.

Electric melting of ferro-alloys. R. S. WILE. *Iron Age* 95, 1068-9(1915).—Addition of melted alloy is preferred because the temp. of the metal in the ladle is not reduced, and the metal is saved. The elec. furnace is best adapted to melting the alloys. See C. A. 9, 1581. H. V. MAIN.

Steel from ore. C. OTTO. *Feuerungstechnik* 3, 129-31(1915).—A criticism of a process for producing steel directly from the ore by means of an elec. furnace as advanced by Humbert and Hethey (cf. C. A. 8, 2848). H. R. GUNDLACH.

The fixation of atmospheric nitrogen. W. S. LANDIS. *Met. Chem. Eng.* 13, 213-20(1915); *J. Ind. Eng. Chem.* 7, 433-8(1915); *Am. Fertilizer* 42, No. 9, 21-6(1915).—An illustrated lecture. The present com. methods of N fixation are first described. The cyanamide reaction and the properties, uses, and manuf. of cyanamide are then taken up with special reference to the Niagara Falls plant of the American Cyanamid Co. The plant at present has an output of 64,000 tons of cyanamide per year. The CaC_2 required is manufactured in eight 20-ton, 3000 h. p. three-phase continuous electric furnaces. The lime is burned in twelve Doherty-Edwards lime-kilns operated with induced draught. N was formerly obtained from air by absorbing the O_2 in Cu sponge which was then regenerated by coal-gas. The latest extension is supplied with N_2 obtained by the fractional distn. of liquid air produced by the Claude process. The coal-gas plant, which furnishes part of the coke needed for the carbide, has a capacity of 500,000 ft. per 24 hrs. The retort benches are run very hot to produce a gas rich in H_2 and coke low in volatile matter. The cyanamide reaction is carried out in small individual ovens holding 0.5-2.5 tons of carbide each. The product from the ovens analyzes about 22% N and 1% un-nitrified carbide. This material is ground, partially hydrated to decompose carbide, oiled to render dustless, and then is ready for use in mixed fertilizers. The production of other N compds. from cyanamide is discussed briefly. Many illustrations of plant details are given. F. A. STRAUSS.

The cyanamide process. FRANK S. WASHBURN. *Met. Chem. Eng.* 13, 309-14 (1915); *Elec. World* 65, 729(1915); see C. A. 9, 1362. F. A. S.

The cathodic deposition of metals in the presence of organic bases. I. Zinc. ARRIGO MAZZUCHELLI. *Univ. Rome. Atti accad. Lincei* 23, II, 503-8(1914).—M. recently observed (C. A. 9, 1008) that quinine has the same effect as gelatin and other colloids on the cathodic deposition of Sb and now reports the same effect with other organic bases. The electrolytic ptn. of Zn from portions of solns. of 150 g. cryst. $\text{ZnSO}_4 + 50 \text{ g. } (\text{NH}_4)_2\text{SO}_4$ in 1 l. H_2O was studied. An As-free Zn rod was the anode and a brass plate the cathode. Quinine, cinchonine, quinoline, dimethylaniline, α -naphthylamine, lutidine, aniline and pyridine were the bases added. In general when a small amt. of the base was added, or, in all cases during the first moments of electrolysis, a uniform, homogeneous, fine-grained deposit of microscopic crystals was formed. On continuing the electrolysis or with larger c. d. the Zn is sepd. unevenly in cryst. warts. In the case of gelatin the first effect is more pronounced. The mechanism of the process in general is this: the base or its cation is absorbed by the metallic granules that are first pptd. and keeps the granules fine according to the theory of Muller and Bahntje. On continuing the electrolysis the organic compd. covers the cathode like a varnish and makes it passive except at a few thinly covered spots. At these the deposition continues and produces the warty deposits. It depends on the amt. of the base absorbed in the beginning, on its capacity for redissolving in part

and on its greater or less impermeability whether the favorable influence exercised at first is changed to a harmful one. Since no similar retardation of the rate of soln. of the Zn anode takes place, the electrolytic soln. of the anode is an irreversible process in the presence of organic bases; a soln. containing such a base when electrolyzed between 2 Zn electrodes will give a continuous stream of H_2 with an a. c. (42 cycle). Measurements showed that this evolution of H proceeds at an overvoltage of 0.130-0.180 v. The author intends to extend the expts. to various bases and metals. II. *Ibid* 626-33. M. here reports quant. data. A careful review is given. M. has measured the voltage during the passage of a current of known d. and also the voltage when the soln. is at rest, using a Zn coated brass cathode and a solid Zn anode in the $ZnSO_4 + (NH_4)_2SO_4$ soln. The expts. were made at 11° in contact with the air, without a diaphragm, but with constant stirring. The electrode potential was measured by the usual compensation method, using a Weston cell and measuring the v. between the electrode and a 9% Zn amalgam in an equiv. N $ZnSO_4$ soln. The $ZnSO_4$ soln. was electrolyzed without additions, with 5×10^{-5} parts of quinoline sulfate, with 5×10^{-4} parts quinine bisulfate and with 1% quinine bisulfate and with 1×10^{-4} gelatin under various c. d.'s and at a max. v. of 0.022. The potentials of the anode and cathode were measured before passing the current, during the passage of the known current and after shutting off the current. The individual potentials are higher during electrolysis than when the soln. is at rest. With gelatin the excess potential is comparatively small which is in accordance with the fact that it shows less tendency to give a warty deposit.

5. PHOTOGRAPHY.

LOUIS DERR.

Retardation of development by sodium phosphate. H. LÜPPO-CRAMER. *Phot. Korr.* 52, 35-6(1915).—A marked retardation (about equal to that produced by K citrate) is caused by adding Na_2HPO_4 to either hydroquinone or pyro developers.

L. DERR.

Acceleration of reduction of ferrous sulfate-silver salts by acids. H. LÜPPO-CRAMER. *Phot. Korr.* 52, 36-7(1915).—The acceleration of development caused by acetic acid is the more remarkable because oxalic and tartaric acids have the opposite effect.

L. DERR.

Testing of paper for the blue print process. E. VALENTA. *Phot. Korr.* 52, 57-8 (1915).—One part green ammonio-ferric citrate in 4 of water is added to 1 of $K_4Fe(CN)_6$ in 7 water, and the whole diluted 3- to 4-fold. Strips of the paper to be tested are immersed in the soln., which is then brought to a boil. Good paper will show little or no blue coloration; unsuitable paper will be more or less strongly dyed blue.

L. DERR.

Developers giving brightly tinted images on silver bromide dry plates. E. VALENTA. *Phot. Korr.* 52, 58-60(1915).—The best results were obtained by the following: 0.5 g. hydroquinone, 4 g. Na_2SO_3 crystals, 6 g. $(NH_4)_2CO_3$, 100 cc. water. This gives a practically white image, which on a black background shows good gradation and no fog. Pyrocatechol and glycine are less satisfactory. These are available for tintype work.

L. DERR.

4-Hydroxyphenylmethylglycine as a developer. E. VALENTA. *Phot. Korr.* 52, 90-2(1915).—In developing properties, this new Agfa product lies between metol and glycine. It gives clear negatives of good gradation, and is well adapted to both gelatin and collodion plates.

Graphite, diamond and amorphous carbon. W. A. ROTH AND H. WALLASCH. Greifswald. *Z. Elektrochem.* 21, 1-5(1915); cf. *C. A.* 7, 2507.—Additional measurements, now including 15 different specimens of graphites, confirm the higher heat of combustion of diamond (7869 ± 3). Two varieties of graphites are now with certainty differentiated: α (7830-40), which includes natural graphites, formed probably at high pressure and moderate temp.; β (7856), including all artificial graphites (high temp., low pressure). A very pure but imperfectly cryst. specimen from Ticonderoga gave 7848 ± 1 , independent of preliminary treatment for removal of impurities, indicating either a third variety or a mixt. of the α and β varieties. Pure, amorphous, thermally well defined carbon cannot be prepd. A qual. discussion of the stability relations of the various forms of C is presented; more definite data on the compressibilities are required before the equil. conditions can be accurately defined. The distinction between α and β graphites is in no way related to the older distinction of graphite and graphitite.

A. R. MIDDLETON.

Photochemical reactions of compounds of the rarer elements. A. BENRATH. *Z. wiss. Phot.* 14, 217-22(1915).—Thallium bromide and iodide are unaffected by exposure to light; TiCl_3 either dry or under water, assumes a brown color, due probably to the formation of the insol. sesquichloride $\text{TiCl}_3 \cdot 3\text{TiCl}$. Reducing agents, such as oxalic, tartaric and citric acids, and alcohols reduce Tl halides to metal, the chloride rapidly though incompletely, the bromide less rapidly, and the iodide very slowly; the sulfate is stable. Oxalic acid is reduced by TiCl_3 into CO_2 and H in 3 stages. Thallous salts are more easily reducible than thallic salts. The reduction of Ce salts is accelerated by light. Titanium oxide, sulfate and tetrachloride in alc. or $(\text{COOH})_2$,

slowly turn blue or brown, as simple or complex salts are formed. Compds. of Te and Se are reduced by $(\text{COOH})_2$ to metal, and SO_2 is slowly reduced to S. Iridium ammonium chloride slowly dissolves in $(\text{COOH})_2$, giving first a brown tint, then a clear soln. with black Ir powder.

ISADOR MILLER.

The preparation of a finely porous asbestos filter and its use. J. GROSSFELD. *Z. Nahr-Genussm.* 29, 67-8(1915).—G. advises the use of com. infusorial earth (which has been ignited and boiled with HCl) over the asbestos mat in the Gooch crucible. He finds that a crucible so prepared will filter BaSO_4 pptd. in the cold, S from thiosulfate, etc. He recommends its use in the detn. of Ca as $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$, which can be filtered directly and dried at 120° and weighed as such.

H. L. LOURIE.

The value of counting particles of finely divided substances. CURT KÜHN. *Z. angew. Chem.* 28, I, 126-8(1915).—The Zeiss-Thoma hemacytometer employed in counting blood corpuscles may be used to advantage in examg. paint pigments and similar substances. A sample of 1-5 g. is shaken for 15 min. in a 10 cc. measuring cylinder with the proper liquid (turpentine, glycerol, H_2O or hydrocarbons) and 0.01 cc. of this removed with a micro-pipet. This is dild. to 1 cc. and shaken for 15 min. One drop of this is put upon the object glass and allowed to stand from 1 to 12 hrs. to settle. The best results are obtained with 10-20 particles to 0.00025 of a cu. mm. The method is adapted to the detn. of the efficiencies of grinding machinery and of ignition processes, to the grading of paint pigments, to the estn. of impurities in dry mixtures, and the like, as well as to measurement of the vol. and wt. of single particles. The order of magnitude of measurable units reaches 1 g. = 2000×10^8 .

H. L. OLIN.

Metal titration with arsenic acid. J. VALENTIN. Tilsit. *Z. anal. Chem.* 54, 76-89(1915).—The method is based on the pptn. of the metal as an insol. arsenate with excess K_2AsO_4 soln., and titration of the excess in an aliquot portion of the filtrate. Mg is pptd. as $\text{MgNH}_4\text{AsO}_4$; the best conditions for the estn. of up to 0.04 g. Mg are to add to 50 cc. standard 1% K_2AsO_4 soln., 10 cc. 10% NH_4OH soln., 10 cc. 5% NH_4Cl soln., heat to boiling, add the Mg soln., let stand 2 hrs. and titrate. For Ca, pptd. as $\text{CaNH}_4\text{AsO}_4$, add to 50 cc. K_2AsO_4 soln. 10 cc. 10% NH_4OH , filter and titrate after 24 hrs. In each of the above cases excess acid must be removed by evapn. before the titration. For Sr and Ba the procedure is the same as for Ca, except that the soln. may be titrated after 12 hrs., and that excess acid may be neutralized by evapn. Zn and Cd are pptd. as $\text{Zn}_3(\text{AsO}_4)_2$ and $\text{Cd}_2(\text{AsO}_4)_3$, resp.; to 50 cc. arsenate soln. add 0.5 g. NaHCO_3 and 10 cc. of the acid-free (neutralize with NaHCO_3) Zn or Cd soln., containing up to 0.1 g. Zn or 0.2 g. Cd, titrate after a few min. Pb is pptd. as PbHAsO_4 ; add NH_4OH to the Pb soln., containing up to 0.3 Pb, until alkaline, acidify with AcOH , add to 50 cc. 1% arsenate soln. and titrate after 3 hr. Bi is pptd. as BiAsO_4 in the presence of a little free HNO_3 ; free HCl or H_2SO_4 give low results. Al is pptd. as $\text{Al}(\text{AsO}_4)_2(\text{OH})_3$; make the Al soln., containing not more than 0.05 g. Al, ammoniacal, acidify with AcOH , add 50 cc. 1% arsenate soln. containing 5 g. NaOAc , and titrate

after 12 hrs. Cr is pptd. as CrAsO_4 ; make the Cr soln. alk. with NH_4OH , acidify with AcOH , add 50 cc. arsenate soln., heat 10 min., cool, titrate. Mn is pptd. as $\text{MnNH}_4\text{AsO}_4$; add the Mn soln., containing up to 0.1 g. Mn, to 50 cc. arsenate soln., add a few cc. 5% NH_4Cl , neutralize carefully with NH_4OH , heat 30 min. on the water bath to remove excess NH_4OH , cool and titrate. Ni and Co are pptd. as HNiAsO_4 and HCoAsO_4 ; add the soln. containing not more than 0.05 g. Ni or Co to 50 cc. arsenate soln. containing 10 g. NaOAc , heat 1 hr., cool and titrate. Results given are in general a little low.

G. W. MOREY.

Analysis of nitrites. N. BUSVOLD. *Chem. Ztg.* 39, 214(1915).—B. proposes the following modification of Raschig's method: Add 50 cc. 0.1 N KMnO_4 to 34–35 cc. of nitrite soln. (5 g. per l.) and acidify with 20 cc. 0.2 N H_2SO_4 added drop by drop with shaking. Allow the soln. to stand 2–3 min. to complete the oxidation of HNO_2 , add 5 cc. of 10% KI soln. and titrate the free I_2 with 0.7 N $\text{Na}_2\text{S}_2\text{O}_3$ of which not more than 1–3 cc. should be used. The acid must be added with care; no evolution of oxides of N (indicated by starch iodide paper) must take place. As an alternative B. uses the (AgBrO_3) method; cf. C. A. 8, 1250.

H. L. OLIN.

The separation of the alkaline earth metals and the alkalis. R. GILMOUR. *Chem. News* 111, 217(1915).—Evap. the filtrate from the Fe group to dryness and ignite residue. Dissolve in 10 cc. H_2O with 2 drops of HCl . Heat to boiling. Add 5 cc. NH_4Cl soln., 5 cc. NH_4OH and 10 cc. $(\text{NH}_4)_2\text{CO}_3$ soln., heat for a few min., filter and wash. Filtrate = Group V. Ppt. = BaCO_3 , SrCO_3 and CaCO_3 . Dissolve the ppt. in 4 cc. hot AcOH , neutralize with NH_4OH and add an excess of 2 cc. AcOH . Dil. to 20 cc., heat to boiling and add an excess of K_2CrO_4 soln. Heat for 2 min. and filter. Ppt. is BaCrO_4 . Heat filtrate to boiling, add $(\text{NH}_4)_2\text{CO}_3$ soln. until soln. is yellow and then 4 cc. excess. Heat for a few min., filter and wash. Ppt. is SrCO_3 and CaCO_3 . Dissolve in hot AcOH and make alk. with NH_4OH . The vol. of the soln. should now be about 4 cc. To half the soln. add a satd. soln. of CaSO_4 and heat to boiling. Ppt. is SrSO_4 . To the other half add a strong soln. of $\text{K}_4\text{Fe}(\text{CN})_6$ and boil. Ppt. is Ca K ferrocyanide. Evap. filtrate containing Group B to 10 cc. Add 4 cc. $(\text{NH}_4)_2\text{CO}_3$ soln. and 15 cc. EtOH . Allow to stand 15 min. Rub with glass rod if necessary to start crystn. Ppt. is MgCO_3 . Identify K and Na in filtrate as usual.

E. W. BOUGHTON.

A new method for the analysis of the copper and tin groups. R. GILMOUR. *Chem. News* 111, 206–8(1915).—The objectionable features of existing methods are discussed. An outline of G.'s new method is as follows: Ppt. the metals of Group II as usual with H_2S . Treat the sulfides with boiling 5 N HCl , which decomposes all except HgS , CuS and As_2S_3 . Sep. the As_2S_3 by treating with NaOH . Boil the filtrate containing Pb, Cd, Sn, etc. to remove H_2S , add 15–20 cc. of H_2O_2 soln. and evap. the mixt. nearly to dryness to remove excess of acid. Any Sn^{IV} is in this way oxidized to Sn^{IV} . Dissolve the residue in H_2O and ppt. the metals with H_2S . Remove Sb_2S_3 and SnS_2 by treatment with NaOH . In sepg. Bi and Pb advantage is taken of the insolubility of BiCrO_4 and the solubility of PbCrO_4 in NaOH . Details for detecting all the metals of Group II are given.

E. W. BOUGHTON.

Precipitation of phosphorus as ammonium phosphomolybdate in the presence of sulfuric acid. K. G. FALK AND KANEMATSU SUGIURA. *J. Am. Chem. Soc.* 37, 1507–15(1915).—The ppt. of NH_4 phosphomolybdate in the presence of H_2SO_4 (as in Neumann's method) contains sulfate, apparently as an essential part of the mol., together with excess of MoO_3 and no HNO_3 . The comp. of this phosphosulfomolybdate ppt. may vary with the concn. of the different constituents of the soln. For a certain set of conditions the ppt. was found to be $4[(\text{NH}_4)_3\text{PO}_4 \cdot 12\text{MoO}_3] + (\text{NH}_4)_2\text{SO}_4 \cdot 5\text{MoO}_3$.

E. B. MILLARD.

After-coloring in iodometric titrations. A. KOLB. *Chem. Ztg.* 39, 299-300(1915); cf. C. A. 2, 2525; Müller, C. A. 9, 768. J. H. MOORE.

Application of entrainment reactions to the detection and determination of traces of substances in mixtures; application to researches on the toxicology of lead. G. MEILLÈRE. *Ann. chim. anal.* 20, 73-7(1915).—A general discussion of the application of entrainment to chem. analysis is given. M. states that he has been able to det. Hg in chloride waters by adding a salt of Cu and pptg. with H_2S , subsequently sepg. the Cu and Hg in the ppt. If a Zn salt is used instead of Cu, the subsequent sepn. of Zn and Hg can be conveniently made electrolytically. Similarly Zn in a water was detd. by pptg. with Fe or Cu, finally sepg. the Zn electrolytically. The detn. of Pb in waters is made as follows: Add to the sample exactly 25 g. of a Cu salt for each liter of sample. Pour the soln. into the pptn. flask and rinse the original container with 10 cc. of HCl for each liter of sample. Pass H_2S into the cold soln., at first avoiding an excess. Finally warm on the steam bath and pass in a rapid current of H_2S . Filter through a pad of filter paper or asbestos and wash with warm H_2O . Dissolve the ppt. in concd. HNO_3 and evap. the soln. to dryness, finally heating until the $Cu(NO_3)_2$ is all decompd., thus destroying org. matter. Add HNO_3 and electrolyze a soln. containing not more than $1/11$ its vol. of free HNO_3 at a temp. not above 40° , using about 2 v. and less than 0.2 amp. Spirals of Pt wire weighing 2-4 g. may be used as electrodes. When Pb is pptd. with CuS in dil. HCl soln., as above, Zn, Fe and Mn, if present, are not pptd. The method is especially applicable to studies on the toxicology of lead.

E. W. BOUGHTON.

The volumetric determination of the higher oxides of lead and manganese with titanium trichloride. L. MOSER. *Chem. Ztg.* 39, 245-7(1915).—(1) *Detn. of PbO_2 and Pb_2O_4 .* $TiCl_3$ reduces the higher oxides of Pb according to the equation: $PbO_2 + 2Ti^{+++} + 4H^+ = Pb^{++} + 2Ti^{++++} + 2H_2O$. Should the concn. of H^+ be too high, Cl_2 is liberated. Shake the sample with 100 cc. H_2O and boil to expel dissolved O_2 . Pass in CO_2 and add an excess of standard $TiCl_3$ soln. (1 cc. = 0.005 g. Fe) quickly with shaking. Titrate the excess of $TiCl_3$ with standard $FeCl_3$, using KCNS or methylene blue as indicator. (2) *Detn. of MnO_2 .* To 0.1-0.3 g. pyrolusite add a large excess of $TiCl_3$ soln., and run through a current of CO_2 ; add 40-50 cc. HCl (d. 1.19) from which air has been boiled out. Boil the mixt. gently until the MnO_2 is in soln.; then titrate with $FeCl_3$ soln. using methylene blue.

H. L. OLSEN.

Electrolytic separation of palladium and tin. A. GUTBIER, C. FELLNER AND R. EMSLANDER. *Z. anal. Chem.* 54, 208-13(1915).—A combination of the methods of Wöhler and Spengel (C. A. 5, 2047, 2474) and Amberg (*Z. Elektrochem.* 10, 386, 853 (1904)) gave good results for Pd, but there was some loss of Sn due to the colloidal character of the stannic acid, even after long boiling with NH_4NO_3 . The following method based on G.'s previous work and that of Langness (C. A. 2, 45) gave excellent results for Pd and fairly good for Sn; let the soln. of the 2 metals flow slowly with vigorous stirring into an excess of NH_4OH and heat with stirring to incipient boiling to effect a complete soln. of the Pd compd. Cool to 60° , hold at this temp. and electrolyze, adding NH_4OH from time to time to replace that evapd. Use Pt electrodes and rotate at 2400 r. p. m. with at least 2 v. and 0.2 amp. Owing to the rapid stirring, the H bubbles developed on the cathode are immediately removed, resulting in a very adherent deposit of Pd. The Sn is pptd. by NH_4NO_3 from the residual soln. and detd. in usual manner. Results are reported by both of the above methods. In H_2SO_4 soln. at 18° with 2400 r. p. m. it was found that 0.27-0.41 amp. and 1.9-3.0 v. gave adhering deposits of Pd; with 0.69 amp. and 3.6 v. the deposit flaked off somewhat; with 0.75 amp. and 4.0 v. decided scaling occurred. Adhering deposits of Pd were obtained in

NH₄OH soln. at 65° and 2400 r. p. m. with 0.14 to 1.65 amp. and 1.2 to 7.0 v. Results are reported. F. W. SMITHER.

The separation of palladium and tin by means of dimethylglyoxime. A. GUTBIER AND C. FELLNER. *Z. anal. Chem.* 54, 205-8(1915).—Dissolve the Pd containing Sn in *aqua regia*, expel free Cl and dil. the soln. of PdCl₂ and SnCl₄ to at least 150 cc., heat on water bath and add 1% dimethylglyoxime soln. (in alc. or HCl), with stirring till ppt. no longer forms, and heat till settled. Cool to room temp., filter and wash with dil. HCl (not over 2%), ash and burn in a Rose crucible, finally igniting in H₂; weigh as Pd. In the filtrate from the C₄H₉N₄O₂Pd ppt., sep. the Sn as metastannic acid, finally weighing as SnO₂ in usual manner. Excellent results are reported on known mixts. of Pd and Sn. F. W. SMITHER.

Gravimetric determination of selenium. A. GUTBIER AND F. ENGEROFF. *Z. anal. Chem.* 54, 193-205(1915).—A critical review and discussion of the subject, especially of a paper by J. Meyer (cf. *C. A.* 8, 1721). It is stated that the work of G. and his co-workers antedates that of M. A study of the detn. of Se in the presence of org. protective colloids is the basis of the present paper; such materials require the use of HNO₃. In some cases a simple heating with concd. HNO₃ suffices to yield a colorless soln., while others require treatment by the Carius method. KCl added to concd. HCl solns. of SeO₂ does not form K₂SeCl₄ or prevent volatilization of Se. The formation of H₂SeCl₄ by action of concd. HCl on SeO₂ is improbable or the hydrolysis of the H₂SeCl₄ is practically instantaneous. Exptl. proof shows the impossibility of forming H₂SeCl₄ from SeCl₄ by action of concd. HCl; therefore equil. in the system SeO₂-concd. HCl may be expressed: $\text{SeO}_2 + 4\text{HCl} \rightleftharpoons \text{SeCl}_4 + 2\text{H}_2\text{O}$ and $\text{SeCl}_4 + \text{H}_2\text{O} \rightleftharpoons \text{SeOCl}_2 + 2\text{HCl}$. In pptg. Se by means of a reducing agent it does not sep. first in the red amorphous form, but as red colloidal Se, which, according to the temp., quickly or slowly coagulates into the red amorphous form; on continued heating the latter is transformed into the gray or black modification. Most of the ppt. settles, but a "skin" of gray Se floats on the soln. G. prefers to add the reducing agent and then heat, working in an Erlenmeyer flask or covered beaker. Expts. are reported on a specially prepd. SeO₂ soln., using varying concs. of HNO₃ and reducing with hydrazine hydrate (10% soln.) and with a cold satd. soln. of hydrazine sulfate; same after neutralizing with NH₄OH; also after neutralizing with NH₄OH and then adding varying amts. of 10% HCl. These expts. give excellent results, confirming previous work (*Z. anorg. Chem.* 41 291(1904)). Results are reported showing loss with varying concs. of HNO₃ and varying time periods up to 6 hrs. on the water bath before reduction. The numerous references to and quotations from the literature are noteworthy. Cf. *C. A.* 7, 3697; 9, 1142. F. W. SMITHER.

The estimation of pentavalent vanadium by means of sodium thiosulfate. G. O. OBERHELMAN. *Yale Univ. Am. J. Sci.* 39, 530-4(1915).—The method is based on the reduction of V₂O₅ salts to V₂O₄ by excess Na₂S₂O₃ in the presence of a Cu salt as accelerator, and titration of the excess Na₂S₂O₃ with I soln. In HCl soln. the best conditions were found to be the following: The vanadate soln. is brought to a vol. of 800 or 400 cc., 10 or 5 mg. CuSO₄·5H₂O and 3 or 1.5 cc., resp., of 32% HCl added, 0.1 N Na₂S₂O₃ run in until an excess of 15 or 7.5 cc., resp., are added, the soln. let stand until the color is a pure sky blue, KI added to amt. of 0.1 g. per 100 cc. of soln., and excess Na₂S₂O₃ titrated with I soln. The V blue does not interfere with the starch end point. Results given are satisfactory. G. W. MOREY.

Simplified ferrous sulfate method for the determination of vanadium in steel. G. T. DOUGHERTY. *J. Ind. Eng. Chem.* 7, 419-20(1915).—Treat 2-4 g. drillings in a 500 cc. Erlenmeyer flask with 60 cc. H₂O and 10 cc. concd. H₂SO₄. After heating the soln. nearly to boiling, until the reaction is complete, add 40 cc. HNO₃ (1.20) and boil

10 min. Cool, add 60 cc. cold H_2SO_4 (1:2) and dil. to 450 cc. Add 3 cc. 1% $\text{K}_2\text{FeC}_2\text{N}_6$ and titrate rapidly (with stirring) with 0.05 N $\text{FeSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$ to the appearance of the first dark blue color. Deduction of a blank of 0.4 cc. is necessary up to 0.5% C, and more with higher C content. In the latter case masking of the end point may be avoided by adding to the soln. after boiling with HNO_3 , 60 cc. H_2SO_4 (1:2) and 5-8 g. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and boiling for 15 min. Cool, dil. and proceed as above. The method is accurate to 0.01% V.

ISADOR MILLER.

Permanganate and iodometric determination of iodine in the presence of bromides and chlorides. O. L. BARNEBEY. *J. Am. Chem. Soc.* 37, 1496-507(1915).—Results obtained by the original Pean de St. Gilles method for I in the presence of bromide or chloride are incorrect because of the formation of free Br and Cl or HClO . The presence of MnSO_4 and H_3PO_4 in the ferrous soln. allows the removal of the excess KMnO_4 and MnO_2 without liberation of free Cl or Br from the halides, and insures a correct titration of the ferrous Fe excess. I may be detd. in the presence of bromide or chloride by addition of KI to the final soln., and titration of the liberated I with $\text{Na}_2\text{S}_2\text{O}_3$. Both titrations can be made on a single sample.

E. B. MILLARD.

Permanganate determination of iron in the presence of fluorides. Analysis of silicates and carbonates for their ferrous iron content. O. L. BARNEBEY. *J. Am. Chem. Soc.* 37, 1481-96(1915); cf. *C. A.* 8, 2989.—Titration of ferrous Fe by KMnO_4 in the presence of fluorides gives an unstable end point, the instability increasing with increased concns. of Fe and HF. H_2SO_4 at N to 5 N permits a good titration; H_3PO_4 cannot be substituted for H_2SO_4 in the titration. $\text{Fe}_2(\text{SO}_4)_3$ and MgSO_4 check the influence of HF in the titration, and MoO_3 and TiO_2 also help, the TiO_2 being better than MoO_3 . Boric and silicic acids also prevent the action of HF, H_2BO_3 being the best reagent tried. Ferrous solns. in the presence of fluoboric acid are stable in air.

E. B. MILLARD.

Estimation of cobalt in high-speed steels. L. DUFFY. *J. Iron Steel Inst.* 90, 52-65(1914); *J. Chem. Soc.* 108, II, 69-70(1915).—Neither the cyanide nor the nitrite method gives good results for Co in high-speed steels. D. recommends the following method: Dissolve 3 g. of drillings in 50 cc. conc. HCl , oxidize with a slight excess of HNO_3 , and evap. to a sirup with an additional 20 cc. conc. HCl . After mixing with 5 vols. of 5% HCl , filter through pulp and wash the tungstic acid with dil. HCl . Neutralize the filtrate, while hot, with NH_4OH and $(\text{NH}_4)_2\text{CO}_3$, add 20 cc. of 33% AcOH and add boiled AcONH_4 soln. to the boiling soln. Make vol. up to 750 cc., filter and collect 500 cc. of filtrate. Ppt. contains Cr, Mo, V and Fe. Filtrate contains Co, Ni and Mn. Remove last traces of Fe from filtrate by adding 5 cc. HCl , evapg. and pptg. with NH_4OH . Repeat this pptn. Neutralize united filtrates with AcOH , adding 4 cc. excess and 15 cc. of AcONH_4 soln. Ppt. Co by passing rapid stream of H_2S for 15 min. Wash CoS with H_2O containing AcONH_4 . Mn may be detd. in filtrate. Dissolve CoS in HNO_3 , any residue being ignited, dissolved and added. To soln. add 20 cc. HCl , and, after evapg. to 10 cc., dil. and ppt. by adding 1 g. $(\text{NH}_4)_2\text{HPO}_4$ and just enough NH_4OH to give a ppt. in hot soln., followed by 15 cc. of AcONH_4 soln., after which NH_4OH is added drop by drop until soln. is faintly alk. On stirring the flocculent blue ppt. becomes pink and cryst. After heating for 15 min. on the steam bath, filter and ignite ppt. of CoNH_4PO_4 to $\text{Co}_3\text{P}_2\text{O}_7$. A minute amt. of Co remains in the filtrate and may be recovered by H_2S . Ni, if present, is sepd. by means of dimethylglyoxime after the acetate sepn. The excess of dimethylglyoxime is removed by HNO_3 before pptg. Co.

E. W. BOUGHTON.

Rapid electrolytic determination of copper. WALTER THEEL. *Chem. Ztg.* 39, 179(1915).—The deposition is very rapid at ordinary temp. if strong solns. are used: 1 hr. for 1.3 amp., 45 min. for 2 amp. Dissolve 1 g. brass in 8.5 cc. H_2SO_4 (1:4) plus

2.5 cc. concd. HNO_3 . Heat gently to boiling till nitrous fumes are driven off, cool, dil. to 25 cc. and electrolyze with gauze electrode. Cf. C. A. 7, 3584. J. H. M.

New test for copper. W. G. LYLE, L. J. CURTMAN AND J. T. W. MARSHALL. *J. Am. Chem. Soc.* 37, 1471-81(1915).—An aq. soln. of $\text{CH}_3(\text{CH}_2)_4\text{CHNH}_2\text{COOH}$ was found to give a positive test for Cu when 1 part in 353,000 was present. With this reagent 0.004 mg. may be detected with certainty, and small amts. of Fe do not interfere as with the ferrocyanide test. Hg and Zn are the only common metals which yield a ppt. under the conditions specified; the interference of the former may be overcome by the addition of NaCl, and the latter may be prevented from pptg. by adjusting the acidity of the soln. E. B. MILLARD.

Brass analysis. BERTHOLD KOCH. *Chem. Ztg.* 39, 215(1915).—Treat 1 g. of brass turnings with 15 cc. H_2SO_4 (1:1) and 10 cc. HNO_3 (d. 1.20) and dissolve over the water bath. Then heat over a flame to expel the HNO_3 fumes, continuing with a low flame until most of the HNO_3 has been expelled and ZnSO_4 begins to sep. After cooling the soln., add 150 cc. H_2O to dissolve the crystals and then heat soln. to the temp. necessary for the Cu detn. as outlined in the preceding paper (C. A. 7, 3584). After sepg. the Cu, cool the soln. to 30-35° and add 18 g. solid NaOH. After dissolving the $\text{Zn}(\text{OH})_2$, add 5 g. KCN, heat to 70° and ppt. Zn on a coppered or silvered electrode at 3-5 amp., 6 v. H. L. OLIN.

Determination of zinc in ores and pyrites cinders. HANS RUBRICIUS. *Chem. Ztg.* 39, 198(1915).—The method is rapid and accurate with small amts. of Zn. Dissolve 5 g. pulverized ore in 15 cc. concd. HCl in a 200 cc. beaker on hot plate for 15 min., then add a few cc. concd. HNO_3 and evap. soln. carefully to a small vol. (not to dryness), cool, add 30 cc. conc. NH_4OH and stir well with a "policeman." The ppt. is treated with NH_4OH 2 or 3 times, the exts. filtered into a 400 cc. beaker and the ppt. washed with hot H_2O . If the filtrate is not blue from the presence of Cu add a few drops of dil. CuSO_4 soln., heat to boiling and ppt. with a little Na_2S , let settle, filter promptly, wash sulfides with hot H_2O , treat at once with hot dil. HCl to dissolve the ZnS, wash remaining CuS, ppt. Zn from the boiling soln. with Na_2CO_3 and weigh as ZnO. If Mn is present it is removed from the mixed sulfides by treating with dil. AcOH before treating with HCl. J. H. MOORE.

Solution control in ferric chloride leaching of sulfide copper ores. F. N. FLYNN AND R. H. HATCHETT. *Met. Chem. Eng.* 13, 291(1915).—When chalcocite is decomposed by FeCl_3 , the resulting soln. may contain Fe' , Fe'' , Cu' and Cu'' . The method for the analysis of the soln. is as follows: **Total Fe:** To a measured quantity of the neutral soln. add a little HCl. Boil with test Pb to ppt. Cu and to reduce Fe. Filter and titrate the Fe in the filtrate with standard soln. of $\text{K}_2\text{Cr}_2\text{O}_7$ or KMnO_4 . **Fe'' and Fe' :** To a second measured portion of the cold neutral soln. add an excess (2 or 3 g.) of pptd. CaCO_3 and stir vigorously for 2 or 3 min. Fe'' is pptd. Filter and det. Fe in the ppt. and in the filtrate, the latter being Fe' . This sepn. with CaCO_3 must be made cold. **Total Cu:** Det. total Cu by any reliable method. A rapid method is as follows: Measure a third portion of the original soln. and oxidize it with KClO_3 and HCl. Neutralize with Na_2CO_3 , acidify with AcOH, and add 2 or 3 g. of Na_2HPO_4 to ppt. Fe. Add 3 or 4 g. of KI and titrate with a standard soln. of $\text{Na}_2\text{S}_2\text{O}_3$. **Cu' and Cu'' :** To a fourth measured quantity of the soln. add HCl and 3 or 4 g. of KI. Dil. and det. total oxidizing power by titrating with standard soln. of $\text{Na}_2\text{S}_2\text{O}_3$. This titration measures Fe'' and Cu'' together. From the buret reading subtract the equiv. of the Fe'' already detd. and calc. the difference as Cu'' . Sometimes the end point is not permanent in the $\text{Na}_2\text{S}_2\text{O}_3$ titration for Fe and Cu. To check the result another sample may be measured and the total reducing power detd. by titrating in a H_2SO_4 soln. with a standard soln. of KMnO_4 . This titration gives Cu' and Fe' together. The equiv. of Fe' ,

already detd., is deducted from the buret reading and the difference calc. as Cu' present as CuCl. When Fe salts alone are to be detd., the sepn. with CaCO_3 can be made so quickly that the oxidation is inappreciable. If Cu' or Cu'' salts are present, some Cu is usually pptd. with the Fe and the filtration is slow. The addition of NH_4Cl makes filtration more rapid.

E. W. BOUGHTON.

Fluoboric and fluosilicic acids in the qualitative analysis of sodium. F. C. MATHERS, C. O. STEWART, H. V. HOUSEMAN AND I. E. LEE. *J. Am. Chem. Soc.* **37**, 1515-7 (1915).—The filtrate contg. Na, K, NH_4 and Mg was evapd. to dryness and the NH_4 salts removed by ignition, part of the soln. tested for K, and the remainder for Na by adding an excess of fluoboric acid in 50% EtOH. The K was completely pptd. as KBF_4 , which was easily filtered. The Na may be pptd. in the filtrate with H_2SiF_6 . It is not necessary to remove Mg as with the pyroantimonate test. The test is well adapted for class work in beginning qual. analysis.

E. B. MILLARD.

Method for the determination of phosphorus pentoxide in limestones low in phosphoric acid content. F. HINDEN. *Z. anal. Chem.* **54**, 214-6 (1915).—To 25 g. of the powdered material and 100 cc. H_2O in a liter covered beaker, gradually add 120 cc. dil. HNO_3 (1:1) and heat to boiling. Filter and wash with hot H_2O . Heat the filtrate in a liter beaker to boiling; add NH_4OH (1:1) till slightly turbid. (If Al and Fe are not present in appreciable amts., add a few drops of FeCl_3 soln.) Add 0.5 g. of pure pptd. CaCO_3 , boil for 5 min. and let settle. Filter, wash with hot H_2O and dissolve ppt. on paper in 5-10 cc. of dil. HNO_3 (1:1); evap. soln. to dryness on the water bath, take up with 30-40 cc. of H_2O and a little HNO_3 , filter out SiO_2 and ppt. P_2O_5 in the filtrate by Woy's method (cf. *Z. öffent. Chem.* **3**, 321 (1897); *Analyst* **22**, 333 (1897); also Treadwell's "Lehrbuch der analytischen Chemie" 1907, Bd. 2, 330) with MoO_3 soln. The method was devised for the examn. of limestone for carbide factories. Results are reported on a number of samples by the above method and are shown to average 17.5% more P_2O_5 than the usual method gives when a 10 g. sample is employed. The main advantage of the method is the small vol. of soln. for pptn. (50-100 cc.), as against 5 to 10 times this vol. in the usual methods.

F. W. SMYTH.

The determination of sulfuric acid and of potassium, especially in potassium salts. I. W. VAUBEL. *Z. öffent. Chem.* **20**, 426-34 (1914).—A comprehensive detailed review of methods. II. The determination of sulfuric acid according to the barium and the benzidine methods and of potassium according to the perchlorate method. *Ibid* **21**, 1-6 (1915).—V. concludes that the detn. of H_2SO_4 by Ba pptn. in the presence of K is accompanied with large negative or positive errors, the chief ones being due to the simultaneous pptn. of K_2SO_4 or the solubility of some BaSO_4 . The detn. of K by the perchloric acid method does not give accurate results in the presence of H_2SO_4 . The pptn. of H_2SO_4 is best carried out by benzidine hydrochloride in the presence of K, while K in the presence of H_2SO_4 can be pptd. by sodium cobaltic nitrate and the ppt. titrated. In the direct detn. of K and Na results can only be obtained by the employment of benzidine pptn. for the H_2SO_4 and the $\text{Co}(\text{NO}_3)_2$ pptn. for the K. In cases where H_2SO_4 is to be detd. by Ba pptn. Na_2CO_3 or NaNO_3 is to be preferred to KNaCO_3 , KNO_3 or K_2CO_3 as a flux.

H. A. LEPPER.

A method for the determination of carbon dioxide in baking powder and carbonates. H. W. BRUBAKER. *J. Ind. Eng. Chem.* **7**, 432-3 (1915).—This simple rapid method is based on the liberation of CO_2 which displaces its own vol. of a satd. soln. NaCl and measurement of the vol. displaced. The method is fairly accurate. Details are given.

ISADOR MILLER.

Quantitative micro-analysis of organic substances according to Fritz Pregl. J. V. DUBSKY. *Chem. Ztg.* **38**, 505-6, 510-1 (1914).—D. describes in detail the micro-

methods developed under the supervision of Pregl for the elementary analysis of org. compds. *Detn. of N* by the micro-Dumas method: 2-7 mg. of material used; the combustion tube is 34 cm. long and 10 mm. in diam., and is drawn out 5 cm. with a diam. of 5 mm. at one end. The vol. of N is detd. in the micro-azotometer which can be read to 0.002-0.005 cc.; an empirical correction of +2% is made on account of capillarity of the 50% KOH soln. One filling suffices for 15 or more detns. The micro-Kjeldahl method may also be used for N. For the *detn. of C and H* 4-7 mg. of material are used; the combustion tube is 9-10 mm. in external diam. and 25 cm. long and is drawn out at one end for 10 mm. with 4 mm. diam. Granulated PbO_2 is used in addition to CuO , CuO -gauze, etc. The H_2O is absorbed and weighed in a tube 7 mm. in diam., with a 9 cm. layer of $CaCl_2$ of the fineness of millet seed and containing a packing of glass wool to prevent loss by "dusting." The CO_2 absorption tube (7 mm. in diam.) contains a 4 cm. layer of $CaCl_2$ and 6-7 wads of glass wool moistened with 50% KOH soln. Special directions are given for cleaning and charging this tube; one charge suffices for 2 detns.; $CaCl_2$ tube above will last for 10-15 detns. Each of these tubes is drawn out about 3.5 mm. at each end for making connections. The $CaCl_2$ may be regenerated by heating the tubes in a Cu block or by connecting one end to a vacuum pump and other end to a $CaCl_2$ tube with capillary opening. The $CaCl_2$ tube weighs about 3 g., the KOH- $CaCl_2$ tube about 5 g. S and halogens are detd. by Donau's methods (cf. *C. A.* 4, 1002; 6, 1417). It is stated that 1 mg. of substance suffices for detg. N; 1-2 mg. for C and H. Results for C, H, and N are reported for a number of org. compds. These show in most cases very good agreement with theory. (Cf. *Monatsh.* 23, 1(1902); *C. A.* 4, 3066; 6, 763). F. W. SMITHER.

EDGAR T. WHERRY.

Noteworthy crystals from Austria. ALOIS CATHERIN. *Neues Jahrb. Min. Geol.* 1915, I, 28-34; *Chem. Zentr.* 1915, I, 630.—The following crystals are described: A gypsum cryst. and a twin with (101) as the twinning plane which has grown from an ellipsoidal group of lenticular crystals from a sandpit at St. Agatha. A black tourmaline from Katsbach near Linz with lustrous prisms and dull terminal faces under a cover of stilbite. A pseudo-orthoclase (anorthoclase) from Reichensteim of the rare square-column type. White, lustrous plagioclase from the Wilheringer road, and also a twin according to the Carlsbad law, in which both individuals are twinned similarly according to the albite law. J. H. BOWER.

The previous condition of the silica in agate porphyries. R. E. LIESGANG. *Silikat-Z.* 2, 167-73(1914).—The previous hypothesis set forth by L. (*C. A.* 5, 3667) that the agates existing in porphyries were caused by the rhythmic pptn. of a pre-existing silicic acid gel, is applicable only to a part of the occurrences. In many others it is necessary to assume that the silicic acid was present in the sol. form, e. g., as water

glass. This is supported first by the occurrence of agates in Uruguay, etc., with the material deposited in horizontal strata under the influence of gravity, and also by the existence of numerous tubular ones which may have been formed in a manner similar to the "silica plants" from water glass and sol. Fe salts. C. S. KINNISON.

Brazilian monazite. A. L. GOTTSCHALK. *Chem. Eng.* 21, 169-70(1915); *Mining Engineering World* 42, 903-4(1915).—The following analysis of monazite sand was furnished by F. H. Lee of the Brazilian Geol. Service: P_2O_5 29.28, Ce_2O_3 31.28, La_2O_3 , etc., 30.88, SiO_2 1.40, ThO_2 6.49, loss on ignition 0.20, sum 99.53%. The mean ThO_2 content of the product regularly marketed from the only sources thus far found to be commercially payable, ranges from 5.75 to 7.1%. The general character and location of the Brazilian monazite deposits are given, also those of ZrO_2 .

L. W. RIGGS.

The formation of sodium carbonate and sodium sulfate in nature. A. LUCAS. *Cairo Sci. J.* 8, 185-8(1914).—Four possible explanations for the formation of Na_2CO_3 in nature are: (1) by the action of water containing CO_2 upon rocks containing Na_2SiO_3 or products of its alteration; (2) by the interaction of $NaCl$ with the carbonates or bicarbonates of Ca or Mg; (3) by the interaction of $CaCO_3$ with Na_2SO_4 ; and (4) by the reduction of Na_2SO_4 to Na_2S and the conversion of the latter to the carbonate by CO_2 . Na_2SO_4 may be produced by the action of $NaCl$ upon $CaSO_4$ or $MgSO_4$. Another method for the formation of both Na_2CO_3 and Na_2SO_4 is through the agency of zeolites. The zeolites are alteration products formed from the decomposition of other minerals—especially the feldspars—and consist of Al silicates united with an alkali or alkaline earth. The zeolites will exchange all their Na for an equivalent amt. of alkaline earth or even of heavy metals and are therefore suitable for water softening. By such an exchange with the sulfate or bicarbonate of the alkaline earths or heavy metals are $NaHCO_3$ and Na_2SO_4 formed. The presence of zeolitic material explains the formation of Na_2CO_3 in the cultivated lands. Such material is of widespread occurrence in both Upper and Lower Egypt.

R. L. SIBLEY.

The use of the microscope in mining engineering. F. W. APGAR. *Trans. Am. Inst. Mining Eng.* 47, 65-77(1914).—A discussion of the use of the petrographic microscope. Cuts are given showing: the mineralogic changes that may be found in a vein from the surface downward; rock alteration; changes in rock texture produced through differences in the rate of cooling, etc.

F. W. SMITHER.

The silver content of the lead ores of the East Alpine Triassic limestones. RICHARD CANAVAL. *Z. prakt. Geol.* 22, 157-63(1914).—A review of the literature pertaining to the Ag and Pb production of the region.

H. L. OLIN.

Geology of the Burro Mountains copper district, New Mexico. R. E. SOMERS. *Bull. Am. Inst. Mining Eng.* 1915, 957-96.—This region, in the s. w. part of the state, contains 2 classes of ore deposits: (1) quartz veins with Au and Ag, and (2) Cu deposits in fracture zones with a disseminated replacement of the walls. The Big Burros consist of a pre-Cambrian granite complex into which has been intruded a mass of quartz monzonite of post-Cretaceous age. The Cu occurs in 3 stages, (1) the upper oxidized zone from which most of the mineral has been leached but which still retains some azurite and malachite; (2) the enriched zone of chalcocite, 200-300 ft. thick, developed by replacement of primary pyrite, and the only one of commercial importance; (3) the primary zone of unaltered minerals. The district is comparatively undeveloped and prospecting will probably disclose new ores.

H. L. OLIN.

Geology and ore deposits of Copper Mountain and Kasaan Peninsula, Alaska. C. W. WRIGHT. U. S. Geol. Survey, *Professional Paper* 87, 110 pp.(1915).—Petrographic description and chem. analyses of the rocks of the district are given, and from

them the geologic history is deduced. W. describes a diopside-orthoclase containing over 73% orthoclase, a higher content than for any rock in Washington's tables, also a syenite porphyry containing phenocrysts of calcite which apparently crystd. directly from the magma. The ores are of the contact type, comprizing chalcopyrite, pyrrhotite, pyrite and magnetite. There is no enrichment. R. C. WELLS.

The copper pegmatite lode of Otjozonjati, German-Southwest Africa. H. WESTPHAL. *Z. prakt. Geol.* 22, 385-416(1914); *Chem. Zentr.* 1915, I, 271.—This Cu pegmatite is a new type. It is distinguished from the Telemarken-Monte Mullato type by a considerable rutile content and is to be classed as intermediate between the rutile veins of the Alps which have no Cu, and the quartz-Cu veins of the Butte, Mont., type. W. C. WHEELER.

The Gross-Fragant pyrite deposits. W. F. v. REITZENSTEIN. *Z. prakt. Geol.* 22, 197-212(1914).—R. describes in detail the petrography and geology of this ore zone, which consists of 2000 m. of micaceous schist, gneiss, carbonate rock and pyrite, underlying an intrusion of gneiss. The ores are Fe and Cu pyrite and magnetite, of varying structures. Their Cu content ranges from 7 to 10%, Fe, from 31 to 38%, and S from 33 to 42%. H. L. OLIN.

The geology and petrography of the South Norway pyrite deposits with special reference to their origin. OTTO FALKENBERG. Christiania. *Z. prakt. Geol.* 22, 105-54(1914).—F. describes in detail the pyrite-bearing rocks of the Norwegian Silurian, classifying them in the following zones: the Christiania region with alum shales containing small amts. of macroscopic pyrite but no workable deposits; the blue-quartz region of metamorphosed sandstones and igneous rocks; the Meldalen region lying in a great syncline 150 km. wide, which is the chief pyrite-bearing section; the west coast formations of diorite, gabbro, and granite; and the Söndfjord zone of conglomerate and sandstone several thousand m. in depth. With respect to the origin of the pyrites, he supports the views of Durocher, Kjerulf, and others, who consider them the products of metamorphosis of various minerals absorbed by intrusions of molten gabbro, and thinks that most of the Norwegian pyrites were formed in this way. H. L. OLIN.

The formation and distribution of residual iron ores. C. L. DAKE. *Bull. Am. Inst. Mining Eng.* 1915, 937-46.—Residual soils rich in Fe are produced both by weathering and by hydrothermal decay. In regions of heavy rainfall important accumulations may be formed by the decompn. of the relatively sol. limestones and basic igneous rocks with subsequent conc. of Fe, while in polar and arid regions only mechanical disintegration takes place. Laterites (mixts. of $\text{Fe}(\text{OH})_3$, $\text{Al}(\text{OH})_3$, and SiO_2), developed only from basic igneous rocks, are common in the tropics and are the most important residual ores. The action of steam on hot lava is probably a factor in the formation of Fe beds in volcanic regions. H. L. OLIN.

Potash in the Texas Permian. J. A. UDDEN. Texas Bureau Econ. Geol. *Bull. Univ. Texas* No. 17, 59 pp.(1915).—Two important features which this bulletin announces are the discovery of K-bearing salts in depth and the extent of the area in which this salt occurs. The K-bearing material is a solid and not a brine. One well at a depth of 875 to 925 feet contained 87.24% sol. material and of this 9.23% was "potash." Another well at a depth of 1700 feet contained 51.72% soluble material and of this 10.50% was "potash." Borings from two wells contained a bright salmon-red substance which upon analysis showed about 14% KCl and resembled carnallite. This occurred at a depth of 900 feet below the surface in a bed of rock salt, which overlies 3 other salt beds measuring jointly several hundred feet in thickness. There are several circumstances which suggest that an isolated basin existed in the region at the period when

the salts were deposited. Twenty-six samples taken from depths varying from 800 to 1700 feet showed potash content from 0.31 to 10.50%. The figure 0.44% seems to represent the average potash contents of the main salt beds in the region. One significant feature of the occurrence of the red K-bearing rock (carnallite?) is that it is found near or in the upper part of the principal salt beds exposed. This suggests that the deposition of K was preceded by a long period of progressive concn. of the seawater, at the end of which the point of satn. for K salts was reached, and these salts began to separate from the brine in the sea. This is the first time that such salts have been observed in association with the rock salt in the Permian red-beds. R. L. S.

Fissure coals of the western province. W. VERSFELD. *S. Afr. J. Sci.* 11, 165-68(1914).—The deposits of secondary coal in rocks not of contemporaneous age occur in divisions of Sutherland, Fraserburg, Lainesburg, Prince Albert, and Beaufort West, S. Africa. The fissures vary from 1 inch to 6 feet in width, in widely varying depths, and in direction from vertical to almost horizontal. The calorific value is high, ash sometimes as low as 0.20%, moisture 2 to 15% and the material is thus of anthracite quality. From the knowledge at hand it seems that the fissures were filled from above and that the mother deposit no longer exists. An attempt is being made at commercial development. W. C. WHEELER.

Contributions to Sardinian petrography. I. Rocks of Monte Ferru. H. S. WASHINGTON. Geophysical Lab., Washington. *Am. J. Sci.* 39, 513-29(1915); cf. *C. A.* 2, 1678, 3045; 8, 311, 482, 649, 1078.—Chem. analyses of these rocks by W. are shown in the table below. A = trachyte (I." 5. 2. 3); B = phonolite (I(II). 5. (6). 1,3). C = basalt ("III. 5. 3. 4"). D = analcite basalt (III. (5) 6. 2. 5). E = olivine nodule in analcite basalt. F = augite nodule in analcite basalt. Many other analyses are given or quoted.

Primary analcite of the Crownst volcanic. J. D. MACKENZIE. *Mass. Inst. Tech. Am. J. Sci.* 39, 571-4(1915); cf. *C. A.* 9, 582.—M. presents additional reasons in favor of his previous conclusions, with reference to the primary nature of the analcite of this locality, and against the suggestion that the analcite may have been originally leucite but had been converted to analcite by the agency of Na solns. L. W. R.

The Scottish oil shales. G. BURG. Berlin. *Z. prakt. Geol.* 22, 98-103(1914).—The Lothian oil shale group which forms a 900 m. division of the calciferous sandstone series of the Scottish Carboniferous, is made up of bituminous and marly shales, sandstones, limestones, and tuffs, together with some coals of poor quality. A soft blue shale known as "blaes" contains no oil but is rich in NH_3 and the light hydrocarbons. The raw oil content of the better shales is 135-200 l. per ton. The oil has a sp. gr. of 1.8-2.2, a S content of 1.5%, and yields on distn. 7% naphthalene, 29% illuminating oil, and 17% fuel oil, besides lubricants and paraffin. The production in 1910 was 273,000 ton of raw oil and 54,000 tons $(\text{NH}_4)_2\text{SO}_4$, valued at \$8,000,000. H. L. OLIN.

The value of certain criteria for the determination of the origin of foliated crystalline rocks. J. D. TRUEMAN. *J. Geology* 20, 228-58, 300-16(1912).—Foliated crystalline rocks are of 2 types: (1) those which received their foliation during consolidation from an igneous melt (primary gneisses), and (2) those in which foliation is a secondary structure. The typical texture of primary gneisses is intermediate between the igneous and the metamorphic types, but owing to the conditions of formation a crystalloblastic or even cataclastic texture may be superimposed on the original, and therefore texture as a means of identifying primary gneisses is of only limited application. It has been suggested that the presence of zircon be used for the identification of igneous or sedimentary origin. T. concludes that the presence of abundant minute zircons indicates that the original rock was either igneous or an arenaceous sediment; when grains are uniform in character, well crystd., and fresh an igneous rock seems likely; when well rounded and lacking in luster the original rock was probably sedimentary. Chem. analysis has frequently been used as a means of detg. the original igneous or sedimentary character of metamorphic rocks. Its use is based on the supposition that a rock as a whole undergoes no significant chem. change during development of schistosity. In some instances important chem. changes do take place. The case of the quartzite at Waterloo, Wis., is discussed. Here the zircon and ilmenite content of the schist is much greater than that of the quartzite. W. F. HUNT.

Metamorphic studies. C. K. LEITH AND W. J. MEAD. *J. Geology* 20, 353-61 (1912).—The succession of katamorphic and anamorphic changes constitutes a metamorphic cycle, and the recurrence of cycles constitutes great earth pulsations. The changes involved in the metamorphic cycle result in a permanent net loss of energy from the system in the form of heat. The incompleteness of the cycle as inferred from energy changes is also indicated by field evidence: (1) Completion of the cycle would involve reproduction of igneous rocks from sediments by sub-crustal fusion, but within the zone of observation this has been accomplished only on a small scale. (2) Certain salts split off from the cycle and remain in the ocean. (3) Segregation of CaO near the earth's surface as the result of its expulsion in the zone of anamorphism and its conc. in the zone of katamorphism occurs, the schists and gneisses containing a minimum of CaCO_3 or even Ca silicates. (4) MgO persists through the cycle to a much larger extent than CaO , and dolomites are therefore more abundant in the older and more highly metamorphosed terranes. (5) Al_2O_3 and SiO_2 are not only redistributing substances but by their combinations are the carriers of the energy involved in the changes. W. F. HUNT.

Ground-water resources of the Niles cone and adjacent areas, California. W. O. CLARK. U. S. Geol. Survey, *Water-Supply Paper* 345-H, 127-68(1915).—It is shown that the ground water in the vicinity of Niles has the same source as the surface waters, that is, it originates in the rain. A dense bed of impervious clay prevents loss of fresh water by seepage into California bay, as well as the encroachment of sea water in dry times from the bay toward the land. R. C. WELLS.

Note on the heating of an open hearth furnace by means of tar. A. GREINER. *Engineering* 99, 558(1915); *Iron Age* 95, 1072-3(1915); *Iron Trade Rev.* 56, 1017-8 (1915).—Notes on a 10-weeks expt. at the plant of the Cockerill Co. The tar is delivered to the sprayers (one only in each burner) with a regular feed and under a uniform pressure of 0.5 atm. It is sprayed by means of air compressed at about 3 atms. The hot air of combustion is admitted above the injector through the existing port, inclined at an angle of 45°. The av. consumption during the period was 293 lbs. (133 kg.) per ton of steel, including that required for lighting up and for heating during stoppages. With an uninterrupted run this av. falls to 253 lbs. (115 kg.) per ton. The av. wt. of the charges had to be diminished in order to avoid any deflection of the jet of flame issuing from the pulverizer towards the crown of the furnace. Several charges of 15 tons were successfully worked. The proportion of pig Fe found necessary in the charge rose to 28%. After 215 charges, producing 1986 tons of steel, the furnace was in an excellent working condition; the roof appeared even less damaged than after a similar campaign with coke-oven gas; only the chambers became encrusted. The bricks of the checker-work became covered with a carbonaceous substance. Some means will have to be devised to remedy this inconvenience. A new 25-ton furnace has been built and put into operation as a result of the above tests. A table is given showing results of expts. with producer gas, coke-oven gas, and tar. F. W. SMITHER.

The use of coal in blast furnace practice. FR. LANGE. *Stahl u. Eisen* 35, 265-8 (1915).—Anthracite coal, dried, finely powdered and introduced into the furnace through the tuyères, was found to greatly reduce the coke required. In some cases the saving is more than enough to offset the cost of drying and pulverizing. An intense heat is obtained in the hearth; this is particularly favorable when smelting for Fe-Si, Fe-Mn, and Fe-Cr, which require a high temp. It is also possible to treat high S ores

and obtain a low S-Fe because the slag can be run higher in CaO with the increased temp. Small furnaces are recommended for treating unbriquetted fine ores. More satisfactory results will be obtained with the old fashioned pipe stove because of the more even blast temp.

Flotation in gold metallurgy. W. B. BLYTH. *Aust. Inst. Min. Eng., Bull.* 16; *Met. Chem. Eng.* 13, 308 (1915).—It is only a question of time until flotation of Au ores will be generally practiced. A few plants for this process are already in successful operation. The method is especially valuable for the treatment of Cu-bearing gold ores since it is desirable to remove the Cu before cyanidation in order to decrease the amt. of cyanide consumed.

L. A. TOUZALIN.

Metallurgical practice in the Witwaters Rand District, South Africa. F. L. BOSQUI. *Bull. Am. Inst. Mining Eng.* 1915, 997-1033.—The ores of the Rand range from 4 1/2 to 9 dw. Au per ton. Before the introduction of cyaniding (1890) the av. recovery was about 60%. At present it attains a max. of 96%. The chief contributing factors were: slime treatment (1894); tube mills (1904); improvements in classification, cones, etc. (1907 to 1910); the vacuum slime filter (1909). In sorting, the belt is most generally used. For crushing, stamp mills are preferred. In the newest mills battery plates are dispensed with, amalgamation being used only after tube milling. In treating the

sand with KCN, the tendency is to use a weaker soln. than formerly. The "strong solns." of most mills range between 0.10 and 0.25%. Contact of 6 to 8 days is the av. period. Slimes are treated in Pachuca tanks. For pptn. Zn shavings wet down with PbOAc are used, 1 cu. ft. of same lying loosely being allowed per ton of soln. B. regards the Zn dust method as a decided advance. In cleaning up the Zn-Au slime the NaHSO₄ which is a by-product in the manuf. of nitroglycerin (about 30% available acid) is most commonly used. Both direct crucible smelting, and Pb smelting are used to obtain the bullion. E. WALLER.

Mill and cyanide plant of Chicksan Mines, Korea. C. W. DEWITT. *Bull. Am. Inst. Mining Eng.* 1915, 931-6; *Mining Press* 110, 731-2 (1915).—The ore is a quartz. The av. value is a little under \$7 per ton. The ore is passed through grizzlies, the oversize to Blake crushers, then to the stamps. Both inside and outside amalgamation is used. Then it passes to concentrating tables, the concentrates being shipped to U. S. The cyanide plant is in process of expansion. After desliming, the sands are treated for 7 hrs. in a leaching vat with 0.2% KCN. When that is run off, 0.10% KCN is run on, followed by at least 2 washes of H₂O. The vats are freshly charged every 4 days. The soln. is pptd. by Zn shavings. The Zn-Au slimes are treated 3 days with H₂SO₄, then dried, etc., and smelted. E. WALLER.

Reclaiming brass sweepings. A. W. LEMME. *Iron Age* 95, 946 (1915).—Sweepings collected at night are hand-picked for large pieces of metal. The tailings from 1 in. mesh screening of the sweepings are crushed. The product is jigged on 100-mesh for 30 min. with H₂O and hand-picked for Fe, then concd. on an Overstrom table. The concentrates are briquetted with stucco. Chem. control of products is used. H. V. MAIN.

Simple and efficient precipitant for copper from acid solutions. W. THOMPSON. *Mining Eng. World* 42, 810 (1915).—Based on lab. expts. with a carbonate ore, the use of FeS is recommended, as by it a lb. of Cu may be pptd. more cheaply from the leach soln. than by any other means under av. conditions. The process is suggested for the low grade oxide and carbonate ores and small deposits of similar ores that cannot be economically worked by present methods. The ores are leached with dil. H₂SO₄ and the pptn. effected according to the equation: $2\text{CuSO}_4 + \text{H}_2\text{SO}_4 + \text{FeS} \rightleftharpoons \text{Cu}_2\text{S} + \text{FeSO}_4 + 2\text{H}_2\text{SO}_4$. Scrap Fe is more expensive as a precipitant than FeS, a minimum of 1.5 lbs. being consumed for each lb. of Cu pptd. as cement Cu. F. W. SMITHER.

Reverberatory smelting practice of Nevada Consolidated Copper Co. R. R. H. POMEROY. *Bull. Am. Inst. Mining Eng.* 1915, 445-53.—Data are given of the performance of a reverberatory furnace for a period of 4 months, together with a description of the plant. P. gives the following as the vital points: *Factors affecting efficient combustion of the fuel* (Calif. crude oil): (1) The use of a burner to give a proper atomization of the oil so as to obtain a long, uniform flame without overheating any portion of the furnace. (2) Regulation of the draft so as to furnish the proper mixt. of gases for complete combustion in the furnace. *Factors affecting the operation of the furnace proper*: (1) Careful prepn. of the charge by adequate mixing of all ingredients before charging. (2) Addition of enough CaCO₃ rock, preferably coarse, to produce an active boiling in the furnace. (3) Maintaining a deep bath of molten mat to equalize and distribute the heat over the whole of the hearth. (4) Frequent skimming so as to carry only a thin layer of slag over the mat bath. (5) Operating the furnace for the best smelting conditions, ignoring the waste heat boilers as factors in the power supply. *Factors affecting the life of the furnace*. (1) The furnace roof set high over the hottest portion of the hearth. (2) Frequent fettling to protect the side walls. (3) Frequent charging and active charge mixts. to avoid floater and blanket formation requiring excessive firing. Diagrams, curves, tables, and analyses are given. F. W. SMITHER.

Metallic copper from an iron blast furnace. P. W. HEIKE. *Stahl u. Eisen* 35, 313-6(1915).—After blowing out an iron blast furnace some Cu was found under a furnace sow. The metal was found to contain some Pb. It is possible that the presence of Pb has prevented the Cu from dissolving in the Fe. The latter contained only 0.25% Cu.

CARLE R. HAYWARD.

The progress of zinc blende roasting, mechanically, since 1911. E. SCHÜTZ. *Metall u. Erz* 3, 109-18(1915).

CARLE R. HAYWARD.

The metallurgy of zinc. FRANZ JURETZKA. *Metall u. Erz* 3, 63-9, 94-102(1915).—The high price of Zn has caused considerable activity in devising methods for recovering the metal from waste products, for the treatment of complex ores and for improving standard processes. Several of these processes are outlined under: *wet concentration, leaching, and pyro-chemical processes*. Wet concn. has been successful in treating muffle residues from Pb-Zn-Ag ores. One such process is outlined. Galvanized Fe scrap is being treated by heating, the Zn being recovered as oxide, or by leaching with HCl. Some ores are given a chloridizing or sulfatizing roast and leached with H₂O. Zn has been recovered from slags by passing CO or oil into the molten material. Another process for treating slags is to melt them in a reverberatory furnace and stir in coke to reduce the Zn. The fumes are recovered in bag filters. Muffles form a large item in Zn smelting processes, partly due to the time (90 days) it takes to cure them. The time has been materially cut with apparently no bad effects on the product by blowing air through a perforated tube placed inside the muffle. By thus having a current of air both inside and outside the muffle, rapid drying is effected without causing cracks. In some cases the time required is only 24 hrs. An improved form of muffle furnace is described and illustrated. The muffles each take about 500 lbs. charge and operate with 86% recovery. An app. for treating Zn ores by mixing them with C and blowing air through the mixt. is also described. The construction is simple and the exptl. work has proved successful. The Zn may be recovered either as metal or oxide.

CARLE R. HAYWARD.

The mining and reduction of quicksilver ore at the Oceanic Mine, Cambria, Calif. C. A. HEBERLEIN. *Bull. Am. Inst. Mining Eng.* 1915, 497-504.—Owing to the demand for Hg due to the European war (price has risen from \$35 to about \$50 per flask of 75 lbs.) the low-grade ores of Calif. are being worked. The low-grade mud rock of the Oceanic Mine, near San Luis Obispo, varies from 6 to 8 lbs. of Hg per ton. The pay vein averages 20 ft. in width, and has its own local characteristics. The method of mining employed is described; cost is \$1 to \$2 per ton of ore. Wet ores are first concd. and then treated in the Scott furnace; but the dry ores are directly charged into the Scott furnace of the usual type. The ore is crushed at the mine to about 1½ in. diam. and delivered to plant by a bucket tramway. The wet ore is fed by a challenge feeder into 3½ ft. Huntington mill provided with 16 mesh screen. Without settling the under-size passes directly to a Deister table. The charge contains about 0.3% Hg, or 6 lbs. per ton, and the concentrates carry about 5% Hg. The extn. is about 80% and the conc. ratio 20:1. Cost is about 50 cents per ton. The conc. of the wet ore is successful at the Oceanic but more costly than direct furnace treatment. The concentrates are dried and then charged into the Scott furnace, but not into the retort, as this would prove too expensive. The furnace plant consists of a 50-ton Scott tile furnace, one brick condenser, and 3 wooden (redwood) condensers. In the last 2 yrs.' operations many improvements have been made, among which are the automatic sealing of the charge; the reinforcing of the tiles; and radical changes in the firing and the system of condensing. About 110 flasks per month is the av. yield and the av. extn. = 90.8%. With a recovery of 91%, or 5.91 lbs. of Hg per ton, at 50 cents per lb., the value recovered would

be \$2.95 per ton at a total cost of \$1.50. Detailed descriptions with cuts are given.

F. W. SMITHER.

Recovery of mercury from residues of amalgamated cobalt ores. E. B. THORNHILL. *Can. Mining Inst. Bull.* 36, 263-8(1915).—Much Hg, chiefly as HgS , is retained in the amalgamation residues of cobalt high-grade Ag ores and concentrates in strong cyanide soln. The cake of residue from the cyanide soln., washed free of Ag with H_2O , is immersed in the filter basket in soln. of alk. Na_2S , which is slowly drawn through the cake till the effluent shows only a trace of Hg. The filtrate is then agitated with metallic Al, the ppt. of Hg allowed to settle, and the clear soln. decanted. The ppt. is washed with H_2O , the fluid Hg sepd. by raking, and the powdered remainder is retorted to recover Hg in the usual manner. A soln. of 4% Na_2S and 1% NaOH gives best results. The Al used is a waste product from Al casting foundries. One ton of soln. is used per ton of residue.

R. B. DOLE.

The reduction of manganese in the blast furnace. H. THALER. *Oesterr. Z. Berg-Hüttenw.* 62, 621-8(1914).—A comprehensive investigation which T. summarizes as follows: (1) The reduction can be done directly or indirectly. (2) The fuel consumption increases with rising % of Mn. (3) The extrn. rises with increasing Mn content of the Fe and purity of ore. (4) Hot running is favorable for Mn reduction. (5) The loss of Mn by slagging decreases with rising Mn content of Fe. (6) The basicity of the slag must approach 0.8-1.0. (7) The Mn content of the slag ranges from 8 to 10%. (8) The relation of Mn to Si in the charge must not exceed a certain limit or reduction of SiO_2 takes place. (11) The loss of Mn by volatilization amounts to 7-8% in a 20% spiegel.

E. J. ERICSON.

Titanium and titaniferous ores. PAUL H. BERGGREEN. Sibley Coll. *Chem. Eng.* 21, 168-9(1915).—B. gives a review of various researches on the reduction of these ores and on the effect of the presence of Ti in Fe and steel. Large future possibilities of Ti-Fe ores are suggested.

L. W. RIGGS.

Recent progress in flotation. O. C. RALSTON AND F. CAMERON. *Eng. Mining J.* 99, 937-40(1915).

E. J. C.

Metallurgical treatment of the low-grade and complex ores of Utah. D. A. LYON, et al. Dept. Interior, Bur. Mines, *Tech. Paper* 90, 39 pp.—A preliminary report under the captions: (a) review of mining in Utah (Au, Ag, Pb, Cu, Zn); (b) situation and extent of the low-grade ores; (c) examination of the mining districts; (d) chemical characteristics of the Utah ores (analyses of 60 samples reported); (e) types of ores analyzed: (1) Cu carbonate ores. (2) Oxidized ores carrying PbCO_3 and Ag. Most of the ores contain over 50% of insol. matter, but the amt. of sol. Fe and CaO presents some difficulties to the application of hydrometallurgical processes. (3) Oxidized ores carrying small amts. of Cu and Pb as carbonates and also Au and Ag; most of these ores are siliceous, but some of them are high in Fe and CaO and might be classed as basic. (4) Oxidized ores with Zn as the chief constituent; and carrying occasionally Au and Ag. Most of these ores are too low in Zn for the smelters, and the oxidized Zn minerals present frustrate attempts to recover the Au and Ag alone. Zn is too high for smelting in a Pb or Cu blast furnace. (5) Oxidized ores with Zn and Pb as the 2 chief valuable constituents, and occasionally carrying some Ag and Au. (6) Oxidized ore containing Zn, Pb, Cu, Au, and Ag. (7) Any of the above groups only partly oxidized. (8) Complex sulfides of Zn, Pb, Cu and Fe carrying Ag and Au. (f) Metallurgical treatment of the ores: no commercially successful process is known whereby the valuable minerals may be concd. out of the low-grade oxidized ores. Hydrometallurgical processes offer most promise. None of the concentrating processes in use effect as close a sepn. of the Zn and Pb in complex sulfide ores as is desirable. Under chloridizing

processes the Holt-Dern and the Knight-Christensen are briefly described and their operation at Park City and Silver City discussed. (g) Processes having a possible application to Utah ores: a brief discussion of processes, e. g., the Murex, sulfidizing and flotation, electrostatic sepn., chloridizing and leaching, Mosher-Ludlow process, Slater process, igneous conc., leaching with $(\text{NH}_4)_2\text{CO}_3$, leaching with acid and electrolytic pptn. of Zn, bisulfite process, etc. (h) Raw materials in Utah for use as reagents: NaCl and Na_2SO_4 (from which Na_2CO_3 , HCl, HClO_4 , FeCl_3 , etc., could be produced); Fe ore suitable for the production of sponge Fe, etc. (i) Allied problems, cheap power, fuel, utilization of by-products, etc. F. W. SMITHER.

Hall process for desulfurizing ores. ALFRED W. G. WILSON. *Summary Rept. Mines Branch, Canada Dept. Mines* 1913, 27-30.—The process consists in subjecting the crushed ore to the direct action of a non-oxidizing blow pipe flame and steam, keeping the ore within a temp. range of 700-925°. Under these conditions free S distills off with very little SO_2 , SO_3 , or H_2S . When conducted in multiple hearth furnaces 100 to 125 lbs. of ore per sq. ft. hearth area may be treated per day, leaving a cinder with less than 1% S. S is extd. from the fumes by washing or it may be pptd. electrically by the Cottrell method. The product is from 98% to 99.5% pure.

H. L. OLIN.

Clarifying water from wet concentration of ore. G. NICOLAI. *Mettall. u. Erz* 3, 135-40, 155-62 (1915).—Filtering is unsatisfactory for this purpose. The best results are obtained by adding alum but economic reasons may make the use of some other inorganic substance advisable. MgCl_2 or H_2SO_4 solns. or other salt solns. are satisfactory. CARLE R. HAYWARD.

A new method for determining the gases in iron. P. GOERRENS AND J. PAQUET. *Ferrum* 12, 57-64, 73-81 (1915).—About 3 g. of the metal are heated in a MgO crucible with 3 g. Sb and 3 g. Sn under a reduced pressure of 0.003 mm. at 1100° until no more gases are evolved. The CO_2 , CO, H and N are then detd. by the usual methods of gas analysis, the entire analysis taking about 3 hrs. In the samples tested by this method there was obtained 0.002 to 0.02% CO_2 , 0.0015 to 0.10% CO, 0.002 to 0.004% H and 0.0000 to 0.0141% N, the values for the last gas being unreliable. In a badly deoxidized elec. steel 10 times as much gas was obtained as in a carefully prepared steel of the same character and it is shown, by means of curves, that the gas content gives a very good means of detg. to what extent the material has been refined. W. T. H.

The importance of annealing steel castings. P. OBERHOFFER. *Stahl u. Eisen* 35, 93-102, 212-6 (1915).—The paper gives tabulated results of mechanical tests on annealed and unannealed specimens together with photomicrographs of structures, all of which show the importance of annealing. The results supplement former papers by O. (cf. C. A. 6, 3083; 7, 3100; 8, 49). CARLE R. HAYWARD.

A comparative study of simple and repeated shock tests and rotary and alternate bending tests. M. NUSBAUMER. *Rev. metal.* 11, I, 1133-90 (1914).—Numerous samples of C-steel and steel alloys were subjected to twisting strains, repeated shock and alternate bending tests with the following results: In C-steels the resistance to these tests is proportional to the content of C, when this is less than 0.25-0.30%. Ni-steels are generally more resistant than C-steels to repeated shock or alternate bending but not to twisting strains. Steels of high Ni content are not superior to mild C-steel in these respects. Ni-Cr steels are more resistant than Ni-steel to repeated shock and twisting. In the Ni-Cr steel series, it is always the very soft steel which shows the max. resistance. Tempering considerably increases the resistance to alternate bending tests, while annealing has the directly opposite effect. Tempering diminishes the resistance to repeated shocks. With C-steels and low content Ni-steels, tempering

followed by annealing raises the resistance to repeated shocks, while with Ni-Cr steels this resistance is diminished. Tempering not followed by annealing increases the resistance to repeated shock in the case of mild C-steel and especially of steels of low Ni content, but diminishes their resistance to alternate bending. Ni-Cr steels by this treatment are more resistant both to repeated shock and alternate bending tests. Whatever the kind of repeated tests a metal is subjected to, it always breaks by progressive fissuration. Numerous photographs, tables and curves are given. L. T. F.

Tungsten projectiles. R. VASSELIN. *Rev. d'artillerie* 83, 343-50; *Rev. metal.* 11, II, 769(1914).—The obvious advantages (d., hardness, tenacity) of W are pointed out. Owing to the fact that the annual production of W is only 2-3000 tons, however, its immediate employment in the manuf. of projectiles is unlikely. L. T. F.

The chemical and mechanical relation of iron, cobalt and carbon. J. O. ARNOLD AND A. A. READ. *Engineering* 99, 362-4(1915); cf. *C. A.* 9, 1295.—Correction of page number. E. J. C.

Brit., 736, Jan. 10, 1914. LÖTBAND-GES. and J. KREISSIG (NÉE ECKRICH). **Soldering wires**, or the like, end to end, by enclosing the joint in a combustible tissue, such as hemp, cotton, fleece, cellulose, paper, etc., coated with pulverized solder mixed with flux and satd. with a heat-producing agent, such as a hydrocarbon or other chem. compd. or mechanical mixt., which is ignited to effect the soldering. The heat-producing agent may be mixed with the solder.

Brit., 902, Jan. 13, 1914. J. ABT. **A fluxing composition for brazing cast Fe to cast Fe, rod Fe, or cast steel**, consists of a plastic comp. or paste formed by mixing powdered steel or Fe, borax, an oil not containing resin or acid, such as coconut oil, paraffin oil, or vaseline, and ethylated spirits, preferably in the proportion of 60 parts of steel, 20 of borax, and 10 each of oil and spirits. The comp. may be restored to its plastic condition, if it hardens after keeping, by the addition of a small quantity of methylated spirits. In applying the compn., the articles are cleaned by a stiff wire brush and H_2O , and the compn. then applied and the articles clamped together. The joint is surrounded by borax and the articles heated in a furnace or charcoal fire or blue burner. The joint is sprayed with spelter and then covered with curved sheet Fe to retain the heat. Borax is then applied to promote free fusion. The article is removed after cooling.

Brit., 908, Jan. 13, 1914. T. V. HUGHES. **In annealing and coating metals or metal articles**, the heating is effected in an atm. of inert gases satd. with the vapor of the metal or alloy under treatment or of the coating metal or alloy, or both. The inert gas is passed, on its way to the heat-treatment chamber, through heated passages containing scraps of the desired metal mixed or not with refractory or other material, and scraps of the metal may also be placed at or near the inlet to the chamber; or

the articles to be treated may be surrounded by or placed in spaces having partitions made of sheets or netting composed of or coated with the desired metal. The scrap metal may be remelted and granulated from time to time for re-use by pouring the molten metal into a liquid or by pounding or shaking it at the temp. of crystn.

Brit., 922, Jan. 13, 1914. H. KÖPPERS and AKT.-GES. PEINER WALZWERK. The solubility of **phosphate slag** in citric acid is increased by stirring in silicious material before the slag solidifies. Slag from the converter is run into trucks, and about 500-600 kg. of sand are added to 7000 kg. of slag. A crust is allowed to form, and then stirrers are plunged through this crust to incorporate the sand with the slag.

Brit., 933, Jan. 13, 1914. W. A. HILLS. In recovering tin, zinc, or lead from scrap, the coating metal is volatilized, and the Fe is melted in 1 operation in a neutral or reducing atm., an elec. or surface-combustion furnace preferably being employed. The vapors may be condensed before or after oxidation, and preferably a water spray condenser comprizing a vertical wheel rotating in a closed tank is used; or the vapors may be forced into H_2O by means of an injector, or centrifugal machines may be used. If acid or alkali be added to the H_2O , the metals may be recovered in the form of chlorides, sulfates, stannates, zincates, etc. The molten Fe is refined with fluxes in the ordinary way, and any Sn, etc., that enters the slag may be recovered.

Brit., 1,368, Jan. 17, 1914. A. H. HIGGINS and MINERALS SEPARATION, LTD. A process for the selective separation of different constituents of an ore by flotation consists in the sep. treatment of products containing particles of substantially uniform size or containing particles having substantially the same rate of fall in liquid. The factors of differential gaseous attachment and of differential falling power in liquid are thereby utilized, and concentrates relatively high in certain constituents and residues relatively high in others are obtained. The sized or classified products may be treated by the process described in 16,141, 1913, or in the app. described in 21,650, 1913 (C. A. 9, 782). The frothing-agent used is preferably partly sol. in H_2O , such as eucalyptus oil, and is present in very small quantity, more being added during the treatment if required. Acids, alkalies, or sol. salts may be present. Cf. C. A. 8, 1562.

Ger., 279,989, May 12, 1910. ELEKTROSTAHL, G. M. B. H. A process of imparting acid properties to steel, in a basic elec. furnace, consisting in bringing the steel into contact, in the basic elec. furnace, with silicious materials containing no oxides of the heavy metals, as, *e. g.*, mixts. of SiO_2 or Al silicate with C, so that these materials form Si compds. with the steel as a result of the gradual action, in the heat, on the steel bath, such Si compds. dissolving in the steel. SiC may be added, if necessary. Briquet-like material may also be added to the steel in the furnace, *e. g.*, material composed of Fe, C, SiO_2 , or fire brick, or their mixts., together with SiC.

Ger., 280,204, Sept. 14, 1913. ERHARD & SÖHNE. Welding furnace with metal bath heating.

Ger., 280,414, Dec. 2, 1913. K. ALBERT, CHEM. FABRIK and O. SCHLEIMMER. Mfg. cast iron or steel from galvanized Fe scrap, by melting the scrap down in a highly heated Fe bath containing C, whereby all the Zn is eliminated. The product is worked further, in the known manner, to cast Fe or cast steel. The ZnO, most of which is volatilized immediately, and the balance of which is driven off with the flue gases, is recovered by filtration. The Fe obtained from such scrap is free from S and O, as the Zn removes both S and O. When used in connection with the Siemens-Martin furnace, this process necessitates the provision of exhaust channels.

C. A. ROUILLER.

Constitution of the glycerophosphoric acid in lecithin. O. BAILLY. *Compt. rend.* 160, 395-8(1915).—Willstätter and Ludecke (*Ber.* 37, 3754) have shown the presence of β -glycerophosphates in lecithin and Fourneau and Piettre (*C. A.* 7, 803) have succeeded in isolating 2 Ca glycerophosphates from the alcoholysis products of lecithin, without characterizing these compds. On hydrolyzing 100 g. lecithin from egg yolk, B. obtained a mixt. of Ca α - and β -glycerophosphates, which were readily sep'd. and identified by Grimbert and B.'s methods (*C. A.* 9, 1309). Egg lecithin therefore appears to be a mixt. of α -lecithin, $\text{HOC}_2\text{H}_4\text{NMe}_3\cdot\text{O}\cdot\text{P}\cdot\text{O}(\text{OH})\cdot\text{O}\cdot\text{CH}_2\text{CH}(\text{OR})\text{CH}_2\text{OR}$ (R = oleyl, stearyl or other acyl radical), and β -lecithin, $\text{HOC}_2\text{H}_4\text{NMe}_3\cdot\text{O}\cdot\text{P}\cdot\text{O}(\text{OH})\cdot\text{O}\cdot\text{CH}(\text{CH}_2\text{OR})_2$. Also in *J. pharm. chim.* 11, 204-13(1915). L. E. W.

Benzofulvanol and benzofulvene. V. GRIGNARD AND C. COURTOT. *Compt. rend.* 160, 500-4(1915); cf. C. A. 8, 3436.—Mg indene bromide in anhydrous Et_2O was heated and mechanically shaken (cf. C. A. 8, 2) with $(\text{CH}_2\text{O})_3$ for about 5 hrs. in H. The Et_2O soln. was then poured on ice, treated with NH_4Cl and NH_4OH to dissolve Mg salts, washed with H_2O , dried by means of Na_2SO_4 , and evap'd. (at temp. not $>50^\circ$). The residue, fractionated *in vacuo*, gave a 70% yield of α -benzofulvanol,

$\text{CH}:\text{CH}:\text{CH}:\text{CH}:\text{C}:\text{C}:\text{CH}(\text{CH}_2\text{OH})\cdot\text{CH}:\text{CH}(\text{A})$, $b_{10} 134^\circ$, possessing an odor of roses.

When passed over pure Al, heated to 250° under 15-20 mm., (A) is dehydrated and converted into benzofulvene (B), $\text{CH}:\text{CH}:\text{CH}:\text{CH}:\text{C}:\text{C}:\text{C}:(\text{CH}_3)\cdot\text{CH}:\text{CH}$, greenish

yellow leaflets, m. 37° , extremely unstable and polymerizing readily when kept *in vacuo* over H_2SO_4 or in sealed tubes, and forming the polymer, $(\text{C}_{10}\text{H}_8)_n$, vitreous yellow mass softening appreciably at 180° , but without definite m. p. (B) absorbs O and Br very readily. Other dehydrating agents such as ZnCl_2 , H_2SO_4 and KHSO_4 act upon (A), giving rise to resins. By treating Mg halide derivs. of fluorene and cyclopentadiene with aldehydes and ketones, G. and C. obtained fulvanols and dibenzofulvanol derivs. which yielded colored fulvenes and dibenzofulvenes upon dehydration.

LOUIS E. WISK.

Theory of oscillation of the indene double linkage. C. COURTOT. *Compt. rend.* 160, 523-6(1915); cf. preceding abst.—Thiele and Bühner (*Ann.* 347, 249) found that the reaction between PhCH_2Cl and indene in the presence of alkalis led to the formation of the benzy lindene (A), m. 34° , also obtained by the reducing action of Hg-Al upon

benzylideneindene. To account for the non-formation of 2 isomeric (α and γ) benzylindenes, T. and B. formulated their "indene double linkage oscillation" hypothesis, expressed schematically as follows:

Repeating T. and B.'s work, but carrying out the reaction between PhCH_2Cl and indene, by the use of a Mg indene halide, instead of alkali, C. obtained a liquid benzylidene (*B*), b_{14} 175–77°, readily converted into (*A*) by the action of alcoholic KOH. (*A*) adds 2 Br atoms, the dibromide losing HBr spontaneously with the formation of T.'s benzylideneindene. (*B*), on the other hand, yields a yellow dibromide which loses very little HBr and which forms resins on attempted debromination with $\text{C}_6\text{H}_5\text{N}$. It is evident that (*A*) is the γ -benzylidene and that (*B*) is the less stable α -isomer. The "indene oscillation hypothesis" is therefore untenable. C. cites other examples of indene isomerism. Ph_2CHBr acting upon a Mg indene halide yields α -benzhydrylindene, colorless, m. 161°, readily converted into the γ -isomer, m. 115–6°, also obtained by hydrogenation of diphenylbenzofulvene.

LOUIS E. WISE.

Crystalline calcium-theobromine. LOUIS ROUSSEAU. *Compt. rend.* 160, 363–5 (1915).—Calcium-theobromine, $(\text{C}_7\text{H}_7\text{O}_2\text{N}_4)_2\text{Ca}\cdot 9\text{H}_2\text{O}$ (*A*), radiating clusters of fine needles, was formed by treating 1 mol. $\text{Ca}(\text{OH})_2$ with 2 mols. theobromine in CO_2 -free H_2O . Very dil. acids acting upon (*A*) yield colloidal theobromine. This reaction may account for the intensity of the diuresis caused by (*A*), which is probably converted into colloidal theobromine by the gastric juice.

LOUIS E. WISE.

Catalytic hydrogenation of liquids under the influence of common metals at moderate temperatures and pressures. IV. Reduction of aliphatic compounds with ethylenic linkings. ANDRÉ BROCHET AND MAURICE BAUER. *Bull. soc. chim.* 17, 50–5 (1915); cf. *C. A.* 8, 3180.—In the following expts. the compds., usually in appropriate solvents, were mixed with relatively large amts. of active Ni (10–20 g. per 100 g. of compd.) and shaken in a H atm. under an initial pressure of about 15 kg. per sq. cm., at temps. ranging from 13° to 100°, depending on the nature of the substance and solvent used. During the course of the hydrogenation, the pressure frequently fell to 5–8 kg. per sq. cm. and in most expts. a fresh charge of H was required to complete the reduction. By these means $\text{CH}_2\cdot\text{CH}(\text{CH}_3)_2$ in EtOH was completely reduced at room temp. to $\text{Me}(\text{CH}_2)_3\text{Me}$, b_{724} 122–4°. $\text{PhCH}\cdot\text{CHCO}_2\text{H}$ (100 g. in 200 g. $\text{C}_6\text{H}_{11}\text{OH}$) was readily converted into $\text{Ph}(\text{CH}_2)_2\text{CO}_2\text{H}$ at 100° in about 1.25 hrs. This reduction proceeds more slowly when carried out in EtOH at temps. not exceeding 40°. In both cases, however, the solns. are contaminated by Ni salts. This difficulty was obviated by using $\text{PhCH}\cdot\text{CHCO}_2\text{Na}$ in H_2O , the reaction carried out at 13–21° going to completion in about 1 hr. and the alkalinity of the soln. apparently in no way affecting the activity of the Ni. Similarly $\text{PhCH}\cdot\text{CHCO}_2\text{Me}$ in MeOH was reduced to $\text{Ph}(\text{CH}_2)_2\text{CO}_2\text{Me}$, $b.$ 228–30°, and 3,4- $\text{CH}_2\text{O}_2\text{C}_6\text{H}_4\text{CH}\cdot\text{CHCO}_2\text{Na}$ in H_2O formed 3,4- $\text{CH}_2\text{O}_2\text{C}_6\text{H}_4(\text{CH}_2)_2\text{CO}_2\text{H}$ (?), b_{11} 171–2°. At 60–80°, anethole, without use of solvent, is converted into 4-MeOC₆H₄Pr, b_{78} 209–11°, which suffers no further reduction even at 190°. Eugenol, on the other hand, is reduced to dihydroeugenol (*A*), b_{718} 245–7°, which on further reduction at 200° yields octohydroeugenol, 3,4-MeO-(HO)C₆H₃Pr; phenylurethan, microcrystals, m. 272° (cf. Madinaveitia and Blanco, *Soc. espanola fis. chim.* 10, 381 (1913)). Safrole, on reduction, yields only dihydrosafrole, b_{781} 228–30°, even when the temp. is raised to 200°. Isoeugenol, when hydrogenated in EtOH at 15–22°, yields (*A*). V. Reduction under atmospheric pressure of aliphatic

compounds containing the ethylenic linking. With ANDRÉ CABARET. *Ibid* 55-9.—In these expts., H gas was bubbled through mechanically shaken solns. of unsatd. compds. containing suspensions of active Ni. Under these conditions, 1-octene, PhCH:CHCO₂H, its Na salt and Et ester, and 3,4-CH₂O₂C₆H₄CH:CHCO₂Na, may all be slowly but completely reduced to the corresponding satd. compds. The rate of hydrogenation of C₂H₅OH varied greatly in different expts., the catalyst apparently being poisoned during the course of the reaction. C₂H₅NCS suffered no reduction whatsoever, while isosafrole was rapidly and completely reduced to dihydrosafrole and anethole was more slowly converted into 4-MeOC₆H₄Pr. Unsatd. ketones could be converted into the corresponding satd. ketones by this method, whereas the use of H under pressure may cause reduction of the CO group. 30 g. 3,4-CH₂O₂C₆H₄CH:CHAc in 200 cc. EtOH in the presence of 20 g. active Ni were completely hydrogenated in 25 min. at 65-70°.

LOUIS E. WISE.

Action of acetic anhydride upon morphine alkaloids. M. TIFFENEAU. *Bull. soc. chim.* 17, 66-77(1915).—T. gives a review of the work of previous investigators in this field. The morphine alkaloids may be grouped into 3 classes according to their behavior towards Ac₂O. Morphothebaine, apocodeine and apomorphine (I) (Pschorr's

formula) and its derivs. all suffer fission between the 9-C atom of the phenanthrene nucleus and the adjacent N atom (with the formation of an amide, type III). Assuming that an unstable, intermediate acetylation product of type (II) is formed, which passes into (III), the fission may be considered a typical tertiary benzylamine reaction, analogous to the reaction: C₆H₄CH₂CH₂NMe.CH₃ + Ac₂O → AcO-

CH₂C₆H₄(CH₂)₂NMeAc (cf. C. A. 8, 1567). A 2nd class of alkaloids to which belong thebaine, codeinone and pseudocodeinone on treatment with Ac₂O undergoes a double rupture ("C and N fission"). As an example: thebaine (IV) forms thebayl acetate

and $\text{AcO}(\text{CH}_2)_2\text{NHMe}$. A 3rd class, which includes morphine, phenyldihydrothebaine (A), thebainone (V) (enol form), and codeine, suffers no rupture under the influence of Ac_2O , but simply yields the corresponding acetates. T. believes that the O bridge in (IV), which is lacking in (A), and (V) renders (IV) very much more sensitive to Ac_2O action. The typical benzylamine reaction to which the apomorphine alkaloids respond may be considered additional evidence in favor of Pschorr and Knorr's constitutional formulas (at least as far as the N-linking is concerned) and serve to reject such hypotheses as those of Gadamer (C. A. 8, 2875) who believes that the N in the morphine alkaloids is more probably linked to the 8-C atom of the phenanthrene nucleus.

LOUIS E. WISE.

Action of magnesium on halogen-substituted aromatic acids. YU. ZAL'KIND AND A. A. SHMIDT. *J. Russ. Phys. Chem. Soc.* 46, 681-7 (1914).—The previous work on this subject (C. A. 8, 3187) concerned compds. in which both the Br and the CO_2H were in the side chain. Extending the investigation to substances having either one or both of these substituents in the ring, the following regularities were established: Substances with both the Br and the CO_2H in the ring, as a rule, do not react with Mg (cf. Meyer and Toegel, *Ann.* 347, 71), and when the reaction is forced by prolonged warming with Mg activated with I the result is not formation of compds. of the Grignard type, but a sapon. of the ester group. The removal of the CO_2H alone to the side chain also has comparatively little effect on the mobility of the Br. But when the Br alone is in the side chain the reaction is greatly facilitated. Even then, however, the *p*-derivs. (e. g., *p*- $\text{CH}_2\text{BrC}_6\text{H}_4\text{CO}_2\text{Et}$) are almost inactive, only the *o*- and the *m*-derivs. reacting with Mg. The reaction in this case is similar to that of the β -halogen-substituted esters previously examd., more than 1 mol. of ester entering into reaction with formation of esters of dibasic acids. Thus in the reaction of *o*- $\text{CH}_2\text{BrC}_6\text{H}_4\text{CO}_2\text{Et}$ (a) with activated Mg 3 mols. of it condense to form the *hydroxy acid*, *o*- $\text{MeC}_6\text{H}_4\text{C}(\text{OH})(\text{CH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H})_2$ (amorphous *silver salt*; *acetate*), and the *m*-ester corresponding to (a) gives the corresponding *m*-acid, amorphous, becomes yellowish 250° , decomps. 280° (*silver salt*; *acetate*), gives upon oxidation *m*- $\text{MeC}_6\text{H}_4\text{COCH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ and *m*- $\text{C}_6\text{H}_4(\text{CH}_2\text{OH})\text{CO}_2\text{H}$. The Me ester corresponding to (a) did not react with Mg.

H. M. GORDIN.

Action of magnesium on the esters of bromosuccinic acid. YU. S. ZAL'KIND. *J. Russ. Phys. Chem. Soc.* 46, 688-92 (1914).—With a view to examg. the action of Grignard's reagent on the halogen-substituted esters of dibasic acids, expts. were made with Me and Et monobromosuccinates. It was found that the Me ester reacts less readily than the Et ester, the former requiring activated Mg, while the latter requires only a small crystal of I. Both esters yielded the corresponding esters of fumaric acid, showing elimination of HBr, together with the 2 isomeric esters of butanetetracarboxylic acid, showing that the reaction partly resembles that of Wurtz-Fittig, 1 mol. of $\text{RCO}_2\text{CH}(\text{MgBr})\text{CH}_2\text{CO}_2\text{R}$ reacting with 1 mol. of $\text{RCO}_2\text{CHBrCH}_2\text{CO}_2\text{R}$ with formation of MgBr_2 . In the case of Et bromosuccinate there also was a condensation of 3 mols. of the ester with formation of the ester of a *pentabasic acid*, $\text{EtO}_3\text{C}-\text{CH}_2\text{CH}(\text{CO}_2\text{Et})\text{C}(\text{OH})(\text{CH}_2\text{CH}_2\text{CO}_2\text{Et})\text{CH}(\text{CH}_2\text{CO}_2\text{Et})\text{CO}_2\text{Et}$, m. 257° ; *silver salt*.

H. M. GORDIN.

Saponification of esters with activated magnesium and the etherate of magnesium iodide. YU. ZAL'KIND. *J. Russ. Phys. Chem. Soc.* 46, 692-7 (1914).—Observation showed that when Mg activated according to Bayer or simply Mg mixed with a little I is used in Grignard's reaction with some esters there is, along with the formation of compds. of the Grignard type, partial sapon., resulting in the production of the acids underlying these esters. In order to exam. the extent of sapon., the yield in acids and its relation to the conditions of the reaction were examd., using BzOEt and the es-

ters of *o*- and *m*- $\text{BrC}_6\text{H}_4\text{CO}_2\text{H}$. The conclusions arrived at are as follows: In no case is the sapon. complete. This may be due either to the existence of a limiting state of equil., or to the reacting mass becoming so thick that proper interpenetration of the interacting substances is impeded. The latter cause would explain why the acid yield is independent of the amt. of MgI_2 etherate used. Mg alone causes no sapon., but when both Mg and I are present sapon. takes place, no matter whether we use the ready-made etherate or activated Mg or simply a mixt. of Mg and powdered I. The extent of sapon. is increased by increasing the amt. of activated Mg, by raising the temp. of the reaction, or by lengthening the time of heating. If only the required amt. of activated Mg is used, there is no resinification, and the reaction is a simple sapon. without the formation of any new substances. With BzOEt , *e. g.*, the reaction is either: $\text{BzOEt} + \text{MgI}_2 = \text{BzOMgI} + \text{EtI}$, or $\text{BzOEt} + \text{BzOMgI} = (\text{BzO})_2\text{Mg} + \text{EtI}$. With an excess of Mg there is considerable resinification, and the reaction is more complicated, the EtI produced interacting with the Mg, giving EtMgI which reacts with more EtI to form MgI_2 and C_2H_{10} . The formation of the latter accounts for the (slight) pressure observed when the reaction is carried out in a sealed tube. H. M. G.

Reaction of dibromomethyl ether with benzene in presence of aluminium bromide. I. L. RABTZEVICh-ZUBKOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 698-704 (1914).—In many respects $(\text{CH}_2\text{Br})_2\text{O}$ (a) behaves like acid chlorides (is decompd. by H_2O , reacts with alcs., etc.). Since the latter interact with C_6H_6 in presence of AlBr_3 to form ketones, (a) was expected to yield under these conditions some or all of the isomeric compds., $\text{C}_6\text{H}_4\text{CH}_2\text{OCH}_3$. Expts. proved, however, that neither in CS_2 nor in C_6H_6

are such compds. produced. In CS_2 nothing but anthracene (b) could be found, while in C_6H_6 the reaction product consisted chiefly of PhCH_3 (c), together with considerable amts. of *p*- and *m*-(PhCH_2) C_6H_4 (d), small amts. of (b) and PhMe (e), some high boiling hydrocarbons (not examd.), and some resinous matter. The formation of (b), (e) and (d) may be accounted for by assuming that the AlBr_3 changes (a) to CH_2Br_2 , part of which reacts with C_6H_6 like CH_2Cl_2 , giving (b) and (e) (Friedel and Crafts, *Ann.* [6] 11, 263), while another part gives with C_6H_6 PhCH_2Br , which interacts with (c) to form (d). The non-formation of the *o*-isomer of (d) may be explained in the same manner as the non-formation of *o*-xylene in the methylation of C_6H_6 (Jacobsen, *Ber.* 18, 338). H. M. GORDIN.

New method of making dibromomethyl ether and methylene bromide and iodide. V. E. TISECHENKO AND I. L. RABTZEVICh-ZUBKOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 705-8 (1914).—The method previously given for prepg. $(\text{CH}_2\text{Br})_2\text{O}$ (a) (*Ibid* 19, 472), while giving a good yield, is not convenient when larger amts. of it are needed, because then the satn. of $(\text{CH}_2\text{O})_2$ (b) with HBr requires several days. A much quicker method consists in mixing (b) with P, Br and H_2O : $2\text{P} + 10\text{Br} + 3\text{H}_2\text{O} + 10\text{CH}_2\text{O} = 2\text{H}_3\text{PO}_4 + 5(\text{CH}_2\text{Br})_2\text{O}$. If all the ingredients are mixed the H_2O will not suffice to properly moisten the mass. It is therefore better to take all the H_2O at once and add to it the P, Br and (b) in small portions at a time. Yield, 60%. When (a) is mixed with AlBr_3 there is an evolution of heat but no reaction at ordinary temp. On quickly heating this mixt. to $150-60^\circ$ a violent reaction takes place, and HBr is evolved in torrents. When heated only to $100-8^\circ$, or very slowly to $175-80^\circ$, the reaction is moderate, and the product upon addition of H_2O yields very pure CH_2Br_2 . Yield, 60%. Similarly with AlI_3 (a) yields CH_2I_2 . H. M. GORDIN.

Oxonium compounds of sulfuric acid with ethers. V. V. CHELINTZEV AND N. A. KOZLOV. *J. Russ. Phys. Chem. Soc.* 46, 708-25 (1914).—It having been shown by several investigators that ethers form definite chem. compds. with H_2SO_4 , C. and K. undertook to prep. these compds. in cryst. form, and to exam. them in respect to their

mol. wt. and heat of formation. The ethers used were Et_2O and $\text{iso-Am}_2\text{O}$, and the results obtained as follows: When 100% H_2SO_4 is mixed with either of these ethers and the mixt. cooled with liquid air, cryst. compds. are produced: $\text{H}_2\text{SO}_4 \cdot \text{Et}_2\text{O}$, m. -66.4° ; $\text{H}_2\text{SO}_4 \cdot 2\text{Et}_2\text{O}$, m. -88° ; $\text{H}_2\text{SO}_4 \cdot (\text{C}_6\text{H}_{11})_2\text{O}$, m. -47° ; $\text{H}_2\text{SO}_4 \cdot 2(\text{C}_6\text{H}_{11})_2\text{O}$, m. -74° . That in this reaction there is no decompn. of ether with formation of alkyl sulfate was proved by titrating the H_2SO_4 , both immediately after mixing the acid and ether in mol. quantities and after letting the mixt. stand for nearly 2 months. To each of the above compds. corresponds a definite thermal effect, the amts. of their heats of formation being: 6.83, 8.57, 6.15, 7.3 large cal., resp. Further addition of either of the ethers of these compds. causes no thermal effect whatever, the compds. merely going into soln. These solns. are homogeneous when both the ethers and the H_2SO_4 used are perfectly pure, otherwise an aq. layer seps. out. The compds. are readily sol. in MeOH , EtOH , AcOH , AcOEt , H_2SO_4 and POCl_3 , but almost insol. in hydrocarbons, EtBr , $\text{C}_2\text{H}_5\text{Br}$, and PhBr , and but slightly sol. in C_6H_6 . It is possible that at least in some of these solns. there is an interaction between solute and solvent with a replacement of the ethers by other mols. For the f. p. detn. of the mol. wts. of these compds. AcOH and POCl_3 were used as solvents. It was found that in both solvents there is a dissociation into the components and formation of complex compds. In the case of AcOH there is reason to assume the formation of $\text{H}_2\text{SO}_4 \cdot \text{AcOH}$ from the mono-etherates and $\text{H}_2\text{SO}_4 \cdot 2\text{AcOH}$ from the di-etherates. The etherates are supposed to be oxonium compds. having the formulas $(\text{R}_2\text{HO})_2\text{SO}_4$ and $\text{R}_2\text{HOSO}_4\text{H}$. Attempts were also made to obtain compds. from H_2SO_4 and methylal, ethylal and anisole. The amts. of H_2SO_4 consumed per mol. of these substances showed that in these cases there must be formation of both oxonium compds. and other complexes. H. M. GORDIN.

Gustavson's vinyltrimethylene and ethylidenetrimethylene. AL. FAVORSKII AND V. BATALIN. *J. Russ. Phys. Chem. Soc.* 46, 726-9(1914); cf. *C. A.* 8, 3443.

α -Thiitolene, α, α -iodothiitolene and α, α -thiitolene aldehyde. ANNA VLASTELITZA. *J. Russ. Phys. Chem. Soc.* 46, 790-800(1914).—The following modification of Paal's method for making α -thiitolene (a) (*Ber.* 19, 556) increased the yield to 49%. An intimate mixt. of Na levulinate, dried at 120° , P_2S_5 and sand was distd. and the distillate again mixed with P_2S_5 and sand and again distd. The product is purified by satg. it with KOH and distg. first over KOH and then over Na . By means of $\text{I} + \text{HgO}$ (a) was changed to α, α -iodothiitolene (b) (yield, 73%), yellowish oil of an agreeable odor, $b_{16.7} 94^\circ$, partly decomp. with liberation of I on exposure to light, d_4^{20} 1.8794, d_4^{24} 1.8734, MR 42.03, coeff. of surface tension 4.2535. By means of $\text{Mg} + \text{CH}(\text{OEt})_3$ (b) was converted into α, α -thiitolene aldehyde (c), which reacted with N_2H_4 to form the azine, $\text{C}_{12}\text{H}_{12}\text{S}_2\text{N}_2$, yellow crystals, m. $125.4-6^\circ$. When heated nearly to boiling for 1 hr. with $\text{AcOEt} + \text{NH}_3$ in alc., (c) gave diethyl α, α -dimethyl- γ - α -thiitolenylpyridinedicarboxylate, $\text{C}_6\text{H}_5\text{SCH.C}(\text{CO}_2\text{Et})\text{:CMe.NH.CMe:C}(\text{CO}_2\text{Et})$, white needles,

m. $148-8.4^\circ$. In presence of alk. (c) condenses with AcCH:CHPh to form benzylidenemethylthienylideneacetone, $\text{S.CMe:CH.CH:CCH:CHCOCH:CHPh}$ (yield

55%), yellowish needles with a pretty play of green and red colors, m. $58.5-60.5^\circ$, colors H_2SO_4 or HCl blood-red, but the color disappears upon addition of H_2O with sepn. of dark needles, is changed by HNO_3 and diln. with H_2O to rose-colored crystals. With PhNMe_2 in presence of ZnCl_2 at 100° (c) interacts to form tetramethyldiaminodiphenylthiotonylmethane (leucothiitolene blue-green), $\text{C}_6\text{H}_5\text{SCH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$, white needles, m. $131.4-1.8^\circ$; in alc. it oxidizes on exposure, turning intensely green. Tetramethyldiaminodiphenylthiotonylcarbinol (thiitolene blue-green), $\text{C}_6\text{H}_5\text{SC}(\text{OH})(\text{C}_6\text{H}_4\text{-$

NMe_2 ; (d), was made by acting with $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ on the Mg org. compd. of (b); bright gray, indistinctly cryst. powder, begins to char, without m., at 130° , sol. in Et_2O when fresh, but on standing in the air changes to an insol. modification; dissolves in strong acids, but is reprecipitated by H_2O ; its soln. in strong acids colors silk and wool raspberry-red, changing to blue-green upon addition of H_2O ; it is a fast dye and possesses great covering power. By the action of ZnCl_2 on (d) in HCl the zinc chloride double salt of thiolatene blue-green, $3[\text{C}_6\text{H}_4\text{SC}(\text{C}_6\text{H}_4\text{NMe}_2):\text{C}_6\text{H}_4:\text{NMe}_2.\text{Cl}].2\text{ZnCl}_2.3\text{H}_2\text{O}$, was obtained; brown crystals of a Cu luster, begins to char 150° , has a pretty blue-violet color in alc., colors fabrics blue.

H. M. GORDIN.

Note on the article of Stadnikov and Kuz'mina-Aron: "Action of carbonic anhydride on the etherates of alkyl-magnesium halides." A. E. CHICHIBABIN. *J. Russ. Phys. Chem. Soc.* 46, 800-2 (1914).—The conclusions in favor of Grignard's formula for the etherates of Mg org. compds., drawn by Stadnikov and Kuz'mina-Aron (*C. A.* 7, 983), are, according to C., untenable, their expts. being easily interpreted without regarding the etherates as oxonium compds. Thus the reaction between Ph_3CHOBu and PrMgI and the evolv. of CO_2 may be explained as follows: $\text{Ph}_3\text{CHO-Bu} + \text{PrMgI} = \text{Ph}_3\text{PrCH} + \text{BuOMgI}$. The latter reacts with CO_2 to give a mixed Mg salt of HI and BuOCO_2H : $\text{BuOMgI} + \text{CO}_2 = \text{BuOCO}_2\text{MgI}$. This salt is decomposed by mineral acids with evolv. of CO_2 : $2\text{BuOCO}_2\text{MgI} + 2\text{HCl} = 2\text{CO}_2 + \text{MgI}_2 + \text{MgCl}_2 + 2\text{BuOH}$. The unchanged Ph_3CHOPr which they recovered in the reaction of Ph_3CHOPr with PrMgI most probably contained a considerable amt. of Ph_3CHPr whose presence in the ether they failed to notice because the b. p. of both is the same. In general, G.'s formula cannot be accepted until a satisfactory explanation is given why the etherate obtained from Et_2O and AmMgI and that obtained from EtOAm and EtMgI give different products upon decompn. with H_2O (Chelintzev, *Individual Magnesium-Organic Compounds*, Moscow, 1908, 126). Unless additional hypotheses be made of there being a difference between the 4 valences of the O, the comp. of the etherate ought to be in both cases the same, Et_2AmOMgI , and, therefore, the decompn. products also ought to be the same.

Preparation of ethers from aldehyde and ketone acetals and magnesium organic compounds. A. E. CHICHIBABIN AND S. A. ELGAZIN. *J. Russ. Phys. Chem. Soc.* 46, 802-14 (1914); cf. *C. A.* 8, 3443.

H. M. GORDIN.

Menthol and some of its derivatives. N. I. KURSANOV. *J. Russ. Phys. Chem. Soc.* 46, 815-45 (1914).—When menthol (a) in C_6H_6 is carefully and with const. cooling added to PCl_5 covered with C_6H_6 , crude menthyl chloride (b) results, consisting of a mixt. of isomeric chlorides. Boiling KOH in alc. changes all of these to menthene (c), except the so-called permanent menthyl chloride (d), but the latter thus prep'd. is contaminated with some menthyl Et ether (e), while by heating (b) with PhNH_2 (200:214) to $160-70^\circ$ for 6 hrs., then acidifying with a weak acid, fractionating the product, and repeating these operations 3 times, (d) is obtained pure; liquid of agreeable odor, b_m $111-2^\circ$, b_{10} $109-10^\circ$, d_4^{20} 0.9365, d_4^{20} 0.9424, $[\alpha]_D^{20} -51.23^\circ$, is not decomposed by alc. KOH at 100° , but prolonged heating on a sand bath with PhNH_2 (1:3) changes it, as well as (b), to (c). From the impure (d) obtained from (b) and KOH it was not possible to isolate (e), but its presence therein was proved by boiling this (d) with an excess of Na in Et_2O . The product, consisting of (c), menthane (f) and cryst. dimethyl (g), had, after removing the (c) and the (f), the odor of (e), while (g) obtained from the pure permanent (d) by the same method was free of this odor. In still larger amt. is (e) produced when NaOH is used instead of KOH in the reaction with (b). Attempts to convert (d) into (a) by means of AcOAg or BzOAg were not successful, the reaction yielding nothing but (c). Grignard's reagent, without the addition of I, does not react with (d), but in presence of a small cryst. of I a reaction takes place with evolution

of heat. If after the reactions slacken the mixt is boiled for 3 hrs., and after cooling a current of O passed into it, the product is found to consist of (c), (f), (g) and natural (a) (purified by changing it to the acid menthyl phthalate and sapon.), without a trace of the other isomers of the latter. This shows that (d) is the menthyl chloride corresponding to natural (a). If, instead of (d), (b) is subjected to Grignard's reaction, and the product treated in exactly the same manner, the result is a mixt. containing both the products given under the same conditions by (d) and the liquid isomers of (g) and (a). If the reaction product of Grignard's reagent with either (d) or (b) is not boiled and treated with O as above, but a current of CO₂ is passed into it, menthancarboxylic acid (h) (Zelinskii, *Ber.* 35, 4417) is produced in both cases, but while from (d) only the cryst. modification of (h) is formed, and the latter is unaccompanied by other substances, (b) yields a mixt. of the cryst. and liquid isomers of (h), together with (c), (f) and the cryst. and the liquid isomers of (g). Owing to the presence of 3 asym. C atoms in (a), the latter ought to exist in 4 spatial configurations (I-IV) of which each

gives 2 antipodes and 1 (*l* + *d*) modification. To these 4 (a) correspond 4 (d). The formation of the 2 isomeric (g) from (b) in Grignard's reaction indicates that (b) contains at least 2 of these (d), but it is possible that it also contains some carvomenthyl chloride (V) and the tertiary chloride (VI). Since (VI) is incapable of giving (g) in Wurtz'

reaction (*J. Russ. Phys. Chem. Soc.* 33, 300), and since all the derivs. of (V) boil considerably higher than those of (a) (Bayer, *Ber.* 29, 824), while the liquid (g) boils at the same temp. as the crystals, we must assume that the formation of the 2 modifications of (g) is due to the presence in (b) of 2 of the isomers of (d), 1 giving the cryst., the other the liquid (g). If there be (VI) in (b), it may owe its formation to a splitting off and subsequent addition in another order of HCl. Of the 4 stereoisomeric (d) corresponding to (I-IV), the 2 corresponding to (I) and (III), having the tertiary H of the CH to which the C₂H₅ group is linked further removed from the Cl (*trans*-arrangement), are stable, while the other 2 (d), corresponding to (II) and (IV) in having that H nearer to the Cl (*cis*-arrangement), are unstable. Since only 2 isomeric (h) are produced from (b), it must contain only 2 isomeric (d), 1 stable, the other unstable. The formation of only 2 of the 4 possible chlorides from (a) by PCl₅ is due to the fact that only the groups attached to the C linked to the OH in (a) undergo a spatial rearrangement, giving a stable and an unstable compd., the groups attached to the other 2 asym. C atoms remaining unchanged. Hence, of the 2 chlorides in (b) 1 corresponds to either (II) or (IV), the other to either (I) or (III). Since pure (d), representing the stable modification, is a *trans* compd., natural (a), being obtainable from it, must also be a *trans* compd., either (I) or (III), while the liquid (a) must be a *cis* compd. For a complete

knowledge of the configuration of natural (*a*) we would have to know the spatial positions of the H and the Me at the 3rd asym. C. While this knowledge is lacking, we have reason to assume that in natural *l*-(*a*) the C to which the iso-Pr is linked is *l*-rotatory, while the C attached to the Me is *d*-rotatory. This conclusion is arrived at by a somewhat lengthy consideration of the relation between the rotations of natural (*a*) and *l*-menthone (*i*), in connection with the fact that the latter is converted by H_2SO_4 into isomenthone which is not the antipode of (*i*), its *d*-rotation being greater than the *l*-rotation of (*i*) (Beckmann, *C. A.* 3, 1273). The cryst. and the liquid (*b*) correspond to *trans*- and *cis*-(*a*), resp., while the ethylmenthane previously described (*J. Russ. Phys. Chem. Soc.* 33, 301), having the Et in the same position as the OH in natural (*a*), has a configuration like the latter. Similarly the configuration of the cryst. (*g*) is given by the relation of the latter to natural (*a*). Menthyl phenyl ether, $\text{C}_{11}\text{H}_{19}\text{OPh}$ (*j*), was prepd. as follows: K was heated with double the required amt. of (*a*) till soln. was effected. To the resulting K mentholate a very slight excess of PhI (*k*) and a small amt. of finely divided Cu (*Naturkupfer*, Ullmann and Sponagel, *Ber.* 38, 221) were added, and the mixt. heated to 140° , when a ppt. began to appear and brisk boiling set in, which continued even after the removal of the source of heat. When the boiling ceased the mixt. was heated for 8 hrs. to $150\text{--}60^\circ$ and then fractionated by distn. 40% of (*k*) was recovered as C_6H_6 , part of the mentholate was reduced to (*a*), and another part oxidized to menthone, while the yield of (*j*) was 40%; needles, m. $52\text{--}3^\circ$, b_{11} $150\text{--}1^\circ$, $[\alpha]_D^{20} -128.11^\circ$, easily sol. in org. solvents. If the Cu is omitted the result is a mixt. of C_6H_6 and much resin, but contains no (*j*). Similar results were obtained by using PhBr instead of (*k*), but in this case the reaction is less energetic, and the yield of (*j*) only 20%. In the same way, by replacing K with Na the yield of (*j*) drops to 25%. The relation of (*j*) to natural (*a*) shows it to be a *trans* compd. By the same method, in presence of Cu, PhOEt was obtained from (*k*) + EtOK (yield 35%) and from (*k*) + EtONa (yield, 45%), while in absence of Cu the reactions gave nothing but C_6H_6 , the expected AcH evidently being completely resinified. Heated alone in a sealed tube to 250° for 3 hrs. (*j*) remains unchanged, but when heated with a little HCl to 170° it gives PhOH, the unstable (*d*) (proved by its yielding (*c*) with KOH in alc.) and a mixt. of isomeric menthylphenols, $\text{C}_{10}\text{H}_{19}\text{C}_6\text{H}_4\text{OH}$ (*m*), immobile resin at ordinary temp., vitreous mass. at very low temp., and oily liquid at 100° , b_{11} $179\text{--}86^\circ$, optically inactive, is converted by alkali into almost insol. phenolates that are completely hydrolyzed by H_2O , gives a urethan $\text{C}_{22}\text{H}_{31}\text{O}_2\text{N}$, m. 141° , from the mother liquor of which a small amt. of another cryst. substance, m. 136° , was isolated. The isomerization of (*j*) to (*m*) is not as simple as the isomerization of $\text{PhOCH}_2\text{CH:CH}_2$ to $\text{CH}_2\text{:CHCH}_2\text{C}_6\text{H}_4\text{OH}$ (Calisen, *C. A.* 6, 1016) where no intermediate substances are formed. It is proved by expts. that (*m*) may also be made by the interaction of (*d*) with PhOH, and that this reaction is reversible. Hence the isomerization of (*j*) to (*m*) is due to the action of the (*d*) on the PhOH produced intermediately, the reaction taking place in 2 steps: $\text{C}_{10}\text{H}_{19}\text{OPh} + \text{HCl} = \text{C}_{10}\text{H}_{19}\text{Cl} + \text{PhOH}$, $\text{C}_{10}\text{H}_{19}\text{Cl} + \text{PhOH} \rightleftharpoons \text{C}_{10}\text{H}_{19}\text{C}_6\text{H}_4\text{OH} + \text{HCl}$. Since the HCl is constantly regenerated, its effect is merely catalytic, and a mere trace of it will suffice to isomerize (*j*) to (*m*). Owing to the reversibility of the reaction between (*d*) and PhOH, (*m*) may be produced in as large a yield as 82% by heating them, not in a sealed tube, but in a vessel closed only with a CaCl_2 tube, so that the HCl is driven off as soon as produced. The (*m*) obtained from (*d*) + PhOH is sometimes very slightly *l*-rotatory, and that part of (*d*) which fails to react is found to have changed to its unstable modification, though the latter also reacts with PhOH to give (*m*). The isomerization of (*j*) to (*m*) seems to be but a particular case of a general reaction. Thus PhOEt may be converted by the same method to $\text{EtC}_6\text{H}_4\text{OH}$. The work in this direction is to be continued.

H. M. GORDIN.

Action of ethylmagnesium iodide on α -thienyl ethyl ketone. E. DOMRACHEVA. *J. Russ. Phys. Chem. Soc.* 46, 864-7(1914).— α -Thienyl Et ketone (a) was made by the action of EtCOCl on thiophene in presence of AlCl₃. Yield, 60%. Treated with EtMgI in Et₂O and decompd., with NH₄Cl, (a) gave *diethyl- α -thienylcarbinol*, Et₂-(C₄H₃S)COH (b), thick liquid, solidifying to a glassy mass when cooled with liquid CO₂, b₁₈ 116-70°, d₄^{15.6} 1.0779, MR 48.66. Heated for 1 hr. to 120° with (CO₂H)₂, (b) loses H₂O, changing to *methylethylthienylethylene*, MeCH:CEt(C₄H₃S) (c), liquid of a characteristic odor, b₁₈ 90-1.5°, solidifies to a vitreous mass at -80°, takes up 2 atoms of Br, but the resulting bromide at once begins to lose HBr and resinifies, yields upon oxidation with KMnO₄ a small amt. of α -thiophenecarboxylic acid. The formation of (c) was accompanied by a *dimer* C₁₈H₁₄S₂, thick yellowish liquid of a feeble odor, b₁₈ 213-8°.

H. M. GORDIN.

Reaction of esters with magnesium organic compounds. I. G. L. STADNIKOV. *J. Russ. Phys. Chem. Soc.* 46, 868-87(1914).—The comp. of the complex produced in the 1st stage of interaction of an ester RCO₂R' with a Mg org. iodide R'MgI is according to Chichibabin (*J. Russ. Phys. Chem. Soc.* 37, 180; 38, 327) RR'C(OR')OMgI, while according to Reformatskii it is RCOR". Usually an excess of the Mg org. iodide is used in the reaction, the mixt. is warmed, and then decompd. with H₂O. Under these conditions the above complex reacts with another mol. of the Mg org. iodide, and the final product, usually being a tertiary alc., gives no clue to the comp. of the complex formed in the 1st stage of the reaction, since a compd. of either of the above formulas may thus be made to yield such an alc. If, however, only 1 mol. each of ester and Mg org. compd. be used, or the product, without being warmed, be at once decompd. with H₂O, there ought to be produced, according to these formulas, a ketone and the alc. whose ester was taken in the reaction. Since S.'s expts. prove that in this case the product is the unchanged ester, the above mentioned complex cannot have either of the formulas assigned to it by C. or R. We must rather assume that the complex is an oxonium compd., either RCOO(R')(I)MgR" (Bayer), or RCOO(R')-(R')MgI (Grignard). With B.'s formula it is difficult to explain the frequent formation in this reaction of ketones RCOR", and still more that of iodo-Mg alcoholates R'OMgI, without resorting to several clumsy hypotheses, e. g., the splitting off of the radical R" from the Mg, and of the I from the O, the migration of I from O to Mg, etc. These difficulties are overcome by G.'s formula which plausibly explains the above as well as all other transformations of esters in their interaction with Mg org. halides. Moreover, G.'s formula enables us to foresee several abnormal transformations which have never been observed and which B.'s formula does not even suggest. These transformations of the complex are as follows: RCOO(R')(R')MgI $\rightarrow$ RCOR' + R'OMgI (1), RCOR' + R'OMgI (2), RCOOMgI + R'.R" (3) and RCOOMgI + 0.5R'.R' + 0.5R".R" (4). Of these, (1) is the usual transformation where the ketone reacting with another mol. of the Mg org. compd. would give a tertiary alc. which, when its mol. wt. is high, will yield the corresponding hydrocarbon, while (2), (3) and (4) are abnormal transformations. Hence the proof that these really take place would conclusively prove that G.'s formula is preferable to B.'s. The proof then reduces itself to an exam. of the transformations of the alc. radical R' of the ester used. As the problem is easiest to solve when R' has a high mol. wt. and, therefore, gives readily isolated products, expts. were made with esters containing "heavy" radicals, using the reaction of AcOCHPh₂ with EtMgI, iso-AmMgI, PrMgI, BuMgI and PhMgI, and of BzOCH₂Ph with PhMgBr. The expts. proved that the above abnormal transformations really occur. Thus, to cite 1 of the numerous expts., AcOCHPh₂ + PrMgI gave as final products C₆H₅, C₆H₆, (Ph₂CH)₂, (Ph₂CH)₂O, Ph₂CHOH and MePrCHOH, together with an unidentified substance, b₁₂

146–53° and containing 90% of C. Hence the complex must be assumed to be $\text{AcO}(\text{CHPh}_2)(\text{Pr})\text{MgI}$, and its decompn. to be as follows: $\text{AcO}(\text{CHPh}_2)(\text{Pr})\text{MgI} = \text{AcO-MgI} + 0.5(\text{Ph}_2\text{CH})_2 + 0.5\text{C}_2\text{H}_6 + 0.5\text{C}_3\text{H}_8$, the other substances resulting from secondary transformations. As this is partly normal and partly according to (4), G.'s formula is to be preferred.

H. M. GORDIN.

Abnormal course of Grignard's reaction. G. L. STADNIKOV. *J. Russ. Phys. Chem. Soc.* 46, 887–9 (1914).—According to Grignard (*Ann. chim. phys.* [7] 24, 474), the result of the interaction of HCO_2Et (a) with iso-AmMgBr is not the expected secondary alc., but iso-AmO₂CH (b), while with iso-BuMgBr (a) gives, besides (iso-Bu)₂CHOH, the ester iso-BuO₂CH (c). In order to account for the abnormal formation of (b) and (c), S. assumes that, owing to the slowness of the reaction of (a) with Mg org. compds., there is gradually formed an alcoholate of the Mg halide, and that this alcoholate reacts with (a) to give (b) and (c). Hence if we would start with such a ready made alcoholate, it would react with an ester, converting the latter to the ester of that alc. whose alcoholate we use, provided the 2 alc. radicals are different. If, however, these are identical there would be no reaction at all. This is proved by the following expts.: AcOCHPh_2 (d) + Ph_2CHOMgI (e) did not react with each other, while AcOEt + (e) gave (d), and AcOEt + the iodo-Mg alcoholate of β -methylcyclohexanol gave β -methylcyclohexyl acetate. The expts., embracing also the esters of inorg. acids, are to be continued. It is possible that with these the iodo-Mg alcoholates will react differently than the full alcoholates $(\text{RO})_2\text{Mg}$ (Rabtzovich-Zubkovskii, *C. A.* 6, 1431).

H. M. GORDIN.

The higher valences of oxygen in organic compounds. VI. Basic properties of oxygen in ethers. V. V. CHEKLINTZEV. *J. Russ. Phys. Chem. Soc.* 46, 889–95 (1914).—Calorimetric detns., similar to those previously made with alcs. in their interaction with ROMgI (*C. A.* 8, 1419), were now made with ethers, using PrOMgI and Et_2O , PhOEt , $\alpha\text{-C}_{10}\text{H}_7\text{OEt}$, $\beta\text{-C}_{10}\text{H}_7\text{OEt}$, Ph_2O , PhCH_2OEt , Ph_2CHOEt , Ph_2COEt and $(\text{PhCH}_2)_2\text{O}$. The results, given in numerous tables, may be summarized as follows: While alcs. unite with ROMgI to form compds. of different complexity according to what alcs. are used, the comp. of the ether compds. is much simpler, all of these having the formula $\text{R}_2\text{O}(\text{MgR})\text{I}$. As shown by the thermal effects of the reactions, the tendency of ethers to exhibit higher valences of O is less pronounced than in alcs. Thus the thermal effect for EtOH is 12.78 cal., while for Et_2O it is 5.05 cal. The more negative the radical and the "nearer" it is to the O the less is the thermal effect. Thus the values for Et_2O , PhCH_2OEt and PhOEt are, resp., 5.05, 4.19 and 0 cal. The ethers corresponding to aliphyl alcs. thus occupy an intermediate position between alkyl and aryl ethers. An accumulation of Ph groups causes a gradual drop in the thermal effect. Thus the values for PhCH_2OEt , Ph_2CHOEt and Ph_2COEt are, resp., 4.19, 2.04 and 0 cal. The transfer of a Ph from 1 of the radicals to the other, provided it is not brought "nearer" to the O, also influences the thermal effect, though to a lesser extent. Thus the values for Ph_2CHOEt and $(\text{PhCH}_2)_2\text{O}$ are, resp., 2.04 and 1.57 cal. Comparing the tendency of alcs. and ethers to form complexes with that of H_2O in this respect, it is seen that the replacement of the H in H_2O by radicals gradually diminishes the tension of O in its tendency to assume higher valences. Thus the thermal effects for H_2O , ROH and R_2O represent a descending series. This explains why H_2O displaces alcs. and ethers from their complexes.

Polymerization of styrene. II. HANS STOBBER. *Univ. Leipzig. Ann.* 409, 1–13 (1915); cf. *C. A.* 4, 2120.—The earlier conclusions concerning the course of the polymerization of styrene to metastyrene, obtained by the help of viscosity detns., have been confirmed by the use of refraction detns. Besides the earlier observed "photochem." there is also a "thermal after-effect," that is, styrene preps. which have

been treated with light or heat polymerize more rapidly under the same conditions than those not treated. Old styrene prepn. show a greater tendency to polymerize than freshly distd. samples.

C. J. WEST.

Determination of the configuration of stereoisomeric stilbenes and their carboxylic acids. R. STÖRMER. Univ. Rostock. *Ann.* 409, 13-9(1915); cf following abstr.—The configuration is related to the CO₂H acids. The stable α -acid (I), m. 172, when heated with Ba(OH)₂ in vacuum at 300°, gives considerable amts. of isostilbene besides a little solid stilbene. The formation of the latter is due to secondary rearrangements of the isostilbene. The labile acid, m. 137-8° (II), under the same conditions also gives a mixt. of much stilbene with some isostilbene. This formation of isostilbene is due to a rearrangement of the acid. The configuration of the acids is detd. as follows: The NO₂ deriv. of (I), when reduced and diazotized, gives phenanthrenecarboxylic

acid, thus establishing the *cis*-position for the 2 Ph groups. The stereoisomeric NO₂ deriv., upon reduction, gives allo- α -phenyl-*o*-aminocinnamic acid, obtained only in the form of salts. The free base at once gives phenylcarbostyryl, while if the Ba salt is diazotized and the soln. boiled, α -phenylcoumarone is formed. These facts establish the *cis*-position of the NO₂ and CO₂H groups in this acid. If the diazo soln. is poured into hot satd. Na hypophosphite soln. containing Cu, a good yield of (II) is obtained, which thus establishes its constitution.

C. J. WEST.

The stereoisomeric α -phenyl-*o*-nitrocinnamic acids and other stilbene derivatives. R. STÖRMER and L. PRIGGE. Univ. Rostock. *Ann.* 409, 20-35(1915); cf. preceding abstr.—The stable (high-melting) O₂NC₆H₄CH: CPhCO₂H (A) is dissolved in Na₂CO₃ in a vessel of uvial glass and treated 7 days with the rays of an uvial lamp; the unchanged stable acid is pptd. with 50% AcOH, the ppt. quickly filtered and the filtrate acidified with concd. HCl. The yield of the low melting acid (B) is 10.7% after 7 days, 13.8% after 14 days and 16% after 21 days. The labile acid gives a 0.47% soln. in C₆H₆ at 18° while the stable acid gives a 0.28% soln. The allo-acid (low-melting) is not changed by boiling an hour with dil. HCl, shaking with cold or warm concd. H₂SO₄, by heating 3 hrs. with 1 mol. I in C₆H₆ or by treatment with sunlight in the presence of Br. After 48 hrs. in the light of a quartz lamp a small amt. of the high-melting acid was obtained. (A) *amide*, pale yellow needles from C₇H₈, m. 173-4°. *Anilide*, citron-yellow needles, m. 136°. (B) *amide*, citron-yellow, m. 166-7°. *Anilide*, yellowish white, m. 148-9°. If the stable NO₂ acid is reduced, the 2 forms of H₂N-C₆H₄CH: CPhCO₂H (C), colorless and yellow, are obtained (Pschorr, *Ber.* 29, 497, 1896). When this is dissolved in C₆H₆ and treated with the rays from an uvial lamp, a good yield of phenylcarbostyryl is obtained. Attempts to replace the diazo group by H failed, the only product being phenanthrenecarboxylic acid. The use of Cu powder in this reaction is not necessary. As a by-product a small amt. of Na₂CO₃-insol. substance is obtained, which is α -phenylcoumarin. This results from a very small amt. of α -phenylcoumaric acid, which is decompd. by boiling H₂O. The compd. C₁₇H₁₄O₂ described by Mayer and Balle (*C. A.* 8, 1738), m. 146-7°, is *phenylmethylcoumarin*, C₁₆H₁₂O₂. This was synthesized by condensing MeC₆H₄(OH)CHO with Ph-CH₂CN and boiling with concd. HCl. The allo-acid (B) upon reduction of an NH₄OH soln. by FeSO₄ and Ba(OH)₂ yields *phenylcarbostyryl*, felt-like needles, m. 227°. The existence of the Ba salt of the aminocinnamic acid follows from the production of a red dye when diazotized and treated with R salt. The Ba salt, when diazotized, poured into cold H₂SO₄, filtered from BaSO₄ and boiled, gives α -phenylcoumarin. If the Ba

salt is diazotized in HCl and allowed to flow slowly into a hot soln. of Na hypophosphate containing a little Cu powder, a good yield of pure *allo-α-phenylcinnamic acid* is formed. *p-Methoxystilbenecarboxylic amide*, porcelain-like leaflets, m. 131.5–2.5°. The stable *p-MeO* acid, treated as above with the rays of the uvioi lamp, gives 20% of the *allo*-form after 8 days, 30 after 21 days; this is sepd. by extg. the HCl ppt. with dil. alc.; hard crystal aggregates, m. 123°. At 15° C_6H_6 forms a 1.945% soln. The reverse change is accomplished by treating the soln. in C_6H_6 , containing I, with the rays of a quartz lamp for 24 hours. *Aniline salt* of the *allo* acid, m. 116°, easily dissociates into its components. *Amide*, fine needles, m. 168–9°. *p-Methoxystilbene* in C_6H_6 is converted into *allo-p-methoxystilbene* by the uvioi lamp, 45.7% being formed in 14 days; an oil, $b_{1.5}$ 143–5°, which is changed into the stable modification when heated at 170° under 15 mm. *o-Nitrostilbene* was prepd. by reducing the diazo sulfate with $C_6H_{11}OH$ and Cu, m. 72–3°. By treatment with the rays of the uvioi lamp, *allo-o-nitrostilbene* is formed, citron-yellow needles, m. 42°. It could not be reconverted into the stable form. Upon reduction with $SnCl_2$ and $AcOH-HCl$, both NO_2 compds. gave the same NH_2 deriv., m. 106°. $FeSO_4$ and NH_4OH gave an oily base. C. J. WEST.

Stereoisomeric α -substituted cinnamic acids. R. STOERMER AND G. VOHT. Univ. Rostock. *Ann.* 409, 36–58(1915); cf. preceding abstr.—*Allo-α-phenylcinnamic acid* (A) is best obtained by treating the Na salt of the stable acid (B) with the rays of the uvioi lamp for 3 weeks or with those of a quartz lamp for 3–4 days. H_2O , C_6H_6 , $EtOH$ or acetone solns. of the free acid may also be used. The yield is about 30%. The stable acid is pptd. with $AcOH$ while the labile form remains in soln. and is pptd. with dil. HCl. (B) *amide*, needles, m. 127°. *Anilide*, m. 141°. (A) *amide*, m. 167–8°. *Anilide*, m. 179°. About 50% of (B) is obtained when (A) in C_6H_6 containing I is treated with the rays of a quartz light for 24 hrs. Both acids possess about the same stability, especially seen in the fact that upon heating either acid a mixt. of both is obtained. If the stable acid is boiled under 20 mm. very little of the labile form is obtained while under the same conditions the labile acid gives a large amt. of the stable. When the acids are distd. with twice their wt. of $Ba(OH)_2$ under 12–13 mm., the stable form yields isostilbene besides some stilbene, while the labile form gave principally stilbene. *Allo-α-phenylcinnamic nitrile* is obtained by the action of the rays of the uvioi lamp upon a C_6H_6 soln. of the stable form for 3 weeks., and sepd. by extrn. with alc. or petroleum ether, b_m 213–4°. At 19° it gives a 17.3% soln., while the solid isomer gives a 2.3% soln. By distn. under ordinary pressure the solid form is obtained. *Allo-α-phenoxy-cinnamic acid*, prepd. by treating a large amt. of the stable acid in alc. with the rays of a quartz lamp for 48 hrs. and extg. with petr. ether, hair-like needles, m. 73°. Petr. ether forms a 0.4% soln. at 16°, while the stable form gives a 0.03% soln. *Amide*, fine needles, m. 107°. *Aniline salt*, m. 98–9°. *Amide of stable form*, compact needles, m. 172°. The configuration of the acids is not known. The stable acid, m. 181°, treated with P_2O_5 , gives an anhydride but not indone, thus indicating the structure (I).

α -Phenoxy-*p*-methoxycinnamic acid, m. 200°, was prepd. by heating 100 g. $PhOCH_2CO_2Na$, 80 g. $MeOC_6H_4CHO$ and 300 g. Ac_2O 6 hrs. at 150°, esterifying and fractionating the mixt. in vacuum. The fraction b. 220–40° and m. 63° is sapond. Treated in 10% Na_2CO_3 for 48 hrs. with the rays of the quartz lamp, 15 g. acid gives 3.5–4.0 g. crude *allo*-acid, needles, m. 120°. *Aniline salt*, m. 113°. *Amide*, long needles, m. 123–4°. *Amide of stable form*, needles, m. 194°. α -Methylcinnamic acid, recrystd. from dil. alc., m. 81–2°. Repeatedly recrystd. from petr. ether, the m. p. drops to 73–4°.

while a mixt. of the two m. about 78° . This accounts for the 3 forms described in the literature. These acids dissolve completely in concd. H_2SO_4 and are pptd. by H_2O . They give a Me ester, b_{16} $137-8^{\circ}$, m. $38-8.5^{\circ}$. The acid does not give a PhNH_2 salt but yields a *phenylhydrazine salt*, voluminous crystals, m. $64-5^{\circ}$. The *allo-acid*, sepd. from the stable form by petr. ether, forms compact monoclinic prisms and hemipyramids, m. $91-2^{\circ}$. Boiled 4-5 hrs. with 20% HCl , it gives the lower melting form. *Aniline salt*, felt-like needles, m. $74-4.5^{\circ}$. *Methyl ester*, oil, b_{16} 122° . *Amide*, fine needles, m. $137-8^{\circ}$. The characteristic reaction of this acid is the formation of α -methylindone, by adding the acid to concd. H_2SO_4 cooled to -2° and after soln. (2 min.) pouring into ice-water, yellow prisms, b_{16} $119-20^{\circ}$, m. $47-7.5^{\circ}$. It is volatile with Et_2O vapors. It is rather unstable and after several days forms an oil. The *phenylhydrazone* is a dark yellow oil. *Semicarbazone*, deep yellow needles, m. $192-3^{\circ}$. *Allo- α -ethylcinnamic acid*, obtained only as an oil, yields an *aniline salt*, m. 81° . This acid gives α -ethylindone, yellow oil, the *semicarbazone* of which forms yellow needles m. 181° .

C. J. WEST.

New method for preparing cyclic ketones. II. Preparation of thioethers and thioxanthenes of the anthraquinone series. ALFRED SCHAARSCHMIDT. Berlin. *Ann.* 409, 59-78(1915); cf. C. A. 8, 2358.—1-Cyano-2-anthraquinonyl *p*-tolyl thioether (A), prepd. by boiling 4 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$, 1.8 g. *p*- $\text{HSC}_6\text{H}_4\text{Me}$ and 1 g. K_2CO_3 in 50 g. $\text{C}_6\text{H}_{11}\text{OH}$ for 1 hr., slightly yellow needles from AcOH , m. 251° . Yield, 3 g. Concd. H_2SO_4 gives a violet-red soln. which becomes yellowish red upon heating to $130-40^{\circ}$, due to the formation of the thioxanthone. The alk. $\text{Na}_2\text{S}_2\text{O}_4$ bath is a deep bluish green. 1-Cyano-2,1'-dianthraquinonyl thioether (B), obtained by boiling 5 g. $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3\text{SH}$, 6.3 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$ and 3 g. K_2CO_3 in 100 g. $\text{C}_6\text{H}_{11}\text{OH}$ 1 hr., deep yellow needles from PhNO_2 , does not m. 310° . Yield, 7.5 g. The alk. dye bath is brownish red and dyes cotton a pale yellow. The concd. H_2SO_4 soln. is red. "Fenchosol," colorless mobile liquid, d. 0.952, b. $193-6^{\circ}$, miscible with most organic solvents in all proportions, may also be used for this condensation. 1-Cyano-2,2'-dianthraquinonyl thioether (C) is obtained in a yield of 4.7 g. by boiling 3.1 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$, 2.5 g. 2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3\text{SH}$ and 0.8 g. K_2CO_3 in 100 g. $\text{C}_6\text{H}_{11}\text{OH}$ 1 hr., fine light yellow needles from much PhNO_2 , does not m. 310° . The concd. H_2SO_4 soln. is red, the alk. $\text{Na}_2\text{S}_2\text{O}_4$ bath yellow brown. Di-[1-cyano-2-anthraquinonyl]-1',5'-anthraquinone dithioether (D), prepd. by heating 3.1 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$, 1.4 g. 1,5- $\text{HSC}_6\text{H}_3(\text{CO})_2\text{C}_6\text{H}_3\text{SH}$ and 1 g. K_2CO_3 in 70 g. $\text{C}_6\text{H}_{11}\text{OH}$ 2 hrs., yellowish orange powder from PhNO_2 , in which it is very slightly soluble. The alk. dye bath is green, dyeing cotton a pale yellow. The product is insol. in cold concd. H_2SO_4 . 1-Cyano-2-anthraquinonyl phenyl thioether (E), prepd. by heating 2.1 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$, 1 g. PhSCN and 1 g. K_2CO_3 in 30 g. $\text{C}_6\text{H}_{11}\text{OH}$ until soln. results, glistening yellow needles, m. 207° . The soln. in concd. H_2SO_4 is carmine-red, in $\text{Na}_2\text{S}_2\text{O}_4$ deep bluish green. (B) is also obtained by boiling 1.5 g. 1,2- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3(\text{CN})\text{Br}$, 1.3 g. 1- $\text{C}_6\text{H}_4(\text{CO})_2\text{C}_6\text{H}_3\text{SCN}$ and 0.7 g. K_2CO_3 in 30 g. $\text{C}_6\text{H}_{11}\text{OH}$ for 0.75 hr. Thioxanthone of (A) (I), obtained by heating 1 part (A) with 10 parts 96% H_2SO_4 10 hrs. at 100° ,

yellow plates from AcOH. The concd. H_2SO_4 soln. is red, the alk. dye bath blue olive-green; it dyes cotton a pale green which is oxidized to a very pale yellow by the air. *Thioxanthone of (B) (II)*, obtained by heating 1 part (B) with 10 parts 96% H_2SO_4 0.75 hr. at 190° , brownish orange powder from 100 parts PhNO_2 . The alk. dye bath is bluish green, dyeing cotton a deep bluish green, which is oxidized by the air, more rapidly by dil. NaOCl , to a yellow-orange. *Thioxanthone from (C) (III)*, yellow powder,

(III)

(IV)

giving a red soln. in concd. H_2SO_4 , olive-green in $\text{Na}_2\text{S}_2\text{O}_4$. Cotton is dyed olive and becomes yellow upon oxidation. *Thioxanthone from (D) (IV)*, purified by extn. with dil. NaOH and then with PhNO_2 . The hot $\text{Na}_2\text{S}_2\text{O}_4$ soln. is a black-blue, which dyes cotton the same color and is oxidized to an orange-red by NaOCl . C. J. WEST.

Tetrahydropyridines and their behavior towards aldehydes. A. LIPP AND E. WINMANN. München. *Ann.* 409, 79-147(1915); cf. *Ann.* 294, 141(1897); *Ber.* 38, 2471(1905).—Certain γ - and δ - NH_2 ketones are not stable but split off H_2O , giving the corresponding tetrahydropyridines and pyrrolines. If H or an alkyl residue is attached to the N, neither the free ketone nor the salts are stable, while if an aryl group is present the free ketone is stable in soln. and only upon salt formation do they form condensation products. Certain ring compounds earlier described are, therefore, when in soln., really NH_2 ketones and react as such. *N*-Methyltetrahydropicoline (A) is, in soln., really *N*-methylaminobutyl methyl ketone, $\text{MeHN}(\text{CH}_2)_3\text{Ac}$; of its derivs. the benzoyl compound, the oxime and the semicarbazone have been described. HCHO reacts with an aq. soln. of *N*-methyltetrahydropicoline at room temp. and even at 0° to give *N*-methyl- β -acetopiperidine (B) (cf. Ladenburg, *Ann.* 301, 117(1898)); many of these compds. have been prepd. by L., who, however, assigned other structures to them. (These are given in parentheses following the correct names). Of this the oxime, phenylhydrazones hydrochloride, semicarbazone and its hydrochloride have been described. Upon reduction with Na-Hg in dil. HCl or with Na and EtOH , it yields *N*-methyl- β -piperylmethylalkine (*N*-methylpipecolylalkine), $\text{C}_8\text{H}_{15}\text{NMeCHOH-Me}$, b_{715} 214.5-6.5°. The presence of the $>\text{CHOH}$ group is indicated by oxidation to (B). 12.5 g. AcH in 200 g. H_2O dropped into 28 g. (A) in 400 cc. cold H_2O and allowed to stand 60 hrs. gave 41 g. *N*-methyl- α -methyl- β -acetopiperidine (C) (*N*-methyl- α -pipecolyl- β -methylalkine). Oxime, hone-like prisms, m. $129-31^\circ$. Hydrochloride, prisms, m. $191-3^\circ$ (decompn.). Semicarbazone, tables, m. $168-70^\circ$ (decompn.). Reduced with Na-Hg in H_2O (C) gives *N*-methyl- α -methyl- β -piperylmethylalkine (D), b_{715} 224-26°. Chloroaurate, m. 148° , easily sol. in H_2O at $40-50^\circ$. Mercuric chloride double salt, $\text{C}_8\text{H}_{15}\text{NO} \cdot \text{HCl} \cdot 6\text{HgCl}_2$, short, rectangular prisms, m. $170-2^\circ$, easily sol. in hot H_2O . Heated with 4 parts concd. HCl at $180-90^\circ$ for 3 hrs., (D) splits off H_2O , yielding *N*, α -dimethyl- β -vinylpiperidine (*N*-methyl- α , β -propylene-

piperidine), which is reduced by Zn and HCl to *N*, α -dimethyl- β -ethylpiperidine (*N*-methyl- β -isopropylpiperidine). *N*-Ethyl- Δ^2 -tetrahydro- α -methylpyridine (*N*-ethyl- α -pipecoleine) (*E*), b_{710} 167–70°. *Picrate*, monoclinic prisms, *m.* 126°. In aq. soln. this base exists as the free ketone, *N*-ethylbutyl methyl ketone. *Benzoate*, monoclinic prisms, *m.* 56–7°. *Benzoate oxime*, thick oil. *Oxime*, rhombic tables, *m.* 96–7°. *Semicarbazone hydrochloride*, small prisms, *m.* 166–8°. *N*-Ethyl- β -acetopiperidine (*N*-ethyl- α -pipecoleyl- β -alkine) (*F*), prepd. by dropping 18 g. 40% HCHO into 25 g. (*E*) in 250 g. H₂O. *Oxime*, prisms, *m.* 128–9°. *Semicarbazone*, *m.* 160° (decompn.). *Phenylhydrazine hydrochloride*, yellow, rhombic tables, *m.* 217–8° (decompn.). Upon reduction (*F*) gives *N*-ethyl- β -piperylmethylalkine (*N*-ethyl- α -pipecolyl- β -alkine). *Mercuric chloride salt*, C₈H₁₈NO.HCl.3HgCl₂, rhombic tables, *m.* 121°. (*F*) is easily obtained upon oxidation. Heated with HCl at 180–90°, (*F*) gives *N*-ethyl- β -vinylpiperidine (*N*-ethyl- α , β -ethylenepiperidine). *Chloroplatinate*, *m.* 176° (*L.*, 162°). *Mercuric chloride salt*, *m.* 155° (*L.*, 82°). Upon reduction, *N*, β -diethylpiperidine is formed, b_{710} 177–85°. *Hydrochloride*, prisms, *m.* 186–8°. *N*-Ethyl- α -methyl- β -acetopiperidine (*N*-ethyl- α -pipecoleyl- β -methylalkine) (*G*). *Chloroplatinate*, *m.* 187° (*L.* 167°). *Mercuric chloride salt*, C₁₀H₁₈NO.HCl.6HgCl₂, sinters 140°, *m.* 200° (*L.* gives 3 HgCl₂ and *m.* 116°). *Oxime*, oily. *Chloroplatinate*, yellow powder, *m.* 185° (decompn.). *Semicarbazone*, leaflets and tables, *m.* 184–6°. *Chloroplatinate*, begins to decomp. 150°. Upon reduction (*G*) gives *N*-ethyl- α -methyl- β -piperylmethylalkine (*N*-ethyl- α -pipecolyl- β -methylalkine). α , β -Dimethyl- Δ^2 -tetrahydropyridine (*H*) was obtained by heating a mixt. of 54 g. Br(CH₂)₂N(CO)₂C₆H₄ and 34 g. AcMeCNaCO₂Et in 100 cc. abs. alc. 4 hrs., distg. the phthalimidopropylmethylacetate with steam, and heating 4–5 hrs. with HCl (*d.* 1.10) and then heating the remaining oil with HBr (*d.* 1.49) in a sealed tube at 185–90° for 2 hrs. The aq. soln. of the base treated with BzCl gives 1-benzoylamino-4-methylbutyl methyl ketone, thick oil. *Benzoate oxime*, prisms and tables, *m.* 117–8°. *Oxime*, sirup. Reduced with Zn and HCl (*H*) yields α , β -dimethylpiperidine, b_{710} 138–40°. *Benzoate*, oil. *Hydrochloride* (*I*), fine needles. *Chloroplatinate*, long needles, *m.* 145° (decompn.) *Chloroaurate*, flat, pointed prisms, sinters 105°, *m.* 130–5°. *Mercuric chloride salt*, *m.* 211–2°. *Stannous chloride salt*, flat prisms or tables, *m.* 115–6°. *Picrate*, light yellow prisms, *m.* 147–8°. (*I*), distd. with Zn dust in a stream of H, gives α , β -dimethylpyridine (α , β -lutidine). *Hydrochloride*, very hygroscopic. *Chloroaurate*, feather-like crystals, *m.* 162–4°. *Chloroplatinate*, 6-sided prisms, *m.* 195°. *Mercuric chloride salt*, short, 3-sided prisms, *m.* 191–3°. *Picrate*, short prisms, *m.* 183–4°. On oxidation it yields quinolinic acid. δ -Phthalimido- α -methylvaleric acid, found in the oil after boiling the above acetate with HCl and extd. with Na₂CO₃ soln., white leaflets, *m.* 106–7°. It is not changed by heating with H₂O 2 hrs. at 175°. *Concd.* HBr at 190° decomp. it. *Calcium salt*, with 5 H₂O, leaflets or tables. Other by-products are α -methylhomopiperidinic acid, δ -amino- α -methylvaleric acid and β -methylpiperidone.

C. J. WEST.

Convallarin. I. J. LINDNER. Univ. Czernowitz. *Monatsh.* 36, 257–67(1915).—Contrary to the statements of Walz (*Neues Jahrbuch für Pharm.* 10, 145 (1858)) convallarin could not be obtained cryst.; the difficulty in obtaining a pure product lies not so much in removing the organic impurities as in the marked hygroscopic properties of the compd. Dried 2 weeks over CaCl₂ it analyzed for C₂₈H₄₀O₁₀, and probably is a hydrate with 1 H₂O. Samples dried at 100° indicate a partial decompn. of the hydrate. Upon sapon. with 2, 5 or 10% H₂SO₄ at about 100°, a hexose (glucose?) and convallaretin, C₁₅H₁₈O₄, are formed, hone-like crystals from alc. or Et₂O, darkens 75–80° but does not *m.* 225°. It readily forms a hydrate, C₁₅H₁₈O₄, which loses 1 mol. H₂O over P₂O₅ but not over CaCl₂. No MeO, CO nor double bond is present. It

gives a *diacetyl derivative*, amorphous, which indicates 2 HO groups. Convallaretin reacts with alkali, giving a *compound*, $C_8H_{14}O_8$, which indicates the presence of an ester group, $-CO_2CH_3-$.

C. J. WEST.

Perhalogenation of anthraquinone. ALFRED ECKERT AND KARL STEINER. Univ. Prag. *Monatsh.* 36, 269-80(1915); cf. *C. A.* 9, 1465.—1,2,4,5,6,7,8-*Heptachloroanthraquinone* (A) was prepd. by condensing 30 g. 1,2,4- $Cl_3C_6H_3$ and 15 g. $Cl_4C_6(CO)_2O$ by heating with 15 g. $AlCl_3$ 5 hrs. at 150° , which probably yields a mixt. of 2 isomeric *heptachlorobenzoylbenzoic acids*, yellow needles, m. $226-230^\circ$, and then heating 5 g. of this mixt. with 50 g. fuming H_2SO_4 1 hr. at 200° , extg. the product with hot H_2O and glacial AcOH and recrystg. from PhCl, pale yellow needles, m. 302° . Since this differs from the previously described compd., obtained from $C_6H_4(CO)_2C_6H_4$ and $SbCl_5$, the first compd. must be 1,2,3,5,6,7,8-*heptachloroanthraquinone* (B). Since 1,4,5,8- $Cl_2C_6H_3(CO)_2C_6H_3Cl_2$ (C) is formed as an intermediate product in the action of $SbCl_5$, the further action of $SbCl_5$ must result in a wandering of the Cl atom as well as in further chlorination. The action of 15 parts $SbCl_5$ upon (C) or (A) results in the formation of (B). (A) and (B) can be easily sep'd. as (A) is much more sol. in org. solvents than (B). *Heptabromoanthraquinone*, obtained by the action of 30 g. Br upon 10 g. $C_6H_4(CO)_2C_6H_4$ dissolved in 200 g. fuming H_2SO_4 at 50° , yellow needles from $PhNO_2$, does not m. 400° . If the reaction mixt. is heated 1 hr. on the H_2O bath after standing 4 hrs. in the cold, the product is decompd. into $Br_4C_6(CO_2H)_2$, C_6Br_6 , m. 306° , and *per-bromobenzoylbenzoic acid*, $Br_4C_6COCBr_4CO_2H$, needles from PhCl, m. 278° ; this is decompd. into $Br_4C_6(CO_2H)_2$ and $CHBr_3$ upon heating with 10 parts concd. H_2SO_4 1 hr. at $200-50^\circ$. *Pentabromobenzene*, needles from glacial AcOH or PhCl, m. 293° .

C. J. WEST.

Influence of the solvent upon the splitting off of carbon dioxide from dihydroxybenzoic acids. FRANZ V. HEMMELMAYR. Graz. *Monatsh.* 36, 299-302(1915); cf. *C. A.* 7, 1705.—Temp. does not play as much part as the solvent used. Salts, which only slightly increase the b. p. of H_2O , have a marked effect upon the decompn. Chlorides are more active than sulfates; using the same salt, the effect is nearly proportional to the salt content. Acids are more active than neutral salts, the effect depending upon the elec. dissociation of the acid (HCl acid is strongest, H_3PO_4 the weakest). Bases (except NH_4OH) have no effect. HO acids and phenols have no noticeable effect upon the decompn. H_3BO_3 appears to act as a retarding agent upon the splitting off of CO_2 .

C. J. WEST.

Isomerism of erucic, brassidinic and isoerucic acids. I. L. MASCARELLI. Univ. Cagliari. *Atti accad. Lincei* 23, II, 583-5(1914); *Gazz. chim. ital.* 45, I, 213-9(1915).—Three isomers of the acid $C_{22}H_{42}O_2$ are known; erucic acid (a) occurs as the glyceride in colza oil; brassidinic acid (b) is obtained from the preceding by the action of HNO_3 ; and isoerucic acid (c) is obtained by satg. erucic acid with HI and then splitting off HI with KOH. Fileti and Ponzio (*Gazz. chim. ital.* 1893, II, 382) have shown that in (a) the unsatd. bond occurs between the 13th and 14th C atom from the CO_2H group. This has been verified by treating (a) with Br and eliminating 2 HBr to get behenic acid, and by Yegorow (*C. A.* 7, 1477) through the hypoazotide. The formation of (b) from (a) is like the formation of elaidinic acid from oleic acid and shows that they are *cis* and *trans* forms. The existence of (c) is not provided for by the theory but according to Ponzio (*Gazz. chim. ital.* 1904, II, 50) the unsatd. bond is in the same position as in (a) and (b). M. has decided to study these 3 acids by physico-chem. methods. Sudborough and Gittens (*C. A.* 2, 1420) found the esterification consts. of (a) and (b) to be $K = 22.2$ and 22.5 , resp. Stewart (*C. A.* 1, 1406) found that the light absorption of maleic, fumaric, etc., differs for the geometric isomers but (S. et al., *J. Chem. Soc.* 101, 600(1912)) for (a) and (b) and (c) it is practically equal.

The refractive index is 105.00 for (a) and 105.02 for (b). It has been found that the magnetic rotation of the malenoid type is normal while that of the fumaroid type is high but the method was of no value in this case. The f. p. method is the most promising and is based on the fact that of 2 geometric isomers one makes solid solns. with the corresponding satd. compd. and the other does not. Bruni and Gocni (*Gazz. chim. ital.* 30, I, 55) showed in the case of *cis* and *trans* isomers, with ethylene bonds, that for any pair the *trans* form gives solid solns. in the corresponding satd. compd. but the *cis* does not. Further B. observed that the compds. with a double bond that give a solid soln. with the satd. deriv. have higher m. ps., are less sol. and more stable than the isomer that doesn't give the solid solns. and since fumaric ester belongs to the former group and maleic ester to the latter he concludes it is rational to assign the former to the fumaroid type and the latter to the malenoid type. II. L. MASCARELLI AND B. TOSCHI. *Ibid* 586-90.—The results on the cryoscopic behavior of (a), (b) and (c) are described. Of the 3 acids (a) is cryoscopically normal in behenic acid; (b) and (c) show mol. wts. higher than the theory. Accordingly assuming that the unsatd. bond is in the same position in all, (b) and (c) have a similar configuration. On the basis of B.'s deductions, (a) is the *cis* type and (b) and (c) *trans*. This conclusion is in agreement with the physical properties of the three acids: (b) has a higher m. p. and is more stable than (a). (a) was obtained as white pearly scales, m. 33-4°; (b) white scales, m. 57-60°; (c) cryst. powder, m. 52-3°; behenic acid, white, shining scales, m. 82-3°.

E. J. WITZEMANN.

Some nitrated and halogenated derivatives of pseudocumene. A. HUENDER. Univ. Amsterdam. *Rec. trav. chim.* 34, 1-34(1915).—*Trinitropseudocumene* and the substitution of one of its NO_2 groups with other radicals. 1,3,4- $\text{Me}_3\text{C}_6\text{H}_3$ (a), b. 167°, was nitrated according to Fittig and Laubinger (*Ann.* 151, 257) by adding 10 g. (a) drop by drop to a mixt. of 100 cc. concd. H_2SO_4 + 50 cc. HNO_3 (d. 1.52) with ice cooling. The mixt. poured into crushed ice, filtered, washed, dried and recrystd. from glacial AcOH gave trinitropseudocumene (b), m. 185° (yield $\approx 10\%$). 1 g. (b) in 50 cc. abs. MeOH treated with 0.2 g. Na in MeOH and warmed on the H_2O bath gave methoxydinitropseudocumene (c), colorless crystals, m. 80°. 0.20 g. (b) in 25 cc. abs. EtOH treated with 0.23 g. Na in EtOH , etc., gave, finally, a brown-black ppt. from which the EtO deriv. could not be sep'd. The presence of NaNO_2 was detd. so that NO_2 was substituted with OEt but the product was tarred. Lobry de Bruyn (*Rec. trav. chim.* 11, 112(1892); 13, 126(1894)) showed that NaOEt has stronger reducing properties than NaOMe . Solns. of (b) in AcMe treated with aq. NaOH form NaNO_2 but dinitropseudocumenol which should be formed could not be isolated. The products have not been examd. for acids derived by intramol. oxidation of Me by the NO_2 under the influence of NaOH . 1 g. (b) was heated 3 hrs. in the sealed tube at 120° with 20 cc. MeOH containing 0.140 g. NH_3 and gave on cooling orange-yellow needles of dinitropseudocumidine (d), m. 181°. This deriv. is not identical with that obtained by Auwers (*Ber.* 18, 662). (b) similarly treated with MeNH_2 for 10 hrs. on the H_2O bath gives 6-methylaminodinitropseudocumene (e), yellow crystals, m. 140°. Treated with HNO_3 (d. 1.52), (e) is converted into 6-methylnitramino-3,5-dinitropseudocumene, fine, colorless crystals, m. 113°. Attempts to replace an NO_2 in (b) with S and S_2 as was done by Blanksma (*Rec.* 20, 121(1901)) with $\text{C}_6\text{H}_4(\text{NO}_2)_2$ gave very little sulfide or disulfide because the SNa or SH was oxidized by the NO_2 . 1.26 g. 1,2,4- $\text{Cl}_3\text{C}_6\text{H}_3(\text{NO}_2)_2$ in EtOH + 1.5 g. $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ in EtOH soln. were filtered and treated with 1.6 g. (b) in EtO I and boiled; 2,3,5-trimethyl-4,6,2',4'-tetranitrodiphenyl sulfide (f), seps. in yellow crystals, m. 215°. The reaction is thus $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{Cl} + \text{Na}_2\text{S} \rightarrow (\text{NO}_2)_2\text{C}_6\text{H}_3\text{SNa} + \text{NaCl}$ and $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{SNa} + (\text{b}) \rightarrow (\text{f}) + \text{NaNO}_2$. *Prepn. of some nitro- and bromonitropseudocumenes.* After having found that one NO_2 in (b).

could be replaced variously, H. undertook to det. the constitution of the derivs. for this purpose because the m. ps. were so nearly identical. It was thought that the bromodinitro derivs. would be more satisfactory. One of these (probably 2,3,5,4,6-Me₃(O₂N)₂C₆Br) was obtained by treating (d) by Sandmeyer's reaction. A 2nd, probably 3,4,6,2,5-Me₃(O₂N)₂C₆Br, was obtained by direct bromination of (a) and subsequent nitration, but in repeating Kelbe and Pathe's expts. (*Ber.* 19, 1546(1886)) it became necessary to amplify the data on the Br and NO₂ derivs. of (a). 20 g. 5-pseudocumidine-HBr diazotized and poured into an HBr soln. of CuBr and distd. with steam gave the 5-bromopseudocumene (g) (15 g.) on adding NaOH. 25 cc. (a) + 0.001 g. Fe + Br₂ gives (g) besides other products. The oil obtained is freed from (g) by cooling to -25° and fractionated; crude 3-bromopseudocumene (h) (containing probably some of the 5- and 6-compd.) b. 226-30°. (b) treated with NH₄SH gives nitropseudocumidinesulfonic acid which at 130° in the sealed tube loses the SO₃H group to give 3-nitro-5-pseudocumidine, m. 136°, which diazotized, etc., gives 3-nitropseudocumene, m. 30°, and reduced with Fe + H₂SO₄ gives 3-aminopseudocumene, and which by Sandmeyer's reaction gives, finally, pure (h) as an oil. In order to obtain 6-bromopseudocumene 5-pseudocumidine was acetylated, then nitrated by boiling with 50% HNO₃ which gave 6-nitro-5-acetpseudocumidide. This sapond. (5 g.) with 20 cc. concd. H₂SO₄ at 120° in an oil bath and distd. from H₂O with steam gave the free base, m. 47°, from which NH₃ was eliminated to give 6-nitropseudocumene, m. 20°, b. 253°. This (10 g.) reduced with 25 g. Fe + H₂SO₄, finally, on the H₂O bath for 1.5 hrs. under a condenser, sepd. on cooling 6-pseudocumidine sulfate; the free base b. 233°. The free base by Sandmeyer's reaction gave 6-bromopseudocumene (i), b. 223°, m. -15°. (i) was more easily obtained thus: 5-pseudocumidine treated with concd. HCl sepd. the hydrochloride to which the calcd. amt. of Br₂ was added; the mixt. was heated 0.5 hr. on the H₂O bath and cooled. The crystals obtained were placed in Na₂CO₃ soln. and the mixt. distd. with steam; 6-bromo-5-pseudocumidine (j), m. 72°, was obtained. (j) was shown to have the Br at 6 by boiling it 0.25 hr. with Ac₂O, and pouring into H₂O, yielding the Ac deriv., m. 204°, which gave with HNO₃ (d. 1.52) 6-bromonitroacetopseudocumidine, m. 235°, which, sapond. with concd. H₂SO₄, gave the free base, m. 150°. (j) diazotized as above gave (i). The best yields were obtained by this method. Of the mono-NO₂ derivs. of (a) the prepn. of the 3- and 6-derivs. has been mentioned. The 5-NO₂ deriv. of (a) was obtained thus: 6.5 g. 5-pseudocumidine + 25 cc. H₂O + 8 cc. HNO₃ (d. 1.4) were cooled and treated with 7 g. NaNO₂ and the cold soln. was poured into a soln. of Cu₂O obtained by heating 50 g. CuSO₄ + 15 g. glucose + 100 cc. H₂O. Afterwards 20 g. NaOH in 60 cc. H₂O were added, cooled rapidly and AcOH added to slight acidity and the mixt. distd. with steam, giving crystals, m. 70°. A small amt. was nitrated further and gave (b), m. 186°. By prepg. the dinitropseudocumenes, H. was able to prove that in (b) the NO₂ group at 6 is the one substituted by NH₂, etc., in the reactions described in the beginning and that (d) is not identical with the deriv. obtained by Auwers. 40 g. 5-pseudocumidine was acetylated with 50 g. AcOH and the Ac deriv. added, 15 g. at a time, to a mixt. of 75 cc. HNO₃ + 75 cc. H₂SO₄, which gave 53 g. dinitroacetopseudocumidine, m. 228°, and which sapond. gave the free base, yellow crystals, m. 180°. 5 g. of the latter were dissolved in 30 cc. concd. H₂SO₄ + 15 cc. H₂O and treated with cooling with 2 g. NaNO₂ in 25 cc. H₂O. The whole was poured into 150 cc. boiling 95% EtOH, heated 10 min. and the EtOH distd. The 3,6-dinitropseudocumene (k) was distd. over with steam; it m. 96° (Nietzki, *Ber.* 27, 1429(1894)). The product (d) obtained by treating (b) with NH₃ was diazotized as described above and gave 3,5-dinitropseudocumene (l), m. 72°. (k) and (l) were reduced with (NH₄)₂S. (k) in EtOH soln. was treated with EtOH-NH₃ and H₂S was passed through the mixt. After boiling

0.5 hr., EtOH-NH₃ was added and H₂S passed through again for some hrs. Finally the EtOH was distd. off and the residue boiled with 5% HCl and filtered. On adding NH₄OH to the filtrate 5-amino-3-nitropseudocumene, m. 136°, identical with the product obtained from (b), was formed. Its constitution was proved (1) by melting it with the same compd. obtained by Mayer's method (*Ber.* 20, 966(1887)); (2) by adding Br in AcOH and obtaining 6-bromo-3-nitro-5-pseudocumidine, m. 150°; and (3) by diazotizing to obtain 3-nitropseudocumene, m. 30°. (k) was reduced in the same way for 12 hrs. and gave 3-nitro-6-aminopseudocumene, of which the constitution was proved by brominating in AcOH, giving 5-bromo-3-nitro-6-aminopseudocumene, m. 165°, and by boiling the diazotized compd. with EtOH to obtain 3-nitropseudocumene, m. 30°. The rule of Nölting, etc. (*Ber.* 35, 630(1902)) that NH₄SH in reacting on poly-NO₂ compds. attacks that NO₂ group first which has the least number of *o*-substituents was verified with (k) and (l). Also Clandish's rule (*J. Chem. Soc.* 87, 1257(1905)) that the more Me groups in the ring the more difficult and slow is the reduction of NO₂ was verified. The 5,6-dinitropseudocumene (m) was only obtained indirectly. 3-Pseudocumidine, b. 235°, was acetylated (Ac deriv., m. 187°) and nitrated in HNO₃ + H₂SO₄ to obtain 5,6-dinitroacetyl pseudocumidide, m. 221°. The Ac was sapond. off by heating with H₂SO₄ 0.5 hr. at 100° and pouring into H₂O; the free base, m. 206°, was diazotized, etc., and gave (n), yellow crystals, m. 90°. Of the dinitropseudocumidines, the 3,6,5-(NO₂)₃NH₂ deriv. (n), m. 181°, is known; the 3,5,6-(NO₂)₃NH₂ isomer (o), m. 180°, was obtained above from (b) with MeOH-NH₃; and the 5,6,3-(NO₂)₃NH₂ deriv., m. 206°, was obtained in the prepn. of (m). When (o) is acetylated with Ac₂O + a drop of H₂SO₄ the Ac deriv. of (o), m. 250°, was obtained; the Ac deriv. of (n), m. 228°. Of 6 possible isomeric mononitropseudocumidines 2 were mentioned above; 3-nitro-5-pseudocumidine, m. 136°, and 6-nitro-5-pseudocumidine, m. 47°. 3-Nitro-5-pseudocumidine, m. 92°, was obtained by reducing 3,6-dinitropseudocumene, and is distinguished by its 5-Br deriv., m. 165°, from the known 6-bromo-3-nitro-5-pseudocumidine, m. 150°. The dinitrobromopseudocumenes were obtained by nitrating the corresponding bromopseudocumene; 3,6-dinitro-5-bromopseudocumene (p), m. 218°; 5,6-dinitro-3-bromopseudocumene (q), m. 180°; 3,5-dinitro-6-bromopseudocumene (r), m. 179°, was obtained from the 6-NH₂ deriv. by Sandmeyer's reaction. The 3,5-dinitro-6-chloropseudocumene (s), colorless crystals, m. 162°, was obtained similarly. Although the NO₂ at 6 in (b) is easily replaced by OMe, NH₂ and NHMe it is more difficult to replace the Cl or Br at 6 by the above groups. In the case of (s) Cl is replaced by NH₂ by heating 3 hrs. in the sealed tube in EtOH-NH₃ at 120°, while (r) only reacts at 170°, which is in accord with the observations of Steger (*Rec. trav. chim.* 18, 9(1899)) and Lufok (*Ibid* 20, 324(1901)), viz., that the order of difficulty of replacement in the *o*- and *p*-position is: NO₂ is easier than Cl and Cl is easier than Br when all are in the same respective position. (p) heated 3 hrs. with 1 mol. NaOMe in MeOH at 120° is unchanged; at 170° tar is formed. (q) similarly treated also gives a negative result. Products of the reaction mixts. of HNO₃-H₂SO₄ on the halogendinitropseudocumenes. As was stated above, 5-bromopseudocumene heated in a mixt. of equal parts of HNO₃ (d. 1.52) + concd. H₂SO₄ gives white needles, m. 150° ((p) m. 216°). To assume that the Br has shifted its position does not help since the m. p. does not coincide with that of (q) or (s). The same product is more easily obtained by heating (p) with HNO₃-H₂SO₄ on the H₂O bath and the mixt. usually solidifies while heating. Poured into H₂O and recrystd. from AcOH, it m. 150°. This product is very different from (p) although it still contains Br. Unlike (p) an NO₂ group is easily replaced by OMe, becomes red and crystallizes with the NaNO₂ formed. The Cl analog of (p) gives a similar deriv., m. 147°. (r) gives a similar compound, colorless plates, m. 185°. On the contrary (b), trinitromesitylene, trinitro-

xylylene and trinitrotoluene are not affected by $\text{H}_2\text{SO}_4\text{-HNO}_3$. Likewise, (g) remains unchanged. The product obtained from (p) was analyzed with difficulty and found to be $\text{C}_8\text{H}_6\text{O}_4\text{N}_2\text{Br} + \text{NO}_2$, i. e., (p) with 1 H replaced by NO_2 which H. calls *the nitrate* (i), for short. (i) boiled with H_2O is not changed; in the sealed tube with H_2O it begins to react at 165° , becomes yellow, and seps. a colorless compd., m. 199° , and a yellow-red tablet. The latter remains unchanged when the treatment is repeated. 2 g. (i) in 15 cc. acetone and 15 cc. H_2O heated to 170° for 2 hrs. gave CO_2 , an acid soln. and the same cryst. compd., $\text{C}_8\text{H}_6\text{O}_4\text{N}_2\text{Br}$ (u), m. 202° . (u) is also obtained on boiling (i) with dil. H_2SO_4 at 145° . (i), m. 150° , becomes dark red 165° and then explodes, giving NO_2 vapors. When (i) is heated with mol. amts. of NaOMe and NaOEt or with MeOH-NH_3 and EtOH-NH_3 , resp., the same compd. (v), $\text{C}_8\text{H}_6\text{O}_4\text{N}_2\text{Br}$, m. 190° , is obtained. The latter reaction takes place at room temp. This compound is quite different from (u), especially in its solubility in H_2O and EtOH . 1 g. (i) in MeOH or $\text{EtOH} + 14$ drops of 33% MeNH_2 heated becomes red and seps. $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_4\text{Br}$, colorless, shining needles, m. 185° ; with EtNH_2 , $\text{C}_{11}\text{H}_{14}\text{N}_2\text{O}_4\text{Br}$, crystals, m. 130° , was sepd. The deriv. obtained with MeNH_2 dissolved in HNO_3 liberated N_2 and on diln. sepd. $\text{C}_8\text{H}_6\text{O}_4\text{N}_2\text{Br}$ (= (p) + O), colorless, m. 190° , showing NMe is replaced by O, probably identical with (v). 1.1 g. (i) boiled with 0.900 g. PhNH_2 seps. on cooling $\text{C}_8\text{H}_{14}\text{N}_2\text{O}_4\text{Br}$, golden crystals, m. 168° . From all the above it appears that (i) is (1) a compd. with an NO_2 group in the side chain, thus CH_2NO_2 , (2) an addition product of bromodinitropseudocumene, with HNO_2 , or (3) a nitrate of bromodinitropseudocumene, i. e., contains the group CH_2ONO_2 . Further work must det. which of these hypotheses is correct.

E. J. WITZEMANN.

Catalysis. Decomposition of heptachloropropane, $\text{CCl}_2\text{CCl}_2\text{CCl}_2\text{H}$, by heat and by the aid of catalyzers. J. BÖSEKEN, J. VAN DER SCHEER AND J. G. DE VOOGT. Delft. *Rec. trav. chim.* 34, 78-95 (1915).—Prins (*Thesis*, Delft, 1912) found that heptachloropropane (a) is decompd. by AlCl_3 into CHCl_3 and C_2Cl_4 and the 3 Cl derivs. seem to be in equil., thus: $\text{C}_2\text{HCl}_3 \rightleftharpoons \text{CHCl}_3 + \text{C}_2\text{Cl}_4$. But with AlCl_3 at 80° the vapor pressure, which should reach a limit, increases continually owing to the formation of HCl , so that $\text{C}_2\text{Cl}_3\text{H} \rightarrow \text{C}_2\text{Cl}_4 + \text{HCl}$ must also take place. This paper is a report on further work on these reactions. (a) was drawn by means of a current of CO_2 through a glass tube passing through an electric furnace. The temp. was regulated and detd. with a Pt-Ir couple. The tube was charged with fragments of Cu_2Cl_2 , ZnCl_2 , BaCl_2 , etc. The products passed through a flask fitted with a return-flow condenser and passed from the latter into an ice-cooled receiver and thence through a wash bottle to remove HCl . From the HCl titration the amt. of C_2Cl_4 is calcd. according to the reaction: The comp. of the mixt. of Cl derivs. condensed ($\text{C}_2\text{Cl}_3\text{H}$, C_2Cl_4 , CHCl_3 and C_2Cl_4) was detd. by titrating with NaOEt in the known way. Of all these, (a) decomp. very quickly and quant., thus: $\text{C}_2\text{Cl}_3\text{H} + \text{KOH} \rightarrow \text{KCl} + \text{H}_2\text{O} + \text{C}_2\text{Cl}_4$, but precautions are necessary since $\text{C}_2\text{Cl}_4 + 3\text{KOEt} \rightarrow 3\text{KCl} + \text{C}_2\text{Cl}_3\text{C(OEt)}_2$ more slowly. By detg. the amt. of KOH quickly utilized and stopping the addition when KOH is only slowly neutralized (a) can be quant. detd. as is shown by control analyses. The error in titration is about 1% but the error due to volatility is greater. The HCl formed was detd. (owing to the CO_2 present) by adding Ba(OH)_2 in excess, then H_2SO_4 of a known titer and the excess titrated back after boiling with the acid. 15 expts. with various amts. of (a) at temps. ranging from 240° to 420° in the empty tube showed from 1.3 to 62.3% decompd. to give $\text{C}_2\text{Cl}_4 + \text{HCl}$. The reaction giving $\text{CHCl}_3 + \text{C}_2\text{Cl}_4$ did not occur as was shown by detg. the unchanged (a). There was a small discrepancy in the last expt. The quantity of (a) used and the duration of the expt. have little influence on the reaction. In 11 expts., using ZnCl_2 as a catalyst and ranging from 260° to 410° , 20.8 to 89.7% decompd. to give $\text{C}_2\text{Cl}_4 + \text{HCl}$. The total decompn. was nearly

the same in each case. This shows that ZnCl_2 accelerates this decompn. but does not activate the breaking of the C union to give $\text{CHCl}_3 + \text{C}_2\text{Cl}_4$. Its effect is relatively greater at the lower temps. With BaCl_2 for the same range of temps. a very feeble positive effect was obtained. In the mono-Cl and -Br derivs. the mol. is highly unsatd. after the HCl is sepd. and has enough affinity so that the bibasic chlorides play an important rôle in their catalysis, but with (a) the residue C_2Cl_4 is much less satd. and a chloride with more pronounced affinities must be used. Expts. with Cu_2Cl_2 showed: (1) that the decompn. is much more complete than in the preceding expts.; at 190° the (a) was 37% dissociated; at 250° only 10% remained unchanged and all was decompd. at 400° ; (2) the decompn. goes in 2 directions; (3) although the figures are irregular they show that the decompn. into $\text{C}_2\text{Cl}_4 + \text{CHCl}_3$ is more active than the decompn. into $\text{HCl} + \text{C}_2\text{Cl}_6$, especially at high temps. Attempts to obtain (a) by boiling $\text{CHCl}_3 + \text{C}_2\text{Cl}_4$ with Cu_2Cl_2 failed so that it seems that Cu_2Cl_2 does not become active at a sufficiently low temp., and moreover it is not so sol. as AlCl_3 . AlCl_3 , however, is active at a temp. at which the equil. in $\text{C}_2\text{Cl}_4 + \text{H} \rightleftharpoons \text{CHCl}_3 + \text{C}_2\text{Cl}_6$ is far to the left and the decompn. into $\text{C}_2\text{Cl}_4 + \text{HCl}$ is of secondary importance. The system $\text{C}_2\text{Cl}_4 + \text{H}$, C_2Cl_6 , C_2Cl_4 , CHCl_3 , HCl and AlCl_3 . $\text{C}_2\text{Cl}_4 + \text{CHCl}_3$ at 65° gives a yield of 9% of (a) with AlCl_3 which shows that the equil. is nearly completely on the side of (a). In order to study this complicated system from 65 – 200° , 0.5–1 g. (a) + about 0.1 g. AlCl_3 were sealed in small tubes and heated to the proper temp. in an oil bath. The unchanged (a) was detd., the C_2Cl_4 was detd. approx. in CCl_4 soln. by treating with excess of Br in the light and titrating the excess of Br. C_2Cl_6 is not affected much. The contents of the tubes was dissolved in CCl_4 , this soln. washed with H_2O until neutral, and the washings extd. with CCl_4 to win back dissolved Cl derivs. This soln. is divided in 2 parts and analyzed. 3 expts. at 110° and 120° and 2 at 130° for various time intervals were made. The results show that at 110° the equil. $\text{C}_2\text{HCl}_7 \rightleftharpoons \text{C}_2\text{Cl}_4 + \text{CHCl}_3$ is considerably to the right, in the 50-hr. expt. (63.4%), while 34.4% goes to $\text{C}_2\text{Cl}_6 + \text{HCl}$. The velocity of this latter reaction increases until at 130° 90.5% goes this way and only 9.1 to $\text{C}_2\text{Cl}_4 + \text{CHCl}_3$. The decompn. into $\text{C}_2\text{Cl}_6 + \text{HCl}$ is probably not reversible. On satg. C_2Cl_6 with HCl and heating at 110° with AlCl_3 not a trace of (a) was formed. Equimol. amts. of C_2Cl_4 and CHCl_3 were heated with AlCl_3 from 70° to 108° . When there is no excess of CHCl_3 the synthesis is very slow even at 65° ; an increase in temp. accelerates it very markedly but at the same time the decompn. into $\text{C}_2\text{Cl}_6 + \text{HCl}$ appears, so that at 108° less (a) is formed than at 100° . So that to prep. (a) a temp. as low as possible and an excess of CHCl_3 are necessary. AlCl_3 is appropriate for the catalytic synthesis of (a) because all the compds. CHCl_3 , C_2Cl_6 and C_2Cl_4 are activated at the temp. at which the equil. $\text{C}_2\text{Cl}_4 + \text{CHCl}_3 \rightleftharpoons \text{C}_2\text{Cl}_7\text{H}$ is on the side of $\text{C}_2\text{Cl}_7\text{H}$. The decompn. and synthesis of (a) with AlCl_3 shows: (1) that the equil. $\text{C}_2\text{Cl}_4 + \text{CHCl}_3 \rightleftharpoons \text{C}_2\text{Cl}_7\text{H}$ is displaced toward the left at 110° ; (2) that the decompn. into $\text{C}_2\text{Cl}_6 + \text{HCl}$ at 110° is not a reversible reaction; (3) that the 1st reaction is more active than the 2nd at 65° , while the equil. itself is probably considerably to the right; that the equil. in (1) is not able to be realized because of the reaction in (2).

E. J. WITZEMANN.

The influence of some glycols on the electrical conductivity of boric acid. J. BÖSEKEN, *et al.* Delft. *Rec. trav. chim.* 34, 96–113 (1915).—Since the 1st communication on this subject (*C. A.* 6, 623) a series of glycols have been examd. α -Monochlorohydrin (a), b. 135 – 40° , was neutralized with Na_2CO_3 , and fractionated again. The N aq. soln. showed a sp. cond. of 29.1×10^{-4} which quickly rose to 31.7×10^{-4} . Freshly prepd. (a) dissolved in 1 and 0.5 mol. concns. in 0.5 mol. solns. of H_3BO_3 (cond. 26.8×10^{-4}) showed a very small difference in cond. as compared with the calcd. value, showing that no compd. with a higher cond. is formed between (a) and H_3BO_3 .

Divinylglycol (b) (Griner, *Ann. chim. phys.* [6] 26, 369(1892)), b. 138–44°, used in fresh solns. like (a) and H_2BO_3 showed a feeble positive influence on the calcd. cond. of the mixt. The solns. of (b) become acid on standing. Pinacol in 0.25 mol. soln. at 25° has a cond. of 8.1×10^{-8} , but in 0.25 mol. solns. of H_2BO_3 it showed little tendency to form a complex. 1,3-Propanediol (Nef, *Ann.* 335, 206, 306(1904)), b. 214°, was redistd. from BaO ; the cond. of a *N* soln. is 2×10^{-8} , which mixed with 0.5 mol. H_2BO_3 shows a slight depression, which excludes the formation of a complex. 1,4-Butanediol (Bouveault, Blanc, *Bull. soc. chim.* [3] 31, 1210(1904)), b₇₆ 235°, shows no tendency to form a complex acid with a higher cond. According to the Baeyer strain theory the 2 OH's are close enough together so that they might be expected to have some effect. α -Monophenyl glyceryl ether (c), $PhOCH_2CH(OH)CH_2OH$, obtained from phenylglycide (Lindemann, *Ber.* 24, 2245(1891)) by boiling it with twice its wt. of 2 *N* H_2SO_4 and extg. with Et_2O , etc., b₄₀ 213°, m. 67°. With H_2BO_3 no complex with a larger cond. is formed. B. finds confusion in the literature on the products formed by the action of $PhONa$ on $ClCH_2CH_2CH_2O$ by which (d) and $(PhOCH_2)_2CHOH$ (e) are formed.

Some physical consts. and the action of Br on these derivs. were studied. Of (d) the mol. wt. in $PhOH$ is 148.8 (calcd. 150), $d_4^{21.2}$ 1.1109, n_D^{21} 1.53072, mol. refraction 41.598 (calcd. 41.246). Of (e) the mol. wt. in $PhOH$ is 214 (calcd. 244), m. 81°, d_4^{24} 1.179, av. mol. refraction in $EtOH$ or $MeOH$, 69.45 (calcd. 69.077). Of (c) the m. p. is 69°, d_{40} 1.225, mol. refraction 44.61. In order further to det. their individuality their behavior toward Br was studied. $PhOH$ in either H_2O or CCl_4 soln. treated with Br 15 min. or 5 hrs. absorbed 3 atoms of Br per mol. $PhOH$. (d) similarly treated in CCl_4 soln. for 15 min. absorbed ≈ 1 atom of Br; (c) in H_2O or CCl_4 for 15 min. absorbed ≈ 2 atoms Br; (e) in CCl_4 for 15 min. or 5 hrs. absorbed ≈ 2 atoms Br. The results show clearly that (d) and (e) are markedly different. It is interesting to note that the substitution of glycide for OH cuts down the rapid substitution in the Ph group from 3 to 1. In (e) it is almost certain that 1 Br enters each nucleus, but in (c) 2 Br atoms react, showing that the free OH's influence this substitution favorably. *Bisbromophenyl glyceryl ether* (probably p - $BrC_6H_4OCH_2CH_2CHOH$) was obtained as white leaves, m. 81.5°, is stable in 20% $NaOEt$ soln., is attacked and tarred by $AlCl_3$. The *dibromophenyl glyceryl ether*, probably o,p - $Br_2C_6H_3OCH_2CH(OH)CH_2OH$, is obtained as white crystals, m. 90.5°. None of the glycols examd. increases the cond. of H_2BO_3 solns.; glycerol shows a weak positive effect; Magnanini has shown that erythritol, mannitol and dulcitol show a marked positive effect. B.'s earlier expts. showed that pyrocatechol and pyrogallol have a marked positive effect but that resorcinol, quinol and phloroglucinol have no or a negative effect on the cond. So that it is clear that: (1) OH groups repel each other; (2) polyatomic alcs. form compds. with a high cond. when 2 OH groups are in a favorable position; (3) the position will be favorable when the OH groups are in the same plane and on the same side of the 2 C atoms to which they are bound and thus rings like $O.C.C.OBOH$ and $O.C.C.C.O.-$

BOH are formed. In the simple glycols the OH groups repel each other and get as far apart as possible and thus the complex is not formed, but as the OH's are multiplied they can not place themselves so unfavorably and so complexes are formed. 1,3-Propanediol does not react with H_2BO_3 but the homologous pentaerythritol does because it has more OH's. $CNO_2(CH_2OH)_4$ (Henry, *Rec. trav. chim.* 21, 210), m. 155–60°, showed an excess cond. of 122.2×10^{-8} in 0.5 mol. soln. when mixed with 0.5 mol. H_2BO_3 . The excess cond. for 0.5 mol. pentaerythritol is 221.9×10^{-8} ; for glycerol 8.3×10^{-8} . Sorbitol (obtained by reducing glucose, Fischer, *Ber.* 23, 2133(1890)) shows a very marked effect on the cond.; it is much stronger than that of pyrogallol. The max. cond. observed on mixing 0.5 mol. solns. of sorbitol and H_2BO_3 was $1303 \times$

10^{-8} (calcd. 48.3×10^{-8}), i. e., an excess cond. of 1254.7×10^{-8} , due to the formation of an acid complex.

E. J. WITZEMANN.

The coloring of certain picrylmethylamine derivatives by alkalis. A. P. N. FRANCHIMONT AND H. J. BACKER. *Verslag Akad. Wetenschappen* 23, 641-6(1914).—The results of the measurements described in a former paper (C. A. 8, 1271) on the absorption spectra of picrylmethylnitroamines and their alkaline solns. have an important bearing on the theory of Hantzsch that their coloring may be ascribed to the action of the NO_2 - and NH_2 -groups on each other and that the coloring is thus detd. by the NO_2 -groups of the C_6H_2 nucleus which react with the base, while the NO_2 -groups bound to N play only a subsidiary rôle. In order to test this theory more completely, observations were made on the absorption spectra of various derivs. of picrylmethylamine of the form Picr.NMeX, in which X = Ac, CO_2Me , CO_2Et , Ph or NO. The spectra for these compds. and their alk. solns. are shown graphically and confirm completely the above theory.

L. H. ADAMS.

α -Sulfofropionic acid and its separation into optically active isomers. A. P. N. FRANCHIMONT AND H. J. BACKER. *Verslag Akad. Wetenschappen* 23, 647-52(1914).—To obtain the *d*-form of α -sulfofropionic acid an aq. soln. of its acid strychnine salt was allowed to cryst., and the product converted into the neutral Ba salt by treatment with the theoretical amt. of $\text{Ba}(\text{OH})_2$. The Ba was then removed by addition of the theoretical amt. of H_2SO_4 to a soln. of the Ba salt, and the α -form obtained finally by recrystn. over P_2O_5 . It contains 1 mol. H_2O of crystn. and is very hygroscopic, m. $81-2^\circ$, $[\alpha]_D^{20}$ 32° , $[\text{M}]_D^{20}$ 49.2° ; acid K salt, α 23.8° , M 45.7° ; acid Ba salt, α 18.0° , M 79.8° ; acid strychnine salt, α -14.6° , M -71.4° ; neutral Ba salt, α -4.96° , M -14.4° . The *l*-form was prepd. in a similar way from the mother liquors from which the acid strychnine salt of the *d*-form had been sepd. It also contains 1 mol. H_2O of crystn.: its m. p. was not detd.; α -29.8° , M -45.8° ; acid strychnine salt, α -27.7° , M -135° ; neutral NH_4 salt, α 7.9° , M 14.8° . The racemic acid (1 mol. H_2O of crystn.), m. 100.5° .

L. H. ADAMS.

Chondroitin-sulfuric acid. IV. P. A. LEVENE AND F. B. LAForge. Rockefeller Inst. *J. Biol. Chem.* 20, 433-44(1915); cf. C. A. 8, 2704.—Chondrosamine, the hexosamine obtained by hydrolyzing chondroitine- H_2SO_4 , contains a normal C chain, as it is oxidized by Br to tetrahydroxyaminocaproic acid, which on reduction yields a monohydroxyaminocaproic acid, identical with that obtained from glucosaminic acid under the same conditions. On oxidation of desaminochondrosamine with HNO_3 , a di- CO_2H acid, chondrosic acid, is formed which analyzes for an anhydrotetrahydroxyadipic acid and is isomeric with isosaccharic acid. An O bridge is present between the α - and α_1 -C atoms. The osazone of chondrosamine is identical with that obtained from allose or altrose and chondrosamine apparently has the structure *l*- α -allosamine. No evidence has yet been obtained as to the arrangement of the groups on the α -C atom in the original sugar. Chitaric and chitonic acids are probably epimers, one having the configuration of glucose and the other of mannose. *Chondrosaminic acid*, from chondrosamine-HCl by the action of excess of Br, short, prismatic needles grouped in rosettes; does not melt but darkens above 190° ; $[\alpha]_D^{25.6}$ -16.15° , after 48 hrs., -29.23° . *Chondrosic acid* was obtained by boiling the Ca salt previously described (C. A. 8, 2704) with $(\text{CO}_2\text{H})_2$; large parallelopipeds, m. $179-81^\circ$; $[\alpha]_D^{28}$ -16.56° . *Chondrosaminic acid*, after deamination with AgNO_3 , on oxidation with HNO_3 yielded inactive *epichondrosic acid*, m. $201-2^\circ$. A very small amt. of hexosaminic acid was obtained by the action of 80% HCN on ribosimine, m. 198° (decompn.), $[\alpha]_D^{28}$ -22.26° , after 48 hrs., -9.4° . The acid K salt of epi-isosaccharic acid was prepd. by the oxidation of deaminized glucosaminic acid and from it the Pb salt was obtained, which on decompn. with H_2SO_4 gave free *epi-isosaccharic acid*, large plates, very sol. in

the usual reagents except cold amyl alc. and Et_2O . It contains 1 mol. H_2O which can be removed by heating *in vacuo* at 78° ; the dry substance m. 160° , $[\alpha]_D^{25}$ 39.7° .

A. P. LOTHROP.

The mutarotation of phenylosazones of pentoses and hexoses. P. A. LEVENE AND F. B. LAForge. Rockefeller Inst. *J. Biol. Chem.* 20, 429-31 (1915).—In working with rare sugars the identification of osazones is of much importance. In Neuberg's $\text{C}_6\text{H}_5\text{N}$ -EtOH soln. the initial rotation of an osazone is affected slightly by the presence of impurities but the direction of the mutarotation and the equil. rotation remain const. The m. ps. of the osazones, at a rate of heating of 4-5 sec. per 1° , have been revised and are as follows: *l*-arabinose, 166° ; *d*-xylose, 164° ; altrose, 178° ; gulose, 168° ; galactose, 201° ; glucose, 208° . Optical rotations: *d*-xylosazone, $[\alpha]_D$ -0.10° , after 24 hrs., -0.43° ; *l*-arabinoxazone, 0.55° , after 18 hrs., 0.30° ; *d*-altrosazone, -0.40° , after 24 hrs., -0.29° ; *d*-gulosazone, 0.07° , after 24 hrs., 0.50° ; *d*-galactosazone, 0.80° , after 24 hrs., 0.34° ; *d*-glucosazone, -0.62° , after 24 hrs., -0.35° . A. P. LOTHROP.

The elimination of bromine from dibromoanisylideneacetophenone. I. F. J. WILSON AND A. A. BOON. *Pharm. J.* 94, 486-7 (1915).—The compd. $\text{MeOC}_6\text{H}_4\text{CHBr}\cdot\text{CHBrBz}$, m. $139-40^\circ$, loses HBr by treatment with abs. MeOH or EtOH, forming either $\text{MeOC}_6\text{H}_4\text{CHBr}\cdot\text{CH(OR)Bz}$ or $\text{MeOC}_6\text{H}_4\text{CH(OR)CHBrBz}$ ($\text{R} = \text{Me}$ or Et). MeO compd., m. 102° , EtO compd., m. $74-5^\circ$. II. Cf. *J. Am. Chem. Soc.* 22, 667-71 (1900).—Removal of HBr from the dibromide with formation of $\text{MeOC}_6\text{H}_4\text{CBr}\cdot\text{CHBz}$ or $\text{MeOC}_6\text{H}_4\text{CH}\cdot\text{CBrBz}$, m. $93-4^\circ$, can be effected by the action of either (a) $\text{C}_2\text{H}_5\text{OH}$, (b) *iso*- $\text{C}_4\text{H}_9\text{OH}$, (c) PhCH_2OH or (d) AcOH. A mixt. of 20 g. Br_2 compd. with excess of pure reagent was heated on the H_2O bath for 1-3 hrs. and the products were fractionated. $\text{C}_2\text{H}_5\text{Br}$ and $\text{C}_4\text{H}_9\text{Br}$ were among the by-products of (a) and (b), resp. III. Elimination of both Br atoms from the dibromide was effected, with formation of $\text{MeOC}_6\text{H}_4\text{CH}\cdot\text{CHBz}$, m. $75-6^\circ$, by boiling on the H_2O bath with excess of (e) Me_2CHOH , (f) Me_2COH , (g) Me_2CO , (h) benzoin. With (g), heating lasted 1 hr., with (e), (f), and (h) 7-8 hrs. Of by-products, only Me_2CHBr and Me_2CBr were indicated in (e) and (f), resp. Much resin formed in (II) and (III). S. W.

Oxypinenes. J. EMILE BLOMÉN. *Am. J. Pharm.* 87, 199-210 (1915).—A review of the literature with the following summary: (1) When pinene or turpentine is oxidized by the air, O_3 is absorbed from the air, either as such, or O_2 is, partly at least, transformed into O_3 . (2) When pinene is directly oxidized by O_3 , one or more ozonides of pinene will result. (3) When either of the above ozonides of pinene comes into contact with moisture a decompn. takes place, resulting in the formation of H_2O_2 and the intermediary O compds. of pinene (oxypinenes). (4) On prolonged standing or by heat intermol. or auto-oxidation will take place, resulting in the higher oxidation products of pinene—pinonic acid, etc.

W. G. GAESSLER.

The alkaloids in tobacco extract. EUGEN NOGA. *Fach. Mitt. Tabakregie* 1914, Nos. 1 and 2; *Chem. Zentr.* 1915, I, 434.—Turkish tobacco was digested with H_2O and the liquor evapd. *in vacuo*. By shaking out with C_6H_6 there was obtained from 25 kg. ext. of 40° Bé. a small amt. of alkaloid not volatile in steam. This was fractionated into 4 parts: (1) *Nicotoline*, $\text{C}_8\text{H}_{11}\text{N}$, a colorless, mobile liquid of strong, characteristic odor, similar to that of $\text{C}_8\text{H}_9\text{N}$, b. 208° , d_4^{21} 0.9545, n_D^{20} 1.5105; it gives the common alkaloid reactions. With HCl, H_2SO_4 , picric acid, HgCl_2 and PtCl_4 , it forms well crystd. salts of definite m. p. (2) *Nicotine*, b. 267° (Pictet and Rotschy). (3) *Isonicotine*, $\text{C}_8\text{H}_{11}\text{N}$, a colorless, thick, oily liquid, of rather strong and very persistent odor, b. 293° , becoming dark, d_4^{20} 1.0984, n_D^{20} 1.5749; it is optically inactive, easily sol. in org. solvents, difficultly in H_2O and petr. ether. It forms well crystd. salts with HCl, H_2SO_4 , picric acid, HgCl_2 , PtCl_4 , AuCl_3 and with MeI. It is oxidized to nicotinic acid,

gives the pine splint reaction and immediately decolorizes KMnO_4 in the cold. These

properties indicate the formula $\begin{array}{c} \text{CH}:\text{CH}:\text{C}=\text{C}:\text{CH}:\text{CH}_2 \\ || \quad | \quad | \quad | \\ \text{CH}:\text{N}=\text{CH} \quad \text{NMe}-\text{CH}_2 \end{array}$. (4) Nicotelline, $\text{C}_{10}\text{H}_8\text{N}_2$,

m. 148° , b. above 300° (Pictet).

E. H.

The isomeric octa-acetates of lactose. C. S. HUDSON AND J. M. JOHNSON. *J. Am. Chem. Soc.* 37, 1270-5 (1915).—To 400 cc. of Ac_2O and 25 g. NaOAc heated nearly to boiling 100 g. com. milk sugar is slowly added (after the reaction has started, it continues without external heating); when all the sugar has dissolved the soln. is boiled 10 min. and poured into much cold H_2O , the viscous ppt. stirred, allowed to settle, the H_2O poured off and fresh portions added from time to time; after standing under H_2O overnight, the solid mass is filtered, dried, exhausted with warm Et_2O by decantation and the residue recrystd. from 95% alc. until the sp. rotation is const.; yield, 55%. Under the microscope, each minute crystal can be seen to melt distinctly about 90° , but the melt is so viscous that the drops do not coalesce, and as the temp. rises to 100° , air bubbles appear and give a whitish appearance which does not disappear till about 104° as the liquid becomes more fluid. $[\alpha]_D^{20}$ for this lactose β -octa-acetate ($c = \text{g. per } 100 \text{ cc. soln.}$): CHCl_3 , -4.70° , -3.45° for c 10.3644, 19.4414, resp.; C_6H_6 , -25.78° , -23.52° for c 5.72, 10.49; glacial and 50% AcOH , no perceptible rotation for c 10. When 50 g. of this acetate and 5 g. ZnCl_2 in 250 cc. Ac_2O are heated 30 min. on the H_2O bath, cooled, poured into much H_2O , allowed to stand overnight, filtered, ground, dried in the air, crystd. from Et_2O and then repeatedly from 95% alc., there is obtained a 56% yield of an isomeric lactose α -octa-acetate, felted needles, m. 152° ; $[\alpha]_D^{20}$ 53.62°, 54.77° for c 7.8560, 20.3340 in CHCl_3 ; 23.89°, 28.6° for c 4.7518, 10.66 in C_6H_6 ; 60.72°, 59.93° for c 6.0932, 9.8868 in glacial AcOH ; 61.40° for c 4.9356 in 50% AcOH . Solns. of 2.5 g. of either isomer in 50 cc. glacial AcOH containing ZnCl_2 kept 5 months at 20° attain equil. when about 86% of the α -form is present; 5 g. of either isomer and 0.5 g. ZnCl_2 in 50 cc. Ac_2O kept 30 min. at 100° , reach equil. with 81% of the α -form present. With HBr in Ac_2O - AcOH , both yield the same hepta-acetyl-bromolactose, m. $139-41^\circ$, $[\alpha]_D^{20}$ 104-5° in CHCl_3 (Fischer, *C. A.* 4, 3234). The α -form gives an av. mol. wt. of 692 in freezing C_6H_6 , the β -form 611. The more strongly d -rotatory form is called α , like the more strongly d -rotatory lactose. The algebraic difference of the mol. rotations of the 2 forms agrees closely with that of the 2 glucose penta-acetates in CHCl_3 and 50% and glacial AcOH but not so closely in C_6H_6 (cf. preceding abstr.).

CHAS. A. ROUILLER.

The isomeric alpha- and beta-octa-acetates of maltose and of cellose. C. S. HUDSON AND J. M. JOHNSON. *J. Am. Chem. Soc.* 37, 1276-80 (1915); cf. preceding abstr.—The previously known β -maltose octa-acetate m. $159-60^\circ$ (cor.): $[\alpha]_D^{20}$ 62.59°, 62.91° for c 5.09, 10.61 in CHCl_3 ; 74.83°, 74.52° for c 5.20, 10.26 in C_6H_6 ; 54.80° 57.40° for c 5.45, 10.43 in 99.5% AcOH . From 100 g. heated 11 min. on the H_2O bath in 250 cc. Ac_2O with 5 g. ZnCl_2 is obtained the α -maltose octa-acetate, m. 125° (cor.): $[\alpha]_D^{20}$ 122.77°, 121.94° for c 5.01, 9.94 in CHCl_3 ; 124.05°, 123.11° for c 5.00, 9.93 in C_6H_6 ; 124.25°, 124.50° for c 3.95, 10.12 in 99.5% AcOH ; 121.24°, 120.25° for c 5.06, 10.07 in MeOH . α -Cellose octa-acetate, prepd. in the usual way from filter paper with Ac_2O and a little concd. H_2SO_4 and recrystd. from 95% alc. until the rotation is const., shows $[\alpha]_D^{20}$ 41.95°, 40.87° for c 9.85, 5.85 in CHCl_3 , and m. 229.5° (cor.). When this is hydrolyzed with alc. KOH and 75 g. of the resulting cryst. cellose is acetylated with Ac_2O and NaOAc , there is obtained 111 g. octa-acetate with $[\alpha]_D^{20}$ -7.5° in CHCl_3 ; after 16 crystns. from alc., alc.- CHCl_3 and CHCl_3 - Et_2O , this gives 19 g. m. 202° (cor.), $[\alpha]_D^{20}$ -14.48° , -14.74° for c 10.88, 5.10 in CHCl_3 ; 2.96 g. of this, heated 15 min. on the H_2O bath in 50 cc. Ac_2O with a trace of ZnCl_2 , gives 1.9 g.

of the α -compd., $m. 221-3^\circ$, $[\alpha] 40.5^\circ$. The rotary power of the transformed soln. (44.9°) shows that the equil. is far towards the side of the α -form. The formation of the α -acetate with Ac_2O and H_2SO_4 from cellulose, also, does not show whether cellulose is a condensation product of α - or β -cellulose. The algebraic differences of the mol. rotations in $CHCl_3$ of the acetates of the α - and β -forms of glucose, lactose, maltose and cellose all agree closely, showing that the differences in structure in the 4 acetylated sugars do not appreciably affect the rotatory power of the end asym. C atom; this may be somewhat due to the fact that the 3 bioses are derivs. of glucose and have much of their structure in common with glucose. CHAS. A. ROUILLER.

The isomeric penta-acetates of mannose. C. S. HUDSON AND J. K. DALE. *J. Am. Chem. Soc.* 37, 1280-2 (1915).— β -Mannose penta-acetate, $m. 117-8^\circ$ (cor.), $[\alpha]_D^{20} -25.3^\circ$, -25.1° for c 8.4292, 18.136 in $CHCl_3$, is obtained in 45-50% yield from 10 g. mannose slowly added to 4 g. $ZnCl_2$ in 40 g. Ac_2O kept at 0° with occasional shaking for 24 hrs. With 30 cc. Ac_2O containing 1 g. $ZnCl_2$ on the H_2O bath for 30 min., 20 g. yields 7 g. of the isomeric α -penta-acetate, $m. 64^\circ$ (cor.), $[\alpha]_D^{20} 54.9^\circ$ for c 3.6788 in $CHCl_3$. The difference in the mol. rotations of the 2 forms (31,300) is considerably smaller than the corresponding value for the glucose penta-acetates (38,100), which suggests that the change from the glucose to the mannose chain may somewhat affect the rotation of the end asym. C atom. CHAS. A. ROUILLER.

Crystalline d -fructose penta-acetate. C. S. HUDSON AND D. H. BRAUNS. *J. Am. Chem. Soc.* 37, 1283-5 (1915).—To 240 cc. Ac_2O and 10 cc. concd. H_2SO_4 kept in ice and salt and vigorously stirred is slowly added 40 g. d -fructose; when the sugar has dissolved (about 1 hr.), the mixt. is shaken with 500 cc. ice H_2O , neutralized with $NaHCO_3$, filtered and washed with $CHCl_3$ and the filtrate also extd. with $CHCl_3$; the $CHCl_3$ solns. are dried with $CaCl_2$ and concd. *in vacuo* to 30-50 cc., spread in a thin layer in a flat dish and a strong current of air passed over them till the odor of the $CHCl_3$ disappears and that of Ac_2O becomes noticeable; the residue, kept *in vacuo* near KOH and occasionally stirred, crysts. to a solid mass which, when stirred in a mortar with Et_2O and filtered, yields 16 g. of pure penta-acetate, sepg. from Et_2O on slow evapn. in large crystals. $m. 108-9^\circ$, from C_6H_6 in crystals with 1 mol. of solvent, $m. 90^\circ$; $[\alpha]_D^{20} -120.9^\circ$ and 105.5° for c 5.000 in $CHCl_3$ and c 2.000 in C_6H_6 , resp. CHAS. A. ROUILLER.

The volatile oils of the genus *Solidago*. EMERSON R. MILLER AND JEMISON M. MOSELEY. *J. Am. Chem. Soc.* 37, 1285-94 (1915).—Steam distn. of fresh *Solidago rugosa* Mill., in full bloom, collected near Auburn, Ala., gave about 0.4% of a light yellow oil, $d_4^{25} 0.8620$, $[\alpha]_D -12.8^\circ$, $n_D^{25} 1.4813$, sapon. no. 4.22, sapon. no. after acetylation 10.97, corresponding to 1.47% ester calcd. as borneol acetate and 1.67% free alc. calcd. as borneol. Fractionation after sapon. gave chiefly a fraction having all the properties of α -pinene, together with fractions which were undoubtedly limonene and β -pinene. Similarly, *S. odora* Ait. generally gave about 1% of oil with a rotation of $10-20^\circ$ in a 100 mm. tube; the mixt. of oils from several distns. was slightly yellow, with an odor somewhat like that of anise and with a suggestion of saffrole and a warm and sweetish taste, $d_4^{25} 0.9310$, $[\alpha]_D 13.72^\circ$, $n_D^{25} 1.5065$, sapon. no. 7.9, acid no. 0.63, % of MeO 15.9. The oil (0.65% yield) obtained from plants which had been transplanted and cultivated in an open field and harvested about Sept. 12, showed $d_4^{25} 0.9450$, $[\alpha]_D 9.33^\circ$, $n_D^{24} 1.5140$, sapon. no. 8.9, after acetylation 19.4; 1 cc. with 2 drops of 90% alc., gave a turbid mixt.; 1 vol. with 0.4 vol. of 90% alc. a clear mixt.; 1 vol. with 15 vols. of alc. a turbid mixt. With 1 drop of concd. HNO_3 is obtained a bright green color soon changing to reddish brown and, with excess of acid, to bright red. With concd. H_2SO_4 is produced a brownish purple soon changing to rose on the edges; with concd. HCl a dull red color; with glacial $AcOH$ no color; with concd. HCO_2H a

purple color soon changing to reddish brown; with concd. aq. KOH no change; with boiling 0.5 *N* alc. KOH a very dark color. Shaking with excess of 5% KOH produces no change in vol., showing the absence of more than traces of phenols no aldehydes could be detected with Schiff's reagent, NaHSO₃ or NH₄OH; no anethole sepd. in a freezing mixt. after several hrs. The Zeisel method showed 15.9% MeO (that it was not EtO or a mixt. of MeO and EtO was shown by passing the alkyl halide formed into PhNMe₂; PhNMe₂I, m. 212-3°, was obtained). After sapon. the oil yielded fractions with the following b. p., d_{25}^{25} and $[\alpha]_D$, resp.: (1) 165-80°, 0.8440, 68.56°; (2) 180-210°, 0.9830, 48.34°; (3) 210-2°, 0.9640, 0.25°; (4) 212-25°, 0.9680, 0.20°; (5) 225-40°, —, —. (1) gave a nitrosyl chloride, m. 103°, but the m. ps. of the nitropiperidine and -benzylamine made the presence of pinene doubtful; no phellandrene could be identified in (1) and (2) through the nitrosite; that (3) contained methylchavicol was shown by its oxidation by KMnO₄ in dil. AcOH to homoanisic acid, but that it also contained other substances was shown by the fact that an MeO detn. gave only 16.98%, that it showed an ester no. of 9.12 and, after acetylation, of 46.85. No camphor could be detected in (2) or (3) through the oxime. (3) heated 50 hrs. with 0.5 part C₆H₄(CO)₂O, cooled, poured off from the C₆H₄(CO)₂O, dissolved in Et₂O, extd. several times with 5% soda, treated with NaOH and distd., gave a small amt. of a solid sepg. from petr. ether in hexagonal plates m. 203-4°, and giving a phenylurethan m. 138-9°, showing that borneol is a constituent of the oil. Together with the urethan were obtained a few larger crystals, m. 149-50°, indicating the presence of a 2nd alc. in the oil. Fractionation of the oil obtained from cultivated plants gave fractions with the following b. ps., $n_D^{20.5}$ and $[\alpha]_D$, resp.: (1) 170-6°, 1.4735, 62.6°; (2) 176-80°, 1.4769, 71.0°; (3) 180-95°, 1.4880, 57.4°; (4) 195-210°, 1.5118, 15.4°; (5) 210-2°, 1.5210, 0.7°; (6) 212-22°, 1.5221, 0.1°; (7) 222-36°, 1.5260, -0.2°. (1) gave the nitrosyl chloride, m. 103°. (2)-(6) gave a purple color with HCO₂H, the intensity diminishing with rising b. p. and (7) producing no color; with HNO₃ (4) gave a green color. (1) must contain at least 1 terpene, either sabinene or sylvestrene rather than α -pinene. While the physical consts. of (2) indicate the presence of limonene, nothing in the odor suggests it. Acidification with H₂SO₄ of the alk. liquid resulting from sapon., subsequent fractional steam distn., neutralization with NaOH, concn. and treatment with AgNO₃ gave dark Ag salts (possibly owing to the presence of HCO₂H), containing 33.67, 39.8, 69.45 and 73.9% Ag, resp. The residue remaining after the steam distn., when heated with BaCO₃ and H₂O, filtered and treated with AgNO₃, yielded a light yellowish ppt. with 25.22% Ag.

CHAS. A. ROULLER.

Condensation of vanillin and piperonal with certain aromatic amines. ALVIN S. WHEELER. *J. Am. Chem. Soc.* 37, 1362-4 (1915).—W. discusses certain points in which his observations (*C. A.* 7, 3506) are at variance with those of Manchot and Furlong (*C. A.* 4, 459).

CHAS. A. ROULLER.

The color of some cyclic ketonic acids and their esters. HANS STOBBER. Leipzig. *Ber.* 48, 441-6 (1915).—The difference in color between the Bordeaux-red allochryso-ketonic acid (a) and its light yellow Et ester was formerly explained (*C. A.* 1, 2705) as being due to difference in constitution on the basis of Hantzsch's theory (*Ber.* 39, 3080 (1906)). The absorption of (a) and of the similar compds., 9-ketofluorene-4-carboxylic acid (b), phenylindonacetic acid (c) and ketofluorene (d), as well as of the Et esters of (a) and (b) and the Me ester of (c), has since been detd. by the Hartley and Baly method. The absorption of the esters is almost identical with that of the corresponding acids, so that ester and acid are analogously constituted. The compds. (a)-(d) all show selective absorption, at the higher concns., in the region of the long wave lengths. The very flat bands of (b) and (d) cover the region λ 415-345 μ . The band of (c) in 0.01 *N* soln. 10 mm. thick reaches to λ 465 μ , that of 0.01 *N* (a) to λ 526 μ when

6-8 mm. thick and to about λ 555 μ m when 10 mm. thick. Besides these typical bands, (a), (c) and (d) show a pronounced band at about λ 285 μ m, (b) a greatly flattened band. Finally, in the extreme ultraviolet there is again selective absorption. The acids, therefore, show the same 3 typical characteristics as the ketone (d) and are true ketonic acids, and not, as previously assumed for (a), HO lactones. C. A. R.

Molecular compounds of inorganic halides. VI. Action of titanium tetrachloride on organic compounds containing oxygen. ARTHUR ROSENHEIM, with RICHARD SCHNABEL AND ROBERT BILECKI. Berlin. *Ber.* 48, 447-52(1915); cf. Hauser and Levite, *C. A.* 9, 1180.—When 3 mols. *o*-HOC₆H₄CO₂H in abs. Et₂O is boiled with TiCl₄ there are obtained purple-red crystals (a) (cf. *Ber.* 38, 2781(1905)), easily losing HCl in the air and m. 115° (decompn.) when heated rapidly. They have the comp. TiCl(OC₆H₄CO₂H)₃.HCl; the 3 org. acid residues are bound to the Ti by a primary and a secondary valence and form a complex in whose 2nd sphere (using the Werner nomenclature) are the Cl anion, bound by a primary valence, and the added HCl mol.; i. e., the compd. is entirely analogous to those formed by the action of SiCl₄, TiCl₄ and BCl₃ on 1,3-diketones (Dilthey, *Ann.* 344, 300(1906)). With TiBr₄ instead of TiCl₄ is obtained the Br compd. TiBr₃ and 2-3 mols. *o*-HOC₆H₄CO₂Me give the compound [Ti(OC₆H₄CO₂Me)₃]₂TiCl₄, unstable, ruby-red crystals. When (a) is heated in dry air at 65-70°, it loses about 0.5 of its Cl; probably the mol. of HCl is split off; if the temp. is raised to 140-50°, best in CO₂, the total loss in wt. is 39%, and Ti(OC₆H₄CO₂)₃ (Levi, *Ann. chim. phys.* [6] 25, 433) remains; this compd. is more easily obtained from TiCl₄ and 2 mols. HOC₆H₄CO₂H boiled in C₆H₆ at least 6 hrs. Treated with C₆H₅N in abs. alc. it gives a pyridinium salt, OTi(OC₆H₄CO₂C₆H₅N)₃, light yellow microscopic prisms. On the other hand (a) under the same conditions gives a salt in orange-red, microscopic needles of the comp. O.C₆H₄.CO.OTi(OC₆H₄CO₂C₆H₅N)₃, probably identical

with Hauser and Levite's OTi₂(OC₆H₄CO₂H)₄(C₆H₅N)₄. *m*- and *p*-HOC₆H₄CO₂H give with TiCl₄ no characteristic compds. corresponding to (a). Of the cresotinic acids, only those having the OH in the *o*-position to the CO₂H react like *o*-HOC₆H₄CO₂H, 4,2-Me(HO)C₆H₃CO₂H giving the compound Ti(OC₆H₃MeCO₂H)₃.Cl.HCl, purple-red crystals with cantharides luster, which when heated yields the compound Ti(OC₆H₃MeCO₂)₃, brick-red powder sol. in alc. with yellow color, while with C₆H₅N in alc. is obtained the salt O.C₆H₃Me.CO.OTi(OC₆H₃MeCO₂C₆H₅N)₃, red-yellow crystals.

CHAS. A. ROULLIER.

Catalytic reduction of organic halogen compounds. W. BORSCHKE AND G. HEIM-BÜRGER. Univ. Göttingen. *Ber.* 48, 452-8(1915).—The following observations show that under certain conditions organically combined halogen can again be replaced by H in catalytic reductions; what conditions favor this resubstitution and how it proceeds, whether by the dissociation of the halogen compd. into halogen and a free radical and subsequent addition of the H activated by the Pd, or through an organo-metallic compd. RPdX which with H forms a hydrocarbon, HX and Pd, cannot yet be detd. *ω*-Chlorovinyl-3,4-methylenedioxybenzene, CH₂O₂C₆H₃CH:CHCl, obtained in 11 g. yield from 19.2 g. β -piperonylacrylic acid and 6.9 g. K₂CO₃ in 69 cc. H₂O at 0° treated with 200 cc. of 5% KOCl and then with a slow current of CO₂, needles from alc., m. 29-30°; 9.1 g. of this in 40 cc. of 90% alc., treated with 0.05 g. Pd colloid in a few drops of H₂O and shaken with H at 17°, absorbed practically 4 atoms H without any diminution in velocity after 2 atoms had been absorbed, and gave 5.3 g. of CH₂O₂C₆H₃H₂Et. *p*-Methoxy-*ω*-chlorosytrene, obtained in 57% yield from MeOC₆H₄CH:CHCO₂H, leaflets from alc. or Et₂O, m. 34°, smells of anise; with Pd and H in 90% alc. it gives 85% of MeOC₆H₄H₂Et in 1.5 hrs.; in acetone the reduction is complete only after 5 hrs. but the product is the same. From 18 g. PhCH:CHBr shaken with H and Pd until absorption of the H

ceased was obtained 6.4 g. PhEt; when 6.1 g. were shaken until only approx. 2 atoms of H had been absorbed, 1.1 g. PhEt was obtained; the rest of the product boiled higher and contained halogen. To det. whether these reductions proceeded according to the scheme $RCH_2CH_2X \rightarrow RCH:CH_2 \rightarrow REt$, 12.6 g. $PhCH_2Cl$ in an equal part of alc. was shaken with H and Pd; this gave 7 g. PhMe. Under the same conditions, $PhCHCl_2$, after several days, gives some PhMe, an inseparable mixt. of $PhCH_2Cl$ and BzH, and a little $(PhCHCl)_2$. $PhCCl_3$ is slowly but almost completely reduced to $(PhCCl_2)_2$ (12 g. from 19.5 g. $PhCCl_3$). CHAS. A. ROUILLER.

1-Naphthol 5-mercaptan. H. RENNERT. Marburg. Ber. 48, 549-70(1915); cf. Zincke and Ruppertsberg, C. A. 9, 1058.—**Sodium 1-carbethoxynaphthol-5-sulfonate**, needles from H_2O , is obtained when 100 g. com. 1,5- $C_{10}H_6(OH)SO_3Na$ in 1 l. H_2O is shaken with 20 cc. each of $N Pb(OAc)_2$ and $N Na_2S$, filtered and treated with 20 g. NaOH and 40-5 g. $ClCO_2Et$; with PCl_5 it gives 90% of the *sulfonyl chloride*, $EtO_2COC_{10}H_6SO_2Cl$, needles from benzene, m. 79° , easily hydrolyzed back to the acid by alkalis but very stable towards HCl; boiled a short time with $PhNH_2$ in AcOH it gives the *sulfanilide*, leaflets from alc., m. 129° . From 50 g. of the chloride slowly added to 50 g. Zn dust in 200 cc. alc., then gradually treated with 100 cc. concd. HCl and heated a short time on the H_2O bath, is obtained 50-60% of the *mercaptan*, cryst. crusts from alc., m. $41-2^\circ$, very stable in the air but quickly oxidizing in alk. soln.; *acetate*, $EtO_2COC_{10}H_6SAc$, silky needles from dil. alc., m. 86° . With concd. $FeCl_3$ the mercaptan in warm alc. gives the *disulfide*, leaflets from benzene, m. 87° , while with alc., soda and Me_2SO_4 is obtained the *methyl sulfide*, needles from MeOH, m. 79° , which with Cl in AcOH or $CHCl_3$ gives only tarry products; when treated in 5 parts AcOH with a slight excess of Br, however, it yields a *bromo perbromide*, probably 4,1,5- $C_{10}H_6Br(OCO_2Et)SMeBr_2$, red-brown needles, m. 103° (decompn.), quickly changes and is converted by warm H_2O into the *sulfoxide*, $C_{10}H_{11}O_2SBr$, needles from benzene, m. $119-20^\circ$. **1-Carbethoxynaphthol methyl 5-sulfone**, from the sulfide in AcOH and excess of H_2O_2 on the H_2O bath, needles from C_6H_6 -benzene, m. $94-5^\circ$. **Benzyl 5-sulfide**, from the mercaptan, soda and $PhCH_2Cl$ in cold alc., leaflets from alc., m. $136-7^\circ$; with Cl in AcOH it gives the above $EtO_2COC_{10}H_6SO_2Cl$, while in $CHCl_3$ is obtained the compd. (a) below. **Sulfone**, from the sulfide and H_2O_2 in AcOH, needles from alc., m. 130° . **1-Naphthol 5-mercaptan**, from the EtO_2C deriv. boiled a short time with dil. NaOH in the presence of a little Na_2S , needles from C_6H_6 -benzene, m. $131-2^\circ$, quickly oxidizes in alk. soln.; *diacetate*, needles from alc., m. $149-50^\circ$. **Disulfide**, from the EtO_2C deriv. by hydrolysis in alc. soln., needles from AcOH, m. 212° , sol. without change in alkalis; *diacetate*, leaflets from AcOH, m. 154° . **Methyl sulfide**, from the EtO_2C deriv. and alc. alkali, leaflets from dil. alc., needles from C_6H_6 -benzene, m. $154-5^\circ$; Cl in $CHCl_3$ gives brown amorphous products and in AcOH brown tarry substances; *acetate*, needles from alc., m. $77-8^\circ$; *methyl ether*, $MeOC_{10}H_6SMe$, from the $HOC_{10}H_6SH$ or $EtO_2COC_{10}H_6SH$, NaOH and Me_2SO_4 , silvery leaflets from AcOH, m. 134° . **Sulfone**, $HOC_{10}H_6SO_2Me$, from the EtO_2C compd. and alc. NaOH, needles from H_2O , m. 163° . **Benzyl sulfide**, silky needles from C_6H_6 -benzene, m. 130° ; *acetate*, leaflets from AcOH, m. 157° . **Sulfone**, needles from AcOH, m. 234° , nitrated by HNO_3 (d. 1.4) and apparently converted into a keto chloride by Cl in $CHCl_3$; *acetate*, needles from alc., m. 118° . **1-Naphthol-5-sulfonic acid**, obtained in 80% yield from 10 g. of the $EtO_2COC_{10}H_6SO_2Cl$ and 5.5 g. $NaHCO_3$ slowly added to 10 g. crystd. Na_2SO_3 in 50 g. H_2O gradually heated to $50-60^\circ$, crystals from Et_2O -benzene, decomps. above 120° ; with HBr it apparently gives chiefly the disulfide; Me ether, from the Ag salt and MeI, is identical with the above Me sulfone; *dimethyl ether*, obtained with alk. Me_2SO_4 , silky needles from dil. MeOH, m. 98° . Both the $EtO_2COC_{10}H_6SCH_2Ph$ and $EtO_2COC_{10}H_6SH$ with Cl in $CHCl_3$ give a *compound (a)*, probably 2,4,5,6,8,1- $C_{10}H_2Cl_6OCO_2Et$, needles from ben-

zine, m. 129–30°, does not liberate I in AcOH from KI and is not changed by SnCl_2 or PhNH_2 ; alkalis hydrolyze the EtO_2CO group and eliminate Cl, probably with substitution of HO for it; the EtO_2CO group could not be split off with concd. or alc. HCl. The product of the alk. hydrolysis, needles from benzene, m. 172°, has a Cl content (38.17%) corresponding to the formula $\text{C}_{10}\text{H}_7\text{O}_2\text{Cl}$. $\alpha\text{-C}_{10}\text{H}_7\text{OCO}_2\text{Et}$ with Cl in CHCl_3 also yields a compound, $\text{C}_{12}\text{H}_9\text{O}_2\text{Cl}$, leaflets, m. 126–7°, which with alkali loses the EtO_2CO group and Cl; the product in AcOH with HNO_3 and CrO_3 gives a dark yellow quinone yielding an anilide, dark red needles, m. 209°. CHAS. A. ROULLER.

Thioamides. AUGUST ALBERT. Munich. Ber. 48, 470–3(1915).—If the HO group of $\alpha\text{-HO}$ nitriles is protected by acetylation or benzylation, the nitriles add H_2S smoothly to form thioamides, $\text{RCH}(\text{OAc})\text{CSNH}_2$ (R being either aliphatic or aromatic). In the presence of alc. $(\text{NH}_4)_2\text{S}$ the addition takes place in the cold, but if there are present groups sensitive to $(\text{NH}_4)_2\text{S}$, such as NO_2 groups, it is better to use AcSH or AcSNH_2 . $\alpha\text{-Acetoxyisobutyric thioamide}$, obtained in 2.6 g. yield from 4 g. $\text{Me}_2\text{C}(\text{OAc})\text{CN}$ in 12 cc. C_6H_6 and 4 cc. alc. satd. at 0° with NH_3 treated to satn. with H_2S , shaken some hrs. while thoroughly cooled and allowed to stand overnight in a cool place, leaves, m. 123°; there is also formed a faintly yellow oil giving a strong test with Ph_2CCl_2 . $3,4\text{-Methylenedioxyacetylmandelonitrile}$, obtained in 85% yield from 20 g. KCN and 30 g. piperonal in 40 cc. H_2O slowly treated with 30 cc. cold concd. HCl and subsequent heating of the resulting oil in 4 parts Ac_2O and 7 g. NaOAc for 1 hr. on the H_2O bath, prismatic tables from alc., m. 71°; thioamide, prepd. as above in 87% yield, needles from alc., m. 145°. *Acetylmandelic thioamide*, m. 105°. *o-Nitroacetylmandelic thioamide*, from 2 g. of the nitrile in 20 cc. C_6H_6 boiled 2 hrs. with 1.5 cc. AcSH , broad tables from alc., m. 145°; the compd. is better obtained (nearly 100% yield) when 2 g. of the nitrile in 20 cc. C_6H_6 and 3.5 cc. alc. satd. with NH_3 at 0° is treated 3 min. with H_2S , then with 3.5 cc. of AcSH , and allowed to stand in a cool place for 24 hrs. *o-Nitrobenzoylmandelic thioamide*, long, rectangular tables from AcOH, m. 173° (decompn.). CHAS. A. ROULLER.

Indigoid dyes containing sulfur. I. Thioindole derivatives. A synthesis of indirubin. AUGUST ALBERT. Munich. Ber. 48, 474–83(1915); cf. preceding abstr. —When 20 g. $\text{o-O}_2\text{NC}_6\text{H}_4\text{CH}(\text{OBz})\text{CN}$ in 200 cc. cold C_6H_6 and 40 cc. alc. satd. at 0° with NH_3 is treated 1.5–2.0 hrs. with H_2S and kept, tightly closed, overnight in a cool place, quickly filtered, washed with ligroin, dried on clay and freed from S with slightly warm CS_2 , there is obtained 17 g. of *o-hydroxylaminobenzoylmandelic thioamide* (a), seps. from 2 parts alc. + 1 part H_2O in exceedingly fine, long tables with 1 EtOH + 0.5 H_2O , decomp. 159–64°, depending on the manner of heating; it dissolves in 1 mol. warm NaOH and on cooling a colorless Na salt seps.; this on gentle warming with alc. regenerates (a). (a) gently warmed in excess of aq. alkalis becomes red, then intensely blue-violet, the colors persisting for quite a long time in the cold but disappearing on heating higher. Shaken 2 hrs. with dil. HCl, (a) loses NH_3 and forms *N-hydroxy-2-thio-3-benzoyloxindole* (b), $\text{C}_6\text{H}_4\text{CH}(\text{OBz})\text{CS.NOH}$, needles with 1 MeOH , sinters

39°, m. completely 87° to a green liquid, foams 166°, turning violet; free from alc. of crystn., it m. 97–8°; 1 g. treated with 3 cc. H_2O and 2 cc. Ac_2O gives the acetate, 6-sided tables from MeOH or AcOH , m. 106–8° (decompn.). With excess of aq. alkalis, (b) shows the same color reactions as (a); 5 g. in 50 cc. cold H_2O and 40 cc. of N NaOH deposits after 1–2 hrs. 1.5–1.8 g. of fine, hair-like, blue needles, for the most part sol. in cold H_2O with blue color; the insol. part (0.2–0.3 g.) consists of approx. equal amts. of indigo and a dye (probably indirubin) easily sol. in alc. with red color. From the blue aq. soln., solid NaOH or HCl, but CO_2 best, ppts. a cryst. blue-violet dye, quite sol. in ordinary solvents with the same color (high-boiling solvents are not well adapted

to its purification as it decomps. above 140° , sol. in dil. NaOH with blue color and salt formation but decompd. on warming; the vat obtained with hydrosulfite and NaOH dyes wool, cotton less easily, in gray-violet shades; with alk. NH_4OH is obtained an oxime sol. with wine-red color; above 160° , the dye decomps. explosively with evolution of SO_2 and formation of a new compd. insol. in alkalies. The m. p. varies very widely with the manner of heating; when heated slowly it does not m. 200° ; if placed in a bath at 155° , it decomps. 170° , while if the bath is heated to 158° , the dye decomps. 158° . A. believes it is *2-indole-3-N-hydroxythioindolindigo* (c), $\text{NH}_2\text{C}_6\text{H}_4\text{CO}_2\text{C}:\text{C}:\text{CS.N(OH).C}_6\text{H}_4$. He explains the fact that it contains only 1 HO

group, instead of 2 as would be expected from its formation from (b), as being due to the exchange, after the elimination of the Bz group, of the OH on the N for the H on the C opposite: $\text{C}_6\text{H}_4\text{CH(OH).CS.NOH} \rightarrow \text{C}_6\text{H}_4\text{C(OH).CS.NH} \rightarrow$

$\text{C}_6\text{H}_4\text{CO.CS.NH}$ (d); (d) then condenses with 1 mol. hydroxythioindole to form

(c), and also to some extent with itself to form indigo. With BzCl and aq. NaOH, (c) gives 90% of the *N-benzoate*, long, dark blue needles from boiling CS_2 , decomps. $155\text{--}61^{\circ}$, depending on the method of heating, deflagrates with formation of a white sublimate on heating in a test tube, insol. in alkalies. 5 g. (b) warmed 2 hrs. on the H_2O bath with 15 g. Na_2S in 150 cc. H_2O and 100 cc. of satd. NaHCO_3 gives 1.5 g. of indirubin; the mother liquors on oxidation in the air deposit a small amt. of a blue dye insol. in alkalies and containing S.

CHAS. A. ROUVILLER.

An oxidation product of orcinol. F. HENRICH, W. SCHMIDT AND F. ROSSTREUTSCHER. Univ. Erlangen. Ber. 48, 483-9(1915).—When 200 g. orcinol rubbed up with a little H_2O is dissolved in 100 g. KOH in 200 cc. H_2O , filtered, dild. to 3.5 l. and allowed to stand 14 days exposed to the air in a large dish, it gradually becomes more and more brown; it is then acidified, filtered after 1 day and the ppt. dried; it forms a brown-red cryst. mass with 0.04% ash and seps. from dil. alc. or glacial AcOH, when not heated too long, in ruby-red crystals (a), m. $178\text{--}81^{\circ}$ (decompn.), having the comp. $\text{C}_{14}\text{H}_{12}\text{O}_8\cdot\text{H}_2\text{O}$, losing its H_2O after 2-3 hrs. at 145° ; it now decomps. 195° and is easily sol. in cold soda; it can be purified by heating on the H_2O bath in a little H_2O with BaCO_3 for some time, filtering hot, cooling and adding dil. HCl. Distd. with Zn dust in H, it gives a brown oily mass which, when washed in Et_2O with NaOH and H_2O , yields a heavy, brown, non-crystallizable oil. Boiled 0.5 hr. with Ac_2O , it gives a triacetate, $\text{C}_{20}\text{H}_{18}\text{O}_8$, crystals from C_6H_6 -ligroin (1:4), m. 127° , hardly attacked by cold alkalies, dissolving with brown-red color on heating (at once in alc. KOH), sol. in AcOH with yellow color which quickly disappears on boiling with Zn dust. (a) suspended in 20 parts H_2O and satd. with SO_2 , filtered and extd. repeatedly with Et_2O , gives a pentahydroxyditolyl, $(\text{HO})_5\text{C}_6\text{HMeC}_6\text{H}_2\text{Me(OH)}_5$, needles from H_2O containing SO_2 , m. 254° , reduces Fehling and $\text{NH}_4\text{-Cu}$ solns., oxidized back to (a) by $\text{K}_2\text{Cr}_2\text{O}_7$ in dil. H_2SO_4 , slowly in alk. soln. by air and, quickly, by H_2O_2 . Penta-acetate, crystals from C_6H_6 -ligroin (1:1), m. 155° , mol. wt. in freezing CHCl_3 471-97, attacked by alkalies only on warming. (a) is probably a hydrate of a hydroxyquinone, $(\text{HO})_5\text{C}_6\text{H}_2\text{MeC}_6\text{-HMe(OH)(O)}_2$.

CHAS. A. ROUVILLER.

Molecular weights of the monochloroacetic and α,β -dibromopropionic acids showing double melting points. B. TOLLENS. Univ. Göttingen. Ber. 48, 489-96 (1915).—The following are the av. mol. wts. found for the 2 acids: in freezing H_2O , 90, 221; C_6H_6 , 175, 400; $(\text{CH}_2\text{Br})_2$, 209, 375; in boiling Et_2O , 89, 197; acetone, 96, 215; C_6H_6 , 167, 278. In boiling H_2O , $\text{CH}_3\text{CICO}_2\text{H}$, which is not greatly decompd., gave 68.6-82.1; $\text{CH}_2\text{BrCHBrCO}_2\text{H}$, which is decompd. to a large extent, gave 82.1-96.1. In agreement with Tanatar, Tollens finds, therefore, that the stable and labile forms

of the 2 acids have the monomol. formula in H_2O , Et_2O and acetone and that no transformation effected by heat is necessary, since the f. p. measurements in H_2O and the b. p. detns. in Et_2O and acetone were made at temps. below 63° , the transformation temp. of the stable into the labile forms; the crystn. peculiarities apparently have no connection with the mol. magnitudes.

CHAS. A. ROUILLER.

Morphine. MARTIN FREUND, with H. HERMINGHAUS. Univ. Frankfurt. *Ber.* 48, 497-502(1915); cf. *C. A.* 5, 3810.—The amino oxide $C_{17}H_{19}O_4N$ is obtained in 38 g. yield from 40 g. morphine digested on the H_2O bath with 40 cc. of 30% H_2O_2 , stirred up with abs. alc. and filtered, 8-10 g. of the product not sepg. until the filtrate is concd. *in vacuo*, 18 g. slowly added to 90 cc. cold Ac_2O and 9 cc. concd. H_2SO_4 , boiled a short time, gradually treated with 300 cc. alc., warmed till a cryst. deposit begins to form, cooled, filtered and the filtrate repeatedly evapd. and treated with fresh portions of alc. till no deposit is any longer formed, gives 23 g. of the compd. $C_{24}H_{40}O_{11}N_2S_2$ (a), pptd. from NH_3 by dil. H_2SO_4 in needles, gradually blackens about 280° , reduces Fehling soln.; boiled a long time with alkali, acidified and filtered, it gives $BaSO_4$ with $BaCl_2$; in dil. HNO_3 it dissolves with yellowish red color and soon deposits fine, yellow needles, becoming colorless when pressed out on clay and turning deep red and decomp. on the addition of alkali; on a Pt foil they deflagrate. Warmed with aq. SO_2 until dissolved, cooled and evapd., (a) gives the compd. $C_{17}H_{21}O_7NS$, prisms, m. above 300° . From 5 g. (a) heated 5 min. at 110° with 20 cc. H_2SO_4 (d. 1.84), poured hot into 40 cc. H_2O , rubbed to crystn. and treated with 60 cc. more of H_2O , is obtained the *anhydro deriva-*

to the b. p. of H_2SO_4 ; rubbed with dil. HNO_3 , it gives unstable yellow needles becoming colorless on clay; with aq. SO_2 on the H_2O bath it gives a compound, $HO_3SC_{17}H_{18}O_3 : N$, yellowish green needles, decomp. on boiling with H_2O and even on soln. in NH_3 and pptn. with dil. H_2SO_4 ; it is best crystd. from a mixt. of dil. $AcOH$ and SO_2 and blackens 275° .

CHAS. A. ROUILLER.

3,6-Diaminoselenopyrnone (3,6-diaminoxanthoselenonium). P. EHRLICH AND HUGO BAUER. Georg-Speyer-Haus, Frankfurt a/M. *Ber.* 48, 502-7(1915); cf. *C. A.* 8, 2885.—From 10 g. $(p-H_2NC_6H_4)_2CH_2$ in 500 cc. concd. H_2SO_4 nitrated below 0° with 42 cc. of 100% HNO_3 and 150 cc. concd. H_2SO_4 and subsequently diluted with 6-7 l. H_2O is obtained 158 g. of the *o,o'*-dinitro compd. as sulfate, from which NH_3 liberates the base in a pure state; the H_2SO_4 mother liquors yield 33.5 g. more of less pure base. From 58 g. of this in 290 cc. hot $AcOH$ and 15 g. $NaOAc$ gradually treated with 47 cc. Ac_2O is obtained quant. the di-Ac deriv., 74.5 g. of which, suspended in 1200 cc. alc., treated with 300 g. $SnCl_2$ and 300 cc. HCl (d. 1.19) at 40° , kept several hrs. in the ice chest, filtered, washed with alc., suspended in 1 l. H_2O , decompd. with H_2S , repeatedly extd. with boiling H_2O and pptd. with NH_3 , gives on an av. 40 g. of $[2,4-H_2N(AcNH)-C_6H_4]_2CH_2$; when 15.6 g. of this, suspended in 120 cc. H_2O , are treated with 37 cc. of HCl (d. 1.12), then with ice and 20 cc. of 5 N $NaNO_2$, stirred until the red bisdiazotized compd. has sepd., treated with $NaOAc$ soln. until the reaction to Congo disappears and mixed with 15 g. $KCNSe$ in a little H_2O , stirred for 1 hr. and allowed to stand several hrs., there is obtained 18 g. of a product which is boiled with alc. until nothing more dissolves; there remains a small amt. of a dark brown residue. The 1st alc. ext. on evapn. leaves a dark evil-smelling tar; the subsequent exts. on concn. deposited

amorphous, yellow to brown, sandy ppts. of varying comp., containing considerably less Se than calcd. for the expected intermediate product, $[\text{NCSe}(\text{AcNH})\text{C}_6\text{H}_5]_2\text{CH}_2$; 5 g. of this, heated 1 hr. on the H_2O bath with 25 cc. of concd. H_2SO_4 , then treated with 250 cc. H_2O , filtered, warmed a short time with HCl (d. 1.12), filtered and dild. with

H_2O , gave 2.1 g. of 3,6-diaminoselenopyrnone chloride (a), $\text{CH} \begin{array}{c} \diagup \text{C}_6\text{H}_4(\text{NH}_2) \diagdown \\ \diagdown \text{C}_6\text{H}_4(\text{NH}_2) \diagup \end{array} \text{SeCl}$,

needles with green metallic luster from alc., quite difficultly sol. in H_2O and alc. with red color and no fluorescence, in concd. H_2SO_4 with blood-red color persisting on addition of a little H_2O while more H_2O ppts. out most of the dye. NaNO_2 in HCl gives an almost colorless diazo compd. coupling red with resorcinol or R salt. NaOH ppts. the base in blue-red flocks sol. in Et_2O without color as the carbinol compd. and reforming the dye when shaken with acids, including AcOH ; $(\text{NH}_4)_2\text{CO}_3$ ppts. red flocks of the carbonate, sol. on warming with red color. As compared with the S compd. (b), (a) dyes silk with a much more bluish tinge (somewhat like "Cerise") and tannated cotton a bluish red similar to safranin; the cotton dye is fast to washing but neither the cotton nor silk dye is fast to light. In trypanosomiasis, (a) and (b) produce only transitory healing effects. The toxic dose for a 20 g. mouse is about 1/2500 g. of (b) and 1/3000 g. of (a). Both dyes produce pronounced edema in mice. C. A. R.

Resorcinolarsonic acid and some of its derivatives and reduction products. HUGO BAUER. *Ber.* 48, 509-24(1915); cf. *Farb. v. M. L. & B., C. A.* 8, 2459.—*Resorcinolarsonic acid* (2,4-dihydroxyphenylarsonic acid), obtained in 145 g. yield from 110 g. $m\text{-C}_6\text{H}_4(\text{OH})_2$ heated on the H_2O bath with 171 g. com. H_2AsO_4 (75° Bé.) for 2 days, rubbed up with AcOH and washed repeatedly with AcOH , crystals from the aq. soln. containing AcOH slowly evapd. in a desiccator, m. 191°, gives a dark red color with FeCl_3 , does not reduce $\text{NH}_3\text{-AgNO}_3$ even on heating; the crystals are triclinic pinacoidal, $a:b:c = 0.8088:1:0.4349$, α 84° 21' 15", β 104° 40' 30", γ 79° 31' 30", prisms (a) 100, b (010), m (110) with the end surfaces g (011), c (001), with perfect cleavage along b (010). From 46.8 g. of the acid in 50 cc. concd. H_2SO_4 treated below 0° with 14 cc. each of HNO_3 (d. 1.4) and concd. H_2SO_4 and allowed to stand overnight, is obtained 41.7 g. of the 5-nitro acid, faintly yellow needles with 2 H_2O , which it loses at 110°, becoming colorless and then m. 223° (decompn.), gives a red color with FeCl_3 . If 30 cc. each of HNO_3 and H_2SO_4 are used for the nitration at 20° and the temp. is slowly raised to and kept several hrs. at 60°, there is obtained 50 g. of the 3,5-dinitro acid, yellow crystals from H_2O , rubbing to an almost white powder, m. 206° (decompn.), gives a dark orange color with FeCl_3 . With 4 mols. Br in AcOH , the mono- NO_2 acid gives 3,5,2,4- $\text{Br}_2(\text{HO})_2\text{C}_6\text{HNO}_2$, while the di- NO_2 acid with 2 mols. Br in alc., subsequently dild. with an equal vol. of H_2O , freed of the slight excess of Br with bisulfite and of the alc. by warming on the H_2O bath, yields 2,4-dinitro-6-bromoresorcinol, 2,4,3,5- $(\text{HO})_2(\text{O}_2\text{N})_2\text{C}_6\text{HBr}$, yellow prisms from AcOH , m. 89-90°. 2,4-Dihydroxy-5-aminophenylarsonic acid, obtained quant. from 32.5 g. of the NO_2 acid in 300 cc. H_2O and 100 cc. of 10 N NaOH treated with 70 g. $\text{Na}_2\text{S}_2\text{O}_4$, filtered, cooled and neutralized with 62 cc. AcOH , pptd. by NaOAc from dil. HCl in needles with 1 H_2O , darkens 150°, decomps. at higher temps., quickly turned blue in alk. soln. by the air with formation of an indophenol dye, reduces cold $\text{NH}_3\text{-AgNO}_3$, gives with nitrites a yellow diazo soln. coupling blue-red with $m\text{-C}_6\text{H}_4(\text{OH})_2$; in NaOH with Ac_2O it gives an acetyl derivative, quite sol. in H_2O , easily in concd. HCl . 2,4,2',4'-Tetrahydroxy-5,5'-diaminoarsenobenzene (best prepd. from the NH_2 acid, as described below for the di- Ac deriv.), is obtained as the hydrochloride, dark yellow substance, easily sol. in H_2O , by gently warming 6.5 g. of the NO_2 acid in 20 cc. alc. and 25 cc. HCl (d. 1.19) with 25 g. SnCl_2 , adding 20 cc. AcOH , filtering and adding dropwise to 30 cc. ice-cold HCl (d. 1.19), 20 cc.

AcOH and 1 cc. HI (d. 1.7), adding 40 cc. more AcOH and filtering in a CO_2 atm.; NaOH at first ppts. the free base and, when in excess, redissolves it, the alk. soln. being quickly turned blue by the air. *Diacetyl derivative*, from 3 g. of the NHAc acid dissolved in 30 cc. H_3PO_2 (d. 1.136), filtered, treated with 1 cc. HI (d. 1.7) and stirred, yellow powder, easily sol. in NaOH. *2,4,2',4'-Tetrahydroxy-3,5,3',5'-tetraaminoarsenobenzene*, obtained as the *tetrahydrochloride* in 9.1 g. yield from 13 g. of the di- NO_2 acid in 35 cc. H_2O and 80 cc. HCl (d. 1.19) treated at $35-40^\circ$ with 80 g. SnCl_2 , then with 2 g. KI in a little H_2O and poured into 500 cc. of ice-cold HCl (d. 1.19), dull yellow powder, sol. in H_2O with dark yellow, in dil. HCl with light yellow color; NaOH, soda and NaHCO_3 ppt. the free base and, in excess, redissolve it with brown color; the alk. soln. turns blue in the air; in HCl with nitrites is formed a dark ppt., then a light yellow diazo soln. coupling dark red with $m\text{-C}_6\text{H}_4(\text{OH})_2$; in AcOH is formed a dark green ppt. at once turning deep brown, which does not give the diazo compd. on further treatment with HNO_3 and dissolves in NaOH; it is probably a dye of the Bismarck brown type; the same splitting off of the AsO_2H_2 residue and formation of a brown-red dye is effected in soda soln. with diazo-*p*-nitroaniline. *Acetyl derivative*, from the HCl salt in dil. HCl and excess of Ac_2O shaken vigorously with NaOH, brown horny mass, easily powdered, sol. in soda and NaHCO_3 . The HCl salt boiled a few min. in H_2O gives $1,3,2,4\text{-C}_6\text{H}_2(\text{OH})_2(\text{NH}_2)_2\cdot 2\text{HCl}$ which, with nitrites in HCl, gives a dark yellow diazo soln. coupling blue-red with $m\text{-C}_6\text{H}_4(\text{OH})_2$; in AcOH is obtained a dark green ppt. at once changing to a dark brown dye sol. in alkalies, while in soda with diazo-*p*-nitroaniline is formed a brown-red dye; the 2 dyes are probably identical with those obtained from the As:As compd. *2-Methoxy-4-hydroxyphenylarsonic acid*, obtained in 63 g. yield from 100 g. $\text{MeOC}_6\text{H}_4\text{OH}$ and 160 g. H_2AsO_4 (75° Bé.) after 50 hrs. on the H_2O bath, m. 209° , reduced by H_3PO_2 and KI to *2,2'-dimethoxy-4,4'-dihydroxyarsenobenzene*, yellow powder, sol. in NaOH, insol. in soda. From 15 g. of the acid with 30 cc. each of AcOH and HNO_3 (d. 1.4) after 2 days is obtained 8 g. of the *5-nitro-acid*, light yellow scales from H_2O , m. 237° ; 15.5 g. in 150 cc. H_2O and 50 cc. of 10 *N* NaOH with 35 g. $\text{Na}_2\text{S}_2\text{O}_4$ gives 14 g. of the *5-amino acid*, pptd. from dil. HCl by NaOAc in needles with 2 H_2O , darkens about 120° , decomp. at higher temps., gives a yellowish diazo soln. coupling red with $m\text{-C}_6\text{H}_4(\text{OH})_2$ and with $\text{NH}_2\text{-AgNO}_3$ in the cold forms a red-brown soln. depositing Ag on warming. *2,2'-Dimethoxy-4,4'-dihydroxy-5,5'-diaminoarsenobenzene*, obtained as the *hypophosphite*, friable yellow powder, from the NH_2 acid, H_3PO_2 and KI and addition of the resulting soln. to acetone; free base, resinous yellow ppt., sol. in excess of alkali, the soln. turning red when poured upon paper. If the reduction mixt. is poured into concd. HCl instead of acetone, the *hydrochloride* is formed; this, boiled a few min. in H_2O , gives an *aminoresorcinol methyl ether hydrochloride*, needles, decomp. about 220° , which by exclusion must be the $2,4\text{-(HO(MeO))C}_6\text{H}_2\text{NH}_2\cdot\text{HCl}$; NaOH or soda produces a yellow color, quickly followed by the deposition of red flocks (probably an oxidation product), insol. in excess of alkalies and in Et_2O ; FeCl_3 gives a red color; the diazo soln. is yellow and couples intensely red with $m\text{-C}_6\text{H}_4(\text{OH})_2$; $\text{NH}_2\text{-AgNO}_3$ is immediately reduced. *2,4-Dimethoxyphenylarsonic acid*, obtained in 23.3 g. yield from 28 g. $m\text{-C}_6\text{H}_4(\text{OMe})_2$ and 50 g. H_2AsO_4 after 8 days on the H_2O bath, silky needles from H_2O , m. $242-3^\circ$; what is apparently an impure form of the same product is obtained in small amt. from $2,4\text{-(HO)}_2\text{C}_6\text{H}_2\text{-AsO}_2\text{H}_2$ heated 1 day on the H_2O bath with a large excess of alk. Me_2SO_4 . The above compds. show considerable toxicity without, however, a corresponding curative action.

CHAS. A. ROULLER.

The problem of the valence of sulfur. H. LECHER. Acad. Sci. Munich. *Ber.* 48, 524-36(1915).—Aromatic disulfides being the analogs of hexa-arylethanes which are characterized by their power to dissociate into free radicals, owing to the weakening of the 4th valence of the C_6H_5 C atoms by the proximity of the aryl groups, it became

of interest to det. whether the 2nd S valence in the sulfides is similarly weakened. The colorless Ph_2S_2 (a) dissolves in all indifferent solvents with faintly yellow color; the fused (a), m. $60-2^\circ$, is also yellow and can easily be undercooled to room temp. without disappearance of the color, the colorless form crystg. from the melt. On warming, the solns. or melt become more deeply yellow and resume their original color on cooling. That this is not due to a dissociation equil., $(a) \rightleftharpoons 2\text{PhS}$, is indicated by the fact that Beer's law holds in C_6H_6 at room temp. and in xylene near the b. p. (cf. Piccard, *C. A.* 5, 3444). $(p\text{-Me}_2\text{NC}_6\text{H}_4\text{S})_2$ (b), which is yellow even in the solid state, behaves just like (a) in solns. and when fused, and the solid, also, becomes darker when heated to about 100° , resuming its original color on cooling and becoming still lighter at -50° . L. believes that parallel with the gradual increase of color on heating there is a gradual shifting of the valence distribution, the S-S union gradually becoming weaker, so that the compounds should break down at this point when heated. As a matter of fact, (a) is not attacked by Na powder in Et_2O after 2 days' shaking; 2 g. (a) shaken 10 days in ligroin with an alloy of 0.35 g. Na and 1.6 g. K gave 1.7 g. unchanged (a) and a little K_2S and PhSK ; with Na in boiling ligroin (about 80°) in a N atm. there was no action in 1 hr.; while in boiling xylene with the calcd. amt. of Na after 1.5 hrs. the (a) was almost completely converted into PhSNa , the film of the latter depositing on the Na probably preventing complete interaction. Similarly, (b) boiled 2 hrs. with 5 times the calcd. amt. of Na in xylene gives $\text{Me}_2\text{NC}_6\text{H}_4\text{SH}$ almost quant.; of 3 g. (b) boiled 5 hrs. in xylene with an alloy of 40.3 g. Hg and 10 g. Pb, about 0.5 g. is converted into the mercaptan; with Hg alone, there is no reaction. Neither (a) nor (b) reacts with O in boiling xylene. From 6.6 g. (b) and 12.2 g. $\text{C}_2\text{Ph}_3\text{Et}_2\text{O}$ boiled 3 hrs. in PhMe under CO_2 are obtained 2.6 g. unchanged (b) and 9.9 g. 4-dimethylaminophenyl triphenylmethyl sulfide (c), while 20 min. boiling of 10.6 g. (b) with a filtered soln. of Ph_3C prepd. by shaking 19.9 g. Ph_3CCl in 130 cc. xylene with 50 g. Hg for 22 hrs. gave 4.6 g. unchanged (b) and 15.6 g. (c). (c) seps. from alc. in leaflets, sinters about 145° , m. $146-8^\circ$, perfectly stable in the solid state, insol. in dil. HCl or HNO_3 ; HCl in Et_2O ppts. from org. solvents the cryst. *hydrochloride*, insol. in dil. HCl ; boiling AcOH decomps. (c) with yellow color; boiling PhMe produces no color, boiling xylene a faint yellow color which does not disappear on cooling; the soln. does not show the spectrum of Ph_3C , while the dark yellow soln. in boiling C_{10}H_8 does show the Ph_3C spectrum which, however, disappears on shaking but reappears on heating again; the process cannot be repeated often as dark decompn. products make their appearance. In concd. H_2SO_4 (c) dissolves with red color and evolution of SO_2 and after several hrs. ice ppts. Ph_3COH ; after removal of this with Et_2O , addition of NaOH and extn. with Et_2O , (b) is obtained. PhSCPh_3 prepd. by shaking PhSNa with Ph_3CCl in Et_2O for 18 hrs. is identical with the product obtained from PhSH and Ph_3CCl in C_6H_6 (v. Meyer, *C. A.* 5, 1595); it m. $105-6^\circ$, is not decompd. by boiling AcOH , gives no yellow color in boiling xylene, sol. in concd. H_2SO_4 with red color disappearing on addition of H_2O , becomes yellow in boiling BzOEt or C_{10}H_8 with appearance of the spectrum of Ph_3C which disappears on shaking with air and reappears on warming.

CHAS. A. ROUILLER.

Anthranil. XX. Anthranil and methylantranil. EUG. BAMBERGER. Zurich. *Ber.* 48, 537-82(1915); cf. *C. A.* 4, 2281; 5, 3269.—The present work further confirms the homology of anthranil (a) and the Me deriv. *Iz*-methylbenz- β,γ -isoxazole (b)

and thus gives additional evidence of the correctness of the formula $\text{C}_6\text{H}_7\text{N}_2\text{O}$

react in the same way towards HNO_3 , but while the product from (a), $o\text{-OHCC}_6\text{H}_4\text{N}(\text{NO})\text{OH}$, was isolated in cryst. form, that from (b), $o\text{-AcC}_6\text{H}_4\text{N}(\text{NO})\text{OH}$, could be identified only by the color reactions of its solns., apparently because the mixt. of NaNO_2 and HCl used partly converted (b) into the *N*-dichloride (together with much of the diazonium salt, $\text{AcC}_6\text{H}_4\text{N}_2\text{Cl}$). In the hope of avoiding this, H_2SO_4 was substituted for HCl but without the desired result, probably because the product sought is too quickly reduced to the diazonium salt. The product obtained is *o*-acetophenyl-nitroamine (c), $\text{AcC}_6\text{H}_4\text{NHNNO}_2$. After many trials under various conditions, the following was found to be the best method for obtaining it: 2 g. (b) turbinéd 3–4 min. with 40 g. of 14.4% H_2SO_4 is treated in the course of 40 min. at 20 sec. intervals ($1\frac{1}{3}$ cc. drops) with 1.33 g. NaNO_2 in 2.3 cc. H_2O , the ice-cold soln. being continuously stirred and a rapid current of air being drawn over its surface by means of a pump; the turbinéd is continued about 5 min. longer, the NaNO_2 burette rinsed twice with 0.5–1.0 cc. H_2O and the crystals of pure (c) washed with ice H_2O and a little cold Et_2O ; instead of filtering, the soln., kept at 0° and turbinéd until no more free HNO_2 can be detected with starch-KI, may be satd. with $(\text{NH}_4)_2\text{SO}_4$, extd. 3 times with 40 cc. of cold Et_2O , the ext. washed with 0.5 cc. portions of ice H_2O until free from diazonium salt (i. e., until the washings no longer couple with α -naphtholate); after 5 portions of (b) have thus quickly been worked up, the Et_2O and aq. layers are combined, the latter again extd. 4 times with 10 cc. portions of Et_2O ; the H_2O soln. (d) is set away in the ice chest; the Et_2O soln. is extd. 4 times with 25 cc. portions of NH_3 (d. 0.914) (for the Et_2O soln. (e), see below); the NH_3 soln. is extd. 3 times with 3–4 cc. portions of Et_2O (which are combined with (e)), and concd. to 0.2 its vol., the solid on the edges dissolved with a few drops of NH_3 and the cold filtered soln. treated dropwise with 2 *N* H_2SO_4 (only a few drops being added beyond the point where the ppt. no longer completely redissolves); the faintly straw-yellow crystals of (c) (0.15 g.) are washed with ice H_2O until free from H_2SO_4 ; the main portion of (c) (2.35 g.) is pptd. from the filtrate in the same manner; the mother liquors satd. with NaCl and extd. with Et_2O yield a further small amt. The Et_2O soln. (e) above again extd. with 50 cc. NH_3 and fractionally pptd. with H_2SO_4 , as above gives 0.02 and 0.07 g. more of (c) and the filtrates yield 0.04 g. more to Et_2O . The Et_2O soln. remaining after the extn. with NH_3 is freed with NaOH from small amts. of faintly acid substances (pptd. by acids (0.02 g.) in $\text{Fe}(\text{OH})_3$ -like flocks), and after washing with H_2O and a little AcOH and drying with Na_2SO_4 leaves 2.95 g. of a dark red-brown oil yielding on steam distn. 1.98 g. of (b) containing a little AcPh . The H_2O soln. (d) above, slowly poured into 8.3 g. β -naphthol and 34 g. NaOH in 400 g. cold H_2O , gives 8.2 g. of $\text{AcC}_6\text{H}_4\text{N}_2\text{C}_{10}\text{H}_7\text{OH}$, m. $198.5\text{--}9.0^\circ$ (*Ber.* 36, 1621 (1903)); the filtrate from this is satd. with NaOH and extd. 5 times with 40 cc. portions of Et_2O , the Et_2O removed, the residue (0.3 g.) taken up in 2 *N* H_2SO_4 , filtered, made alk. and distd.; the distillate on evapn. in the air deposits a base in needles losing their luster in a few days in the air, easily sol. in dil. H_2SO_4 . AcPh was also often isolated from the H_2O soln. (d). In a prepn. of (c) in which 2 g. (b) in 40 g. of 31.2% H_2SO_4 at -3° was treated in 5 min. with 1.5 g. NaNO_2 in 3 g. H_2O , the Et_2O soln., freed from diazonium salts and acids as above and dried with Na_2SO_4 , deposited in 24 hrs. flat, dark brown-red needles, sol. in concd. H_2SO_4 with brown-red color and m. about 240° after crystn. from AcOH ; concn. of the Et_2O filtrate from these needles yielded 0.12 g. of chocolate-brown crystals sepg. from AcOH in brick-red needles, sol. in fuming H_2SO_4 with brown-red color, m. $217\text{--}8^\circ$. Possibly 1 of these products is *o*-azoacetophenone. Under certain conditions, (b), NaNO_2 and H_2SO_4 also yield a small amt. of a cryst. light red acid, sol. in NaOH and NH_3 with a dark blue color soon changing through gray-blue and violet-blue, violet-red to violet and pptd. unchanged in light red flocks from the fresh soln. by acids. (c) seps. from H_2O in silky needles or prisms (if it is attempted to recrystallize large amts. from H_2O , it partly resinifies), softens 102° ,

m. $103-4^{\circ}$, acid to litmus, Me orange and Congo but not to tropeolin, easily sol. in alkalis, NH_3 and soda, stable when protected from the light, difficultly volatile with only partial decompn. with steam, gives only a faintly brownish color with boiling NH_3 - AgNO_3 containing a little NaOH , does not react after 20 hrs. with $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ in AcOH but with a little Zn gives an intense red-violet color in a few sec.; warmed with dil. H_2SO_4 it becomes yellow and when poured into α -naphtholate the soln. becomes intensely red; if the H_2SO_4 soln. is boiled, it smells intensely of $o\text{-HOC}_6\text{H}_4\text{Ac}$; the same phenomena are obtained with NaNO_2 and H_2SO_4 , AcOH or HPO_3 or with AcOH and Zn dust. *Silver salt*, from a neutral soln. of (c) in NH_3 and AgNO_3 , voluminous ppt., deflagrates violently on a Pt foil, melts and blackens when cautiously heated on porcelain, seps. from boiling H_2O in needles. *Copper salt*, light brown-yellow silky needles. *Lead salt*, silky needles. *Barium salt*. *Phenylhydrazone*, bronze to deep golden yellow, sometimes light tombac-brown leaflets or flat tables from alc., m. 132.5° , sol. without color in NaOH , NH_3 and soda and repptd. by acids in S-yellow cryst. flocks, sol. in concd. H_2SO_4 with deep indigo-blue, in fuming HCl with blue-green color at once changing to deep blue, then in a few min. to dirty green-brown and soon to brown-red; diln. of the brown-red soln. produces no ppt. *p-Nitrophenylhydrazone*, brownish yellow or dark golden yellow needles with violet surface luster from a very slowly evapd. alc. soln., m. 173° (foaming), sol. in 2 N NaOH and 12% NH_3 with dark blood-red color; cold soda dissolves it only slightly with orange color, completely, with deep red color, on heating or addition of NH_3 or NaOH ; on cooling, a *sodium salt* seps. in light brownish Cu-red flat needles with bronze luster, sol. in H_2O and repptd. by 2 N soda; its light yellow aq. soln. is turned deep red by NaOH . The light red is probably a mono-, the deep red a di-Na salt. Conc'd. H_2SO_4 dissolves the hydrazone with yellow to brown color. When 0.5 g. (c) is introduced in the course of 25 min. into 20 cc. of 62% H_2SO_4 at -15° to -10° with const. stirring, the solid particles mashed with a rubber-tipped rod during the next 35 min., the temp. brought down from -3° to -12° in the next hr., the mashing of the solid particles being continued until the soln. is clear, and the latter is poured upon 120 g. of ice and H_2O , dark yellow cryst. flocks are deposited which, when washed with H_2O until free from diazonium salts, then with dil. NH_4 , NaOH and finally H_2O , and steam distd., yield a yellow distillate; this, when allowed to evap. spontaneously and exhausted with Et_2O , gives 3-nitro-2-aminoacetophenone (f), golden yellow needles from alc., m. $92.5-3.0^{\circ}$, easily sol. in concd. H_2SO_4 or HCl with yellow color and repptd. in great part by H_2O ; the yellow acid solns. are decolorized by 1% NaNO_2 with formation of diazonium salts coupling violet-red with α -naphtholate; aq. solns. dye silk in a neutral bath a light yellow color discharged by boiling H_2O containing AcOH ; when boiled with Zn dust and H_2SO_4 , filtered and treated with FeCl_3 , the soln. soon becomes dark orange-red to blood-red and, if sufficiently conc'd., the oxidation product seps. after a time in dark red-brown flocks; heating of the soln. produces a faint quinone odor. The aq. filtrate from the original deposit of (f) is repeatedly extd. with Et_2O , the ext. washed with ice H_2O , NH_3 and dil. NaOH , the Et_2O evapd. and the residue distd. with steam; the non-volatile portion is filtered hot and on concn. deposits a few mg. of 5-nitro-2-aminoacetophenone (g), silky, straw-yellow needles from H_2O , begins to sinter 146° , m. $150-1^{\circ}$, sol. in H_2O with golden yellow color, pptd. to a large extent by H_2O from concd. H_2SO_4 or HCl in light yellow cryst. flocks which dissolve in 1% NaNO_2 without color, the resulting soln. coupling intensely blue with α -naphtholate; boiled to decolorization with Zn dust and H_2SO_4 , the cooled soln., which doubtless contains $2,5\text{-(H}_2\text{N)}_2\text{C}_6\text{H}_3\text{Ac}$, gives with very dil. FeCl_3 a deep blue color turning to green on warming and evolving the odor of quinone. The NH_3 washings of the above Et_2O exts. give traces of a dark brown powder insol. in NH_3 and alkalis, and a little of an acid sol. in NH_3 with brown-red color and repptd. by acids in amorphous flocks. A few mg. of an amorphous brown acid are also obtained from the NaOH wash-

ings. The aq. filtrate from the original deposit of (f), when made alk. with NaOH and extd. with Et_2O , gives a little $o\text{-H}_2\text{NC}_6\text{H}_4\text{Ac}$. Semicarbazone of (f), golden yellow prisms or needles from AcOH, m. 223° , beginning to redden 100° and turning scarlet $115\text{--}20^\circ$; from alc. it seps. in dark orange-red needles on slow cooling, as a scarlet cryst. powder on rapid cooling, from H_2O in silky, orange-red needles or wartlets, often mixed with yellow needles; the yellow also changes into the red form in contact with H_2O or dil. alc., NaOH, soda and NH_3 , the red into the yellow form on moistening with AcOH or HCO_2H ; dil. H_2SO_4 does not change the color of the red form but on warming it dissolves with regeneration of (f). Concd. H_2SO_4 dissolves the semicarbazone without color, H_2O pptg. yellow cryst. flocks or light red needles. When 0.08 g. of (c) in 10 cc. AcOH and 240 cc. H_2O at 0° is treated dropwise with very dil. CaOCl_2 until there is a distinct odor of Cl, light lemon-yellow voluminous cryst. flocks suddenly sep.; these are washed with ice H_2O , then with *N* soda till the washings are alk. to litmus, and again with H_2O ; the resulting golden yellow crystals do not smell of CaOCl_2 , are turned blue in a few sec. by neutral KI-starch; when treated with dil. HCl, especially on warming, they evolve vapors which likewise turn KI-starch paper blue; an aq. suspension boiled 1–1.5 min. yields a clear soln. which no longer reacts with KI-starch when cooled; the alc. soln. with concd. aq. $p\text{-C}_6\text{H}_4(\text{NH}_2.\text{HCl})$, gives a green color in 10–20 sec., then turning to olive-green and finally reddish brown in a few min.; alc. PhNMe_2 produces no color. The crystals are *acetophenylchloronitroamine* $\text{AcC}_6\text{H}_4\text{NCINO}_2$. The aq. soln. boiled until it no longer reacts with KI-starch, then steam distd. and the distillate extd. with Et_2O , yields 4(?)*-chloro-6-aceto-2-nitroaniline*, light orange-yellow, silky, felted needles from alc., m. $142\text{--}3^\circ$, forming yellow solns., pptd. by H_2O from concd. HCl in cryst. flocks, yields a colorless diazonium soln. coupling bluish red with α -naphtholate; reduced with Zn dust and boiling dil. HCl and then treated with FeCl_3 , it deposits dark red-brown flocks. The residue from the steam distn. on cooling deposits a very small amt. of crystals sepg. from H_2O in faintly yellowish silky needles, probably *6-aceto-2(?) -chloro-4-nitroaniline*, whose diazonium soln. couples blue with α -naphtholate; reduction with Zn dust and dil. H_2SO_4 and subsequent treatment with FeCl_3 produces a blue color, changing on heating to green and then dirty brown-red with evolution of a quinone odor. Among the numerous by-products accompanying $o\text{-OHCC}_6\text{H}_4\text{N}(\text{NO})\text{OH}$ (h) in the reaction between (a), NaNO_2 and 23% HCl, the acid which gradually seps. from the wash waters of (h) has been shown to be identical with the acid "M" which accompanies the $o\text{-OHCC}_6\text{H}_4\text{NO}$ formed in the decompn. of the crude (g), and is *o-aldehydophenylnitroamine* (i); it seps. in silky needles, m. $69\text{--}70^\circ$ (total yield of crude product, 0.3 g. from 3 g. (a)), sol. in NaOH, NH_3 and soda; its aq. soln. is acid to litmus, neither colors FeCl_3 nor reduces Fehling soln., forms a white *silver salt* in neutral soln., is volatile with only partial decompn. with steam, forms a yellow *p-nitrophenylhydrazone* sol. in alkalies with intense bluish red color and repptd. by acids in yellow cryst. flocks, only partially sol. in 2 *N* soda with orange-red color changing to dark red on heating; on cooling, golden yellow microscopic needles sep.; concd. H_2SO_4 dissolves the hydrazone with deep red color. *Phenylhydrazone*, S-yellow cryst. flocks sol. in H_2SO_4 with indigo-blue color, changing to yellow with deposition of brown flocks on addition of H_2O ; alkalies dissolve the hydrazone without color, acids repptg. it. Boiled 15–20 sec. with AgNO_3 , NH_3 and a few drops of NaOH, (i) produces a black color; with a little Zn dust in AcOH containing $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ is soon formed a deep violet; with HPO_3 or AcOH and NaNO_2 is obtained a soln. which on short warming produces with α -naphtholate the color characteristic of diazotized $o\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$; on distn. of the soln. is obtained $o\text{-HOC}_6\text{H}_4\text{CHO}$; Zn dust and AcOH effect the same reduction. Boiling with 2 *N* H_2SO_4 rearranges (i) into *aldehydo-o-nitroaniline*, $6,2\text{-OHC}(\text{O}_2\text{N})\text{C}_6\text{H}_4\text{NH}_2$, golden yellow needles, volatile with steam, whose diazonium soln. couples intensely violet (quickly becoming red-brown) with

α -naphtholate, and into the *p*-nitro compound, non-volatile with steam, whose diazonium soln. couples dark blue (changing to yellow-brown) with α -naphtholate. With CaOCl_2 in AcOH (g) gives the *chloroimide*, entirely analogous in its properties to the compd. from (c). Another by-product in the action of NaNO_2 and 23% HCl on (a) is obtained when the alc. filtrate of the crude K salt of (h) is pptd. with Et_2O , filtered and the mother liquors are concd. *in vacuo*. The reddish brown residue, washed with alc. and rubbed with dil. NaOH , gives an acid pptd. in amorphous dirty brown flocks while the part insol. in NaOH (0.28 g. from 16.3 g. (a)) seps. from H_2O in silky, felted needles, insol. in acids or alkalis, m. $108-9^\circ$; *p*-nitrophenylhydrazone, light orange to golden yellow, sol. in alc. NaOH with deep violet-red color. The action of HNO_2 on anthranils may be explained as consisting in the opening of the isoxazole ring with formation of the group $\text{OXCC}_6\text{H}_4\text{N} < (\text{X} = \text{H}, \text{Me})$ which then adds HNO_2 in 2 ways, to form $\text{OXCC}_6\text{H}_4\text{N}(\text{NO})\text{OH}$ and $\text{OXCC}_6\text{H}_4\text{NHNHO}_2$. CHAS. A. ROULLER.

Synthesis of hydroxythiophene derivatives from aminocrotonic ester. ERICH BENARY AND A. BARAVIAN. Univ. Berlin. *Ber.* 48, 593-604 (1915); cf. *C. A.* 4, 312.—When 100 g. $\text{NH}_2\text{CMe}:\text{C}(\text{COCH}_2\text{Cl})\text{CO}_2\text{Et}$ in 350 cc. alc. is treated with 300 cc. of 33% KSH , the resulting mercaptan at once loses NH_3 and condenses to *ethyl 5-thiololene-3-hydroxy-4-carboxylate* (I), needles from alc., m. $64.5-6.0^\circ$ (yield, 75 g.), gives a dark blue color with alc. FeCl_3 , sol. in concd. H_2SO_4 with intense yellow-green fluorescence, tastes bitter. The *methyl ester*, leaflets from MeOH , m. $64-5^\circ$, is obtained in the same way from *methyl α -chloroacetyl- β -aminocrotonate*, 4-sided, granular prisms from MeOH . From 16 g. (I) shaken 24 hrs. with 220 cc. of *N* NaOH , satd. with CO_2

and acidified with dil. HCl is obtained 12.7 g. of the free acid, yellowish granules from H_2O , m. 135° , gives with FeCl_3 a dark blue color gradually changing to brown. *Silver salt*, gray ppt. If (I) is allowed to stand 24 hrs. in 20 parts of fuming HCl it is converted into *diethyl 2,3'-bis-5,5'-thiololene-3-hydroxy-4,4'-dicarboxylate* (II), needles from alc., m. $102-3^\circ$, gives a green color with alc. FeCl_3 , sol. in concd. H_2SO_4 with intense blue-green fluorescence, hydrolyzed by boiling 1 hr. with alc. KOH to the free acid, granules from alc.- H_2O , decomp. $274-6^\circ$, gives a blue-green color with alc. FeCl_3 and an intense yellow-green fluorescence with H_2SO_4 . *Dipotassium salt*. The acid, heated some time with fuming HCl , goes over into the *lactone* (III), brownish needles from alc.- H_2O , decomp. $273-5^\circ$, gives no color with FeCl_3 , sol. in H_2SO_4 with intense yellow-green fluorescence, regenerates the acid on boiling with alc. KOH ; distd. dry with excess of lime, it gives the *4'-monocarboxylic lactone* (IV), needles from alc., m.

119.5° . *Ethyl 2,3'-bis-5,5'-thiololene-3-hydroxy-4-carboxylate-4'-carboxylic lactone* (V), from (I) heated on the H_2O bath with 4 parts PBr_3 , needles from alc., m. 158° , gives no color with FeCl_3 , sol. in H_2SO_4 with intense fluorescence, also obtained from (III) in hot alc. with HCl gas. *Diethyl 2,2'-methylenebis-5,5'-thiololene-3,3'-dihydroxy-4,4'-dicarboxylate* (VI), from 2 g. (I) in 40 cc. alc. with 2.5 cc. HCHO and 2-3 cc. fuming HCl , needles, m. 115° , gives a green color with alc. FeCl_3 , insol. in dil. NaOH , hydrolyzed by boiling alc. KOH to the free acid, needles from alc.- H_2O , m. 201° , gives a green

color with alc. FeCl_3 , does not lose H_2O with hot concd. HCl or H_2SO_4 . *2,2'-Benzal ester*, needles, m. $121-2^\circ$, gives a blue-green color with alc. FeCl_3 ; free acid, m. $161-2^\circ$. *Ethyl 3-phenylhydrazino-4-carboxylate*, from (I) and PhNHNH_2 on the H_2O bath, needles from alc., m. 109° , converted by warm dil. AcOH into the *3-indole ester* (VII), light yellow prisms from alc., m. $171-2^\circ$, gives a blue-green color with FeCl_3 in concd. H_2SO_4 ; free acid, needles from alc.- H_2O , decomp. $275-6^\circ$, gives on distn. with lime *3-indole 5-thiitolene*, needles from alc., m. $154-5^\circ$, quickly changes in the air, sol. in H_2SO_4 with red color, slightly reddens a pine splinter moistened with HCl , gives with NaNO_2 in AcOH the *N-nitroso derivative*, yellow needles from alc., m. $84-5^\circ$. *Ethyl 3-amino-5-thiitolene-4-carboxylate*, in 50% yield from (I) heated to boiling in 1 g. portions with 10 parts AcONH_4 , leaves from alc.- H_2O , m. 47° ; *chloroplatinate*, yellow needles, m. $188-9^\circ$. Attempts to diazotize the NH_2 ester in HCl gave a red-brown ppt. of approx. the comp. $\text{C}_{18}\text{H}_{20}\text{O}_8\text{N}_6\text{S}_2$; with PhN_2Cl in HCl there is obtained a dark red product which m. $145-6^\circ$. When the crude NH_2 ester prepd. as above is treated with dil. HCl there remains undissolved *diethyl 3,3'-iminobis-5,5'-thiitolene-4,4'-dicarboxylate*, green needles from alc., m. $105-6^\circ$, fluoresces strongly in alc.; free acid, needles from alc., decomp. $262-3^\circ$; *dipotassium salt*, needles. *3-Acetamino-5-thiitolene-4-carboxylic acid*, from the NH_2 ester hydrolyzed with alc. KOH and acidified with AcOH , difficultly sol. ppt.

CHAS. A. ROULLER.

Action of oxalyl chloride with derivatives of hydrazine. T. FOLPMERS. Univ. Leyden. *Rec. trav. chim.* 34, 34-77(1915).—F. studied the action of $(\text{COCl})_2$ on derivs. of NH_2NH_2 and the effect of the substituents on the course of the reaction. The literature on the action of acid halides on NH_2NH_2 derivs. is reviewed and it is shown (what has been noted by other chemists) that the nature of the substituents exercises a great influence in detg. the point at which the acid chlorides will attack. When the substituent is Me (i. e., MeNHNH_2) the Me end is more active than the other; but if Ph or any acyl group enters the NH_2NH_2 mol. the free NH_2 is more reactive. The difference between the effect of Ph and acyl appears in the secondary sym. mixed derivs. (like AcNHNHPh) where it is the NH having Ph that reacts. In MeNHNHPh the NH with Me reacts. The hydrazines containing acyl react in their tautomeric form as hydrazides. The method used has a large effect on the result. The nature of the solvent, the presence of H_2O or alk., excess of the NH_2NH_2 deriv. or not, whether the hydrochloride or the free base is used, is especially important with the sec. sym. mixed hydrazines. F. verified the above generalizations and extended them. **Primary derivs. of hydrazines with $(\text{COCl})_2$.** MeNHNH_2 (a) was obtained by treating benzalazine with Me_2SO_4 (Thiele, C. A. 5, 457), then with H_2O , the BzH was extd. with C_6H_6 , the aq. soln. was concd., and crystd. from EtOH . The base, b. $86.5-87^\circ$, was liberated from the sulfate by distg. with KOH . 4 mols. of MeNHNH_2 in dry C_6H_6 + 1 mol. $(\text{COCl})_2$ in dry Et_2O gradually gave a flocculent ppt. and then a viscous mass (b) which crystd. on standing in ice; recrystd. from EtOH it m. 228° . $(\text{CONHNHMe})_2$ was prepd. by von Bruning's method (*Ann.* 253, 13 (1889)), m. 228° (v. B. gave $221-1.5^\circ$) and m. unchanged when mixed with (b). In order further to identify (b) it was treated with HNO_3 gas in H_2SO_4 soln. to obtain the di-NO deriv., m. 153° (decompn.) (not 147° as stated by v. B.). The EtOH mother liquor from (b) treated with much Et_2O seps. crystals of $\text{PhCH:N}(\text{NMeCOCONMeN}):\text{CHPh}$, m. 210° , identical with that obtained by Backer (C. A. 6, 3264), and is probably produced by the action of $(\text{CONMeNH}_2)_2$ on BzH . The latter compd. is the unknown oxalyl- α -methylhydrazide and (b) is the known β -deriv. The α -deriv. is the

principal product, thus showing that $(\text{COCl})_2$ acts mainly on the methylated NH_2 group in (a). The condensation with BzH proceeds better with HCl than with HOAc . 4.32 g. PhNHNH_2 in dry Et_2O were treated slowly with 1.3 g. $(\text{COCl})_2$ in dry C_6H_6 , warmed an instant and filtered. The ppt. was washed with cold H_2O to remove $\text{PhNHNH}_2\cdot\text{HCl}$ and the (CONHNHPh) , remaining, recrystd. from EtOH , m. 277° (softens at 260°). In this case only the NH_2 was substituted by $(\text{COCl})_2$. 2 mols. acetylhydrazide (Curtius, Hofman, *J. prakt. Chem.* [2] 53, 524) + 1 mol. $(\text{COCl})_2$ in dry C_6H_6 on the H_2O bath for 4 hrs. sepd. *oxalylbis- β -acetylhydrazide*, $(\text{AcNHNHCO})_2$, silvery plates from hot H_2O , m. 283° ; the aq. soln. is acid, with $\text{NH}_3\text{-Ag}_2\text{O}$ it gives a pale yellow deriv. which is sol. in excess of NH_3 . In AcNHNH_2 only the NH_2 is substituted with $(\text{COCl})_2$. 2 mols. BzNHNH_2 (Curtius, Struve, *J. prakt. Chem.* [2] 50, 295) + 1 mol. $(\text{COCl})_2$ in dry C_6H_6 liberated HCl at once and sepd. a powder, *oxalylbis- β -benzalhydrazide*, $(\text{BzNHNHCO})_2$, microscopic needles from 95% EtOH , m. 278° ; it also crysts. as a hydrate with 2 H_2O . Neither form reduces $\text{NH}_3\text{-Ag}_2\text{O}$ or Fehling soln. In BzNHNH_2 only the NH_2 is substituted with $(\text{COCl})_2$. *Sym. secondary derivatives of NH_2NH_2 with $(\text{COCl})_2$* . $(\text{BzNH})_2$, obtained from $\text{NH}_2\text{NH}_2\cdot\text{H}_2\text{SO}_4$ + BzCl , was methylated with Me_2SO_4 in a faintly alk. soln. and gave *dimethylbibenzoylhydrazide*, softens 84° , m. 87° ; it was hydrolyzed by heating with strong HCl and concd. on a H_2O bath until it became sticky, the BzOH was partly volatilized, the residue was taken up in a little H_2O and more BzOH crystd. out; the *dimethylhydrazine hydrochloride* (c) was removed with Et_2O , beautiful white plates. 1 mol. (c) + 1 mol. $(\text{COCl})_2$ heated in C_6H_6 for 6 hrs. evolved HCl . The product was filtered off and treated with EtOH to remove unchanged (c); it was insol. in all org. solvents except PhNH_2 and gave on analysis figures corresponding to (c) + $(\text{COCl})_2$ — 2 HCl ; its mol. wt. could not be detd., it does not m. up to 365° , and is perhaps a homolog of hydrazioxazyl (Curtius, CO.NMe.NMe.CO

J. prakt. Chem. [2] 52, 223(1895)), in which case it would be CO.NMe.NMe.CO . Dibenzyldiazide (d) heated with 1 mol. $(\text{COCl})_2$ in C_6H_6 for 5 hrs. gave a combustible gas containing CO (purple color with AuCl_3) and CO_2 . Unchanged (d) was filtered off and the concd. soln. on cooling gave, finally, when crystd. from C_6H_6 , a compd. (e), $(\text{C}_6\text{H}_5\text{O}_2\text{N})_n$, softens 145° , m. $168\text{--}70^\circ$, of which the constitution was not detd. The C_6H_6 mother liquor residue when extd. with Et_2O gave a small amt. of a compd. $\text{C}_{14}\text{H}_{10}\text{N}_2\text{O}$ (f), white plates, m. $139\text{--}40^\circ$, which proved to be diphenylfurodiazole (Pinner, *Ber.* 27, 100(1894)). When repeated by boiling in C_6H_6 10 days (e) was not obtained but a large amt. of (f) was formed. It was thus shown that $(\text{COCl})_2$ acts as a dehydrating agent with (d). *Unsym. secondary derivs. of NH_2NH_2 with $(\text{COCl})_2$* . NH_2NMe_2 obtained by reducing dimethylnitrosoamine with Zn in AcOH , was converted into its hydrochloride and boiled with 0.5 mol. $(\text{COCl})_2$ in C_6H_6 until no more HCl was evolved, filtered, washed with EtOH , dissolved in H_2O , treated with KOH and extd. with Et_2O ; it gave *oxalylbis- β -dimethylhydrazide*, $(\text{Me}_2\text{NHNCO})_2$, m. 233° , which was identical with the same deriv. obtained in another way. MePhNNH_2 in EtOH soln. treated with HCl gas sepd. $\text{MePhNNH}_2\cdot\text{HCl}$ which, dried over NaOH , was heated with $(\text{COCl})_2$; *oxalylbis- β -methylphenylhydrazide*, $(\text{MePhNNHCO})_2$, m. $196\text{--}7^\circ$, seps.; with weak alks. it gives a yellow soln.; with HNO_3 , $\text{K}_2\text{Cr}_2\text{O}_7$ or FeCl_3 in concd. H_2SO_4 it gives a red coloration. $\text{Ph}_2\text{NNH}_2\cdot\text{HCl}$ similarly treated with $(\text{COCl})_2$, etc., gives *oxalyl- β -diphenylhydrazide*, $(\text{Ph}_2\text{NNHCO})_2$, m. $335\text{--}6^\circ$; insol. in solvents except PhNO_2 of which 150 cc. dissolve 3.4 g. *Mixed tertiary derivs. of NH_2NH_2 with $(\text{COCl})_2$* . 1 mol. *oxalylbis- β -dimethylhydrazide* (g) + 1 mol. $(\text{COCl})_2$ heated in C_6H_6 7 hrs. liberated HCl and changed from a white to a yellow powder. Recrystd. from H_2O unchanged (g) was sepd. and some CO_2 evolved. The yellow product $(\text{C}_6\text{H}_{11}\text{ON})_n$ was not decompd. in EtOH ; m. or decompn. p. $238\text{--}40^\circ$, mol. wt. 228. This product was shown not to

be tetraketopiperazine (Bornwater) similarly formed. With H_2O it gives $\text{CO} + \text{CO}_2 + \text{C}_6\text{H}_8\text{O}_4\text{N}_2$. Since 1,3,4-toluylenediamine (*h*) was valuable in detg. the CO.CO group in croconic leuconic acids *F.* boiled 1 mol. of the yellow compd. with 2 mols. of (*h*) in abs. EtOH. White needles, m. $335-45^\circ$ (decompn.), of 2,3-dihydroxy-6-toluquin-oxaline sepd. (Meyer, *Ber.* 30, 769(1897)). In another expt. which was heated 2 days there was a strong odor of Me_2NNH_2 which was identified. Oxalylbis- β -dimethylhydrazide was boiled with (*g*) in EtOH for 1.5 days but it was recovered unchanged. The constitution of the yellow compd. (*i*) is discussed below. Oxalylbis- β -methylphenylhydrazide (*j*) heated with $(\text{COCl})_2$ in C_6H_6 several days becomes red and seps. a violet substance. The red substance on repeated crystn. loses its red color and the rest was identified as (*j*). The red product is not decompd. by boiling C_6H_6 and is slightly sol.; the violet substance is insol. The violet compd. is sol. in acetone from which it crystals in KMnO_4 -colored crystals, but not enough was obtained for identification. The red product, $(\text{C}_6\text{H}_8\text{O}_4\text{N}_2)_n$, was purified by repeated crystn. from C_6H_6 , doubly refractive, rhombic crystals, m. $229-30^\circ$, decompg. to a red liquid, mol. wt. in acetone 420; $\text{C}_{18}\text{H}_{16}\text{O}_4\text{N}_4$ requires 352. The red product (*k*) becomes yellow when heated in aq. KOH and gives a white ppt. of (*j*) on adding AcOH; the mother liquors give CaC_2O_4 with $\text{Ca}(\text{OAc})_2$. The EtOH soln. of (*k*) decolorizes in 1 day and gives back (*j*); if HCl is added $\text{CO} + \text{CO}_2$ are evolved. By treating (*k*) with (*h*) as above the same 2,3-dihydroxy-6-toluquinoxaline was obtained; (*j*) was isolated from the mother liquor. 2 mols. (*k*) boiled with 1 of (*k*) in EtOH do not react. 0.306 g. (*k*) boiled with 1 cc. MePhNHNH_2 was decolorized at once and gave probably (*j*). The absorption spectrum of (*k*) shows a 2 cm. band at 512μ and a 1 cm. band at 494μ and the violet is completely absorbed. Oxalylbis- β -diphenylhydrazide does not react with $(\text{COCl})_2$ even at 120° or on the addition of CuCl or $\text{C}_6\text{H}_5\text{N}$. The action of ethyl hydrazoneacetate hydrochloride on $(\text{COCl})_2$ in C_6H_6 was studied. The reaction product $(\text{C}_6\text{H}_8\text{O}_4\text{N})_n$ was dissolved in CHCl_3 but was not obtained well crystd.; the mol. wt. could not be detd., and its constitution was not detd. MePhNHNH_2 reacting with $\text{ClCH}_2\text{CO}_2\text{Cl}$ in C_6H_6 gave HCl gas and a soln. from which the C_6H_6 was evapd. and the residue, *chloroacetmethylphenylhydrazide*, crystd. from Et_2O , as colorless needles, m. 75° . This was condensed in KOH-EtOH with the amides of $\text{ClCH}_2\text{CO}_2\text{H}$ or $\text{BrCH}_2\text{CO}_2\text{H}$; KCl was pptd. and *bismethylphenylaminodiacypiperazine* was sepd. with petr. ether after evapg. off the EtOH; cryst. plates, m. $244-5^\circ$. The results are summarized in part as follows: When there is one substituent in the NH_2NH_2 mol. the 2 halves can already be distinguished: that which contains the substituent and that which does not. *F.* examd. mono-derivs. containing Me, Ph, Ac and Bz. The principal reaction in the case of MeNHNH_2 with $(\text{COCl})_2$ is the formation of the β -Me deriv.; the α -Me deriv., $(\text{H}_2\text{NMeNCO})_2$, was isolated only as the BzH deriv. The mixed α,β -Me deriv., $\text{MeN}(\text{NH}_2)\text{COCONHNHMe}$, could not be isolated but it might be demonstrated by working on a larger scale. PhNHNH_2 gives only the β -Ph deriv. BzNHNH_2 or AcNHNH_2 both give the β -derivs. (95-6%) but the reaction was done on the H_2O bath. It seems that MeNH is a little more reactive than the NH_2 and the PhNH much less so. With BzNH and AcNH the NH_2 acts like an amide. The results with the sym. disubstituted derivs. are not simple. BzNHNHBz probably reacts as the tautomer $[\text{PhC}(\text{OH})\text{:N}]_2$ since it gives PhC:N:N:CPh.O . Other sym. di-derivs. were not studied

because of lack of time. With the unsym. disubstituted NH_2NH_2 derivs. one N lacked H and so only the β -derivs. could be formed. The 3 mixed tertiary derivs. of hydrazine obtained above were subjected to the action of $(\text{COCl})_2$ in C_6H_6 . Oxalylbis- β -dimethylhydrazide thus treated gave a yellow compd. (cf. (*i*) above), $\text{C}_8\text{H}_{12}\text{O}_4\text{N}_4$,

which may be a tetraketopiperazine, $\text{Me}_2\text{NN} \begin{array}{c} \diagup \text{CO.CO} \diagdown \\ \diagdown \text{CO.CO} \diagup \end{array} \text{NNMe}_2$. The decompn.

of (2) with boiling H_2O is not characteristic of known tetraketopiperazines; the decompn. is quant. and gives the parent hydrazide + CO + CO_2 , thus showing that the oxalyl group was eliminated. Likewise this 2nd oxalyl group reacts with 1,3,4-toluylenediamine to give 2,3-dihydroxy-6-toluquinoxaline and a mol. of the parent hydrazide which is not attacked by the diamine, which indicates that the 2nd oxalyl group is bound differently than the 1st. Although oxalylbis- β -dimethylhydrazide (I) does not react with the diamine the yellow compd. gives Me_2NNH_2 with excess of the diamine, so that (I) at the moment of its liberation does react and must accordingly have a different structure at this moment, i. e., a tautomer. Now the ordinary form of (I) could give the tetraketopiperazine, the $Me_2NN:C(OH)CONHNMe_2$ form may give $Me_2NN:C.CONNMe_2$ and the 3rd $Me_2NN:C(OH)C(OH):N.NMe_2$ may give

$Me_2NN:C\text{---}C:NMe_2$. The latter formula best explains the properties of

the yellow compd. (2) and is called dimeric *oxalic anhydride monodimethylsazone*. In treating oxalylbis- β -methylphenylhydrazide with $(COCl)_2$ a small amt. of a red compd. thought to be $MePhNN:C\text{---}C:NMePh$, i. e., dimeric *oxalic an-*

hydride monomethylphenylosazone, was obtained. If the two above hydrazides react as the tautomers it is clear that the $MePh$ deriv. gives the tautomeric form less easily than the di- Me_2 deriv. and that the di- Ph deriv. does not give the tautomer at all since it does not react.

The coagulation of albumin by electrolytes. W. D. BANCROFT. *J. Phys. Chem.* 19, 349-59(1915); see *C. A.* 9, 1339. E. J. C.

Some combinations of the type of chondroitin-sulfuric acid. FEDERICO ALZONA. Strassburg. *Arch. farm. sper.* 19, 221-34(1915); cf. *C. A.* 8, 3561.—Substances of the chondroitin-sulfuric acid type are widely distributed in the animal organism, and may be demonstrated in the skeletal muscles, the epithelial tissues and the secretions. They occur for the most part in combination with protein. The current view that a single chondroitin-sulfuric acid is present in the various organs but is combined in different ways, is no longer tenable. The comp. of prepn. obtained from the intestinal mucosa and from the prostate is widely different. Chondroitin-sulfuric acid probably contains a nitrogenous carbohydrate. A. W. DOX.

Experiments on diastase. TH. BOKORNY. *Allgem. Brau.-Hopfen-Ztg.* 55, 431-2 (1915).—Diastase (very difficultly sol. in water and of neutral reaction to litmus paper) was placed in contact with 1.0 N NH_4OH . It was observed that a quantity of NH_3 , corresponding approx. to about 10% of the diastase taken, disappeared. This added NH_3 could not be liberated by boiling alone; to liberate it $NaOH$ had to be added; this proves that the NH_3 is chemically combined. For comparison the NH_3 -absorbing capacity of blood protein, starch, peptone, muscle protein, egg albumen and casein was detd. and found to be 3.70, 1.36, 0.00, 2.55, 4.25 and 3.91%, resp. This behavior towards NH_3 suggests to B. the protein nature of diastase. It is dis-

tinguished from the albumins by the behavior to H_2SO_4 (normal soln.), of which none was absorbed. The protein nature of diastase was further disclosed by a digestion expt. with pepsin-HCl. The diastase was nearly completely dissolved and the soln. gave a bulky ppt. with phosphotungstic acid, while no pptn. occurred with satd. solns. of both ZnSO_4 and $(\text{NH}_4)_2\text{SO}_4$, thus indicating the formation of peptones.

Inactive lipase and the nature of its coenzyme. NOBUYOSHI UMEDA. King's College, London. *Biochem. J.* 9, 38-52(1915).—*Prep. of inactive lipase*: 2 kg. fresh pig pancreas, freed from visible fat, are minced and mixed with 4 l. glycerol. After 24 hrs. the mixt. is strained through 2 layers of muslin. Portions of 1 l. of ext. are dild. with 10 l. H_2O and allowed to stand 24 hrs. in the ice-box. The supernatant fluid is poured off and the ppt. again suspended in 10 l. H_2O . These washings are repeated 3 times. The flocculent ppt. is next suspended in an equal vol. alc. and filtered through a Pukall (see *Ber.* 26, 1159(1893)) porous clay filter. The ppt. is washed with acetone and ether. After this treatment it easily peels off in flakes from the filter and after drying *in vacuo* is obtained as a fine grayish white powder. *Prep. of coenzyme solns.*: The fluid decanted from the ppt. obtained on dild. of the pancreatic glycerol ext. with water, when boiled, filtered and concd., contains the coenzyme of lipase free from proteoclastic and other enzymes. To avoid the presence of glycerol, the coenzyme may also be prepd. by boiling 500 g. of minced pig pancreas with 500 cc. distd. H_2O for about 30 mins., and filtering after cooling. 620 cc. ext. which can be preserved under toluene is obtained. *Estimation of lipoclastic activity*: Olive oil is used as the zymolyte and the degree of lipoclastic activity is detd. by incubating the mixt. of enzyme and zymolyte for 17-20 hrs. and titrating the fatty acids liberated with 0.1 N KOH, using phenolph. as indicator. Enough alc. is added to give a 50% soln. The soln. of the ash of the coenzyme, when dissolved in HCl, possesses an activating power nearly equal to that of the original coenzyme. Nearly the whole of the activating substance passes through the dialyzing membranes. The ash of the incinerated dialysate, if dissolved in HCl, produces practically the same effect as the original dialysate. Very dil. H_3PO_4 activates inactive lipase, an inhibition being exerted if a certain limit is overstepped. CaCl_2 , if present in the digestive mixt. to the amt. of $M/7000$ to $M/1400$ has no effect on the lipoclastic. As the Ca content of 1 cc. of the ash soln. of the coenzyme corresponds to a $M/4116$ soln., it is probable that the action of the ash soln. is not due to Ca. The results with NaCl are contradictory. The activity of the pancreatic juice is in no way impaired by ordinary filtration; the enzyme exists in a sol. condition. In glycerol ext. of the pancreas, however, the material to which its lipoclastic activity is due occurs as a colloidal suspension and it requires a sol. coenzyme for its activation. The substances able to activate inactive lipase or to accelerate the action of active lipase may be divided into three groups: (1) The salts of Na, K, Ca, Ba, Mg; (2) org. and inorg. phosphates; and (3) bile salts and their derivs. Little is known with regard to their mode of action. In the case of the bile salts, cholic acid, their active constituent, probably acts directly on the enzyme (see Terroine, *Biochem. Z.* 23, 404 (1910); *C. A.* 4, 1990, 2327, 2512).

B. HOROWITZ.

Lignoceric acid from "carnaubon." O. ROSENHEIM AND H. MACLEAN. London. *Biochem. J.* 9, 103-9(1915).—The authors prepd. "carnaubon," a lipid, from ox kidneys and from horse kidneys according to Dunham and Jacobson's directions (*C. A.* 5, 1458) and hydrolyzed the products by alc. H_2SO_4 . Lignoceric, and not carnaubic acid, was obtained; hence the name "carnaubon" is a misnomer. "Carnaubon"

failed to yield palmitic or stearic acid, but phrenosinic acid ($C_{24}H_{40}O_2$) was isolated. The basic products of hydrolysis contained not only choline, but also an ether-sol. base identical with sphingosine. From these results, as well as the fact that the elementary compn. of different preps. of "carnaubon" is extremely variable, the authors conclude that kidney "protagon" represents a variable mixt. of lipoids, mainly of galactosides (cerebrosides) and sphingomyelin. In distinction from brain "protagon," it seems that sphingomyelin preponderates in kidney "protagon." B. HOROWITZ.

Researches on the inhibition produced by certain sera on the coagulating power of rennet. HAGEN C. THAYSEN. London. *Biochem. J.* 9, 110-31(1915).—The inhibiting effect of normal horse serum on the coagulating power of rennin is not due to 2 inhibiting substances, the true anti-body and the pseudo-antirennin (as supposed by Korschun, *Z. physiol. Chem.* 36, 141(1902)), nor to mere adsorption (cf. Hedin, *Biochem. J.* 1, 474, 484(1906); *C. A.* 4, 471). The [H] of normal horse serum is highly important for its inhibiting power. Normal rabbit serum behaves similarly to normal horse serum. B. HOROWITZ.

Counter diffusion in aqueous solution. GEORGE S. WALPOLE. Wellcome Physiol. Lab., London. *Biochem. J.* 9, 132-7(1915).—A re-interpretation of the work of Osborne and Jackson (*C. A.* 8, 2976). B. H.

Visible effects of the Schumann rays on protoplasm. W. T. BOVIE. *Botan. Gaz.* 59, 149-53(1915).—The Schumann region is the particular ultraviolet field with a wave-length of 2000-1250 (in Angstrom units). In this region of the spectrum the destructive action of the light is much more violent than in the regions of longer wave-length. This is probably due to the fact that the Schumann region is one of general absorption for nearly all substances. However, the absorption bands of such substances as egg-white and gelatin begin in the longer wave-lengths before the Schumann region is reached. B. exposed unicellular organisms to the Schumann rays and observed them microscopically during and after the exposure. The Schumann rays were produced by a discharge tube which was so made that it could be placed under the stage of a compound microscope in the position usually occupied by the condenser and other sub-stage attachments. When the discharge tube was in place, its fluorite window, through which the Schumann rays were emitted, was flush with the microscope stage. The Schumann light shone upward toward the microscope objectives. The organisms were exposed above the discharge tube on a special microscope slide which contained a window of fluorite (glass is opaque to these rays). The regular sub-stage attachments could then be swung into place and the organisms observed under high magnifications. The effects produced by the light were immediate. There was marked stimulation, followed by cytolysis, which, with sufficient exposure (usually less than 1 min. duration), terminated in death. The effect of the light was upon the organism itself and not upon the surrounding medium. Vesicle formation and the bursting of spores point to changes in osmotic relations, or to inhibition, which may be connected with the fact that the longer ultraviolet light waves have the power to break down proteins (cf. *C. A.* 7, 798). B. is of the opinion that the Schumann rays have a similar, and probably much greater, power. B. HOROWITZ.

Extreme alterations of permeability without injury. W. J. V. OSTERHOUT. *Botan. Gaz.* 59, 242-53(1915).—The permeability was measured by detg. the elec. resistance of living tissues of *Laminaria saccharina* (for the method used see *C. A.* 6, 2438). The results obtained show that the permeability of protoplasm may be greatly increased or diminished without injury. A rapid alternation of increase (amounting to 20% above normal) and decrease (amounting to 39% above normal) did not produce injury to the tissues. B. HOROWITZ.

Decrease of permeability due to certain bivalent cations. W. J. V. OSTERHOUT. *Botan. Gaz.* 59, 317-30(1915).—While none of the monovalent cations (except H) are able to decrease permeability all the bivalent cations so far investigated (Mg, Ca, Ba, Si, Mn, Co, Fe, Ni, Zn, Cd, Sn) are able to do so to a marked degree. B. H.

The body surface of flounders and its relation to the gaseous metabolism. SERGIUS MORGULIS. *Am. J. Physiol.* 36, 207-16(1915).—The body surface for *normal* flounders may be detd. by using the formula, $S = K\sqrt{W}$, where K has a value of 13.44, which corresponds closely with that for higher organisms. For *fasting* flounders the value for K changes. The O consumption bears direct relation neither to body wt. nor to body surface, diminishing per g. hr. but increasing per sq. cm. as the animal becomes larger. J. F. LYMAN.

The retarding effect of hydrogen ions upon fermentation. ERIK HAGGLUND. *Biochem. Z.* 69, 181-91(1915).—The retardation of fermentation by lactic acid is directly proportional to the H-ion conc. of the substrate. Temps. of between 20° and 35° have little effect, while between 35° and 40° there is a considerable increase in the retardation. C. J. WEST.

Reply to R. Höber: "Physical chemistry of vital staining." J. TRAUBE. Charlottenburg. *Biochem. Z.* 69, 309-12(1915); cf. Höber, *C. A.* 9, 467.

C. J. WEST.

Plant oxidation enzymes. OTTO H. K. BEGEMANN. Univ. Bern. *Arch. ges. Physiol.* 161, 45-232(1915).—The historical side of oxidation enzymes in plants is carefully discussed. Quant. reductase detns. were made by the "porcelain plate method" in which plant ext. was added to a drop of indigo on a porcelain plate until the indigo was decolorized, and by the "drop method" in which the dye soln. was dropped into 2 cc. of the plant ext.; the standard was the number of drops needed to decolorize a mixture of 1 cc. of a 1:1000 grape sugar soln. and 1 cc. of 1% NaOH. In the quant. estn. of peroxidase an aq. soln. of benzidine, satd. at 45°, is used. The reaction with $\text{Na}_2\text{S}_2\text{O}_8$ is considered as the normal action. The test may be carried out in a test tube or on filter paper. Catalase action was also compared with $\text{Na}_2\text{S}_2\text{O}_8$. The iodometric and volumetric methods were used, the latter being very suitable. A large number of plants were examd. for these 3 enzymes. In the 42 cases studied 40 contained peroxidase, 37 catalase, 18 reductase and 17 oxidase; a few contained tyrosinase. In most cases the amts. of peroxidase and catalase were about the same, 23 cases containing much of each, while in 10 cases only a small amt. of each was present. Only in the fungi was this found not true, as these contained very much catalase and no peroxidase. Oxidase and reductase are not as widely distributed and their action is not so marked. The physiol. enzymes are found principally in the mesophyll and other parenchymal tissue. Catalase is found in those places accessible to H_2O_2 and oxygenase, namely the veins and tracheids. The same is true for the peroxidase. The epidermis and its organs do not contain oxidation enzymes. Chlorophyll does not have an oxidation enzyme. It is shown that H_2O_2 may penetrate to those parts of the plant which are stained by eosin. Catalase and peroxidase are both equally influenced by temp.; raising the same increases the quantity of enzyme. Light of different wave lengths influences the enzymes differently. The series seems to be: red > violet > green > light = darkness > blue. During germination both enzymes increase and then remain rather const. The idea is put forth that "catalase" and "peroxidase" actions are only different manifestations of the same principle, "oxygenase," or that the 2 enzymes are identical. Expts. showed that they behave in nearly the same way towards temp., light and dialysis. The following explanation of enzyme action is given: The living cell contains a simply constituted aldehyde, RCHO , which is membrane permeable. The cell also contains a peroxide, ROOR , which is not capable of passing through

the cell membrane. If these two react to form an addition product, a "secondary peroxide," $RCH(OR)O. OR$, results, which is also incapable of passing through the cell membrane. This compd. may give off O, and is thus an oxidizing agent. This may be capable of oxidizing pyrogallol to purpurogallin. If, however, the "secondary peroxide" unites with H_2O_2 , $RCH(OH)O.OH$, the new compd., may be capable of reacting with other chromogens, such as benzidine. If an excess of H_2O_2 is present then O is liberated, with the appearance of the "catalase." The aldehyde itself may react with an easily reducible substance, thus acting as a "reductase." This may be represented as follows: "Oxygenase" + "(cell) peroxide" = "secondary cell peroxide;" "secondary cell peroxide" + chromogen = appearance of "direct oxidase;" "oxygenase" + H_2O_2 = "secondary (artificial) peroxide;" "secondary (artificial) peroxide" + H_2O_2 = appearance of "catalase;" "secondary (artificial) peroxide" + chromogen = appearance of "peroxidase;" "oxygenase" + dye = appearance of "reductase." B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Method of extraction of creatine and creatinine from the tissues and fluids of the body. A. COSTANTINO. Univ. Pisa. *Arch. farm. sper.* 19, 254-8(1915).—The tissue (40 g.) is finely minced, then shaken for 2 hrs. with 200-30 cc. of 2% $HgCl_2$ containing 1% HCl. After standing 2 hrs., the mixture is filtered through a dry filter, the Hg removed by H_2S and the latter by an air current. After neutralizing, the solution is concentrated on the water bath and the creatinine detd. colorimetrically.

A. W. DOX.

Comparative blood sugar determinations by polarization and reduction methods. CARL MAASE AND HERMANN TACHAU. *Z. klin. Med.* 81, 1-9(1914).—The reduction methods of Bertrand and Tachau were in good agreement with the polarization method in 11 cases. In the 12th case the polarization method yielded higher results; this is attributed to the presence of another sugar with less reducing power. One hr. after the ingestion of 100 g. fructose, the reduction methods gave higher results than were obtained by the method of polarization.

M. S. F.

Colorimetric determination of uric acid in urine. H. F. HÖST. *Z. klin. Med.* 81, 113-9(1914).—H. describes a modification of Riegler's method, wherein 2 cc. protein-free urine in a test tube with a 20 cc. mark are treated with 0.6 g. NH_4Cl and heated to 40°. After standing $\frac{1}{2}$ hr. or more, it is filtered through a small filter, and the ppt. washed 4 or 5 times with 2 to 3 cc. 20% NH_4Cl . The NH_4 urate is returned to the original test tube with 15 cc. boiling 5% HNH_2PO_4 . Four cc. 10% phosphomolybdic acid are added and the vol. made up to 20 cc. with the phosphate soln. This is heated to boiling, and after cooling is compared with the standard, prepared by treating 2 cc. (= 2 mg.) uric acid in Li_2CO_3 soln. with 4 cc. phosphomolybdic acid and HNH_2PO_4 in the manner described. This procedure was compared with the Hopkins-Wörner and the Folin-Macallum methods. Advantages over the Folin-Macallum method are claimed.

M. S. F.

Note on the Hopkins-Cole reaction for protein. H. G. D. BREIDAHN. Melbourne. *Biochem. J.* 9, 36-7(1915).—Due probably to the presence of an oxidizing agent (cf. Mottram, C. A. 8, 2403) the H_2SO_4 used invariably gave a brown or yellow-brown ring.

The following reducing substances added to the acid were found to increase the delicacy of the color formation: Mg, NaHSO_3 , Zn (powdered and granulated). B. H.

A new test for reducing sugars in urine. WILLIAM CRAMER. *Biochem. J.* 9, 156-60(1915).—The test depends upon the reduction of HgO in a weakly alk. soln. to metallic Hg. *Prepn. of reagent:* 0.4 g. HgO (red or yellow) and 6 g. KI are dissolved in 100 cc. water. This soln. is weakly alk. The alkalinity must now be so adjusted that 10 cc. of the reagent are neutralized by 2.5 cc. of 0.1 N acid, using phenolphthalein as indicator. This is done by titrating 10 cc. of the reagent with 0.1 N acid and, after the alkalinity of the reagent has thus been detd., adding the requisite amt. of 0.1 N acid or alkali to the bulk of the reagent. The reagent is a clear, colorless soln. which turns slightly yellow on heating and becomes colorless again on cooling. It must remain quite clear on boiling. *Test as applied to urine:* To 3 cc. of the reagent 0.3 cc. of urine is added and the mixt. heated to boiling. The test tube is removed from the flame and, after 30 seconds, the mixt. is acidified with a few drops of acetic acid. The test tube is at once held over ordinary print. If the urine is normal, a slight but distinct turbidity remains and print is clearly readable through the mixt. C. claims that the test is more sensitive than either Fehling's or Nylander's. Uric acid and creatinine do not interfere. B. HOROWITZ.

A greatly improved hemin test for blood, with notes on some recently proposed methods. W. BEAM AND G. A. FREAK. *Biochem. J.* 9, 161-70(1915).—The principle underlying this modification is the slow crystn. of hemin. *Procedure:* A small quantity of the suspected material is placed at the bottom of a flat As sublimation tube about 3 by 6 mm. and 35 mm. long. A few drops of acetic acid containing from 0.01 to 0.1% NaCl are added, and a very fine cotton thread adjusted so that its upper end is near the top of the tube and the lower end reaches to the bottom of the liquid. The thread should be everywhere in contact with the tube, to which it adheres readily by being moistened with the liquid. The adjustment is made by means of a glass rod, one end of which is drawn out for the purpose. The tube is now placed in a rack and allowed to remain until crystn. occurs. The clear liquid, filtered by its passage through and along the cotton thread, is slowly drawn up, by capillary action, to the mouth of the tube. Complete evapn. usually takes from 12 to 24 hrs. Crystals usually begin to appear on or near the upper half of the thread, and are sufficiently large to be distinguishable in about 1 hr. with a power of 75 diameters. Ultimately they become so large that, in place of requiring a magnification of 250 to 300 diameters, they may readily be seen with one of 25 diameters. Of the solvents used, acetic acid was found to be the best. Forms of halides other than NaCl showed no advantage. B. HOROWITZ.

Simple test for sugar in the urine. L. DE JAGER. *Ph. Praxis; Boll. chim. farm.* 54, 39(1915).—Five cc. urine are treated with 10 drops of a soln. (prepd. 24 hrs. previously) of 30 g. Ca(OH)_2 and 100 cc. H_2O ; 5 drops of a 10% CuSO_4 soln. are then added. The red or violet coloration of the ppt. which is formed after a short time indicates the presence of sugar. The limit of sensitiveness is approx. 0.1%. H. S. PAINE.

Simple and accurate method for estimation of sugar in blood. E. B. KNEER. *Kansas City. Missouri State Med. Assoc. J.* 12, No. 4(1915); *J. Am. Med. Assoc.* 64, 1452-3.—The solns. required are 2% $\text{K}_2\text{C}_2\text{O}_4$, 10% K_2CO_3 , 1% glucose, and picric acid (conc. not given). Two-tenths cc. of blood is taken up in a 1 cc. pipet (graduated in tenths) and transferred to a test tube in which has been placed previously about 0.5 cc. of the $\text{K}_2\text{C}_2\text{O}_4$ soln. and well mixed; H_2O is now added to bring the mixt. up to 1 cc., then 1.5 cc. picric acid soln. gradually with thorough mixing. The contents of the tube are then centrifuged or filtered and 1 cc. of the clear yellow liquid transferred to a test tube and evapd. to a few drops. To the conc. liquid 0.5 cc. K_2CO_3 is added and this evapd. to a few drops. The presence of sugar is indicated by the

dark red-brown color of the soln. which is now dild. to 10 cc. A parallel test is made on the 1% glucose and the % of sugar estimated by color comparison. Cf. Lewis and Benedict, *C. A.* 9, 638.

L. W. RIGGS.

Improved technic for the preservation of brains. A. GIANNELLI. *Polislinico* 22, No. 3(1915); *J. Am. Med. Assoc.* 64, 1537.—After removal of the meninges the brain was placed in 5 liters of 5 or 10% HCHO for 15 days, with cotton on the floor of the vessel. It was then placed in alc. for the same length of time, after which it was immersed in glycerol for a month; it was removed then to a slanting shelf of glass to drain. Brains thus treated show no changes in 7 years, while with other methods they become hard or brittle unless permanently covered with fluid. L. W. RIGGS.

Application of the Van Slyke amino-nitrogen determination to the diagnosis of cancer. OTTO LOWY. Newark. *J. Am. Med. Assoc.* 64, 1559-60(1915).—L. points out the difficulties in making tests by the Abderhalden thimble method, and recommends the use of the app. devised by Van Slyke for measuring the amino-N content of the blood. The cancer substrate is prepd. in the same manner as for the thimble method and then dried and added to the suspected serum. Another tube contains the serum alone. Both are covered with toluene and incubated 24 hrs. The increase in the amt. of amino N liberated from the serum plus substrate over that from the serum alone indicates the presence of a proteolytic enzyme in the serum. Care must be taken to rid the substrate of all sol. proteins and to test it to det. if any N is evolved. By this method 35 out of 42 cases of cancer gave positive results; 34 out of 40 nonmalignant cases gave negative results.

L. W. RIGGS.

Estimation of very slight amount of free acid or alkaline substance in liquids of animal or vegetable origin. A. STUTZER AND W. HAUPT. Univ. Königsberg. *Biochem. Z.* 69, 305-8(1915).—Small amts. of free acid may be detd. by adding to 250 cc. of the fluid to be examd. 25 cc. 0.2 *N* NaOH and 1 g. NH_4Cl and distg. off the NH_3 liberated into 0.2 *N* H_2SO_4 . The difference between the amt. thus formed and the amt. formed with distd. H_2O is a measure of the free acid. A second method consists in adding 25 cc. I soln. (20 g. KI and 5 g. KIO_3 in 500 cc. H_2O) and a little starch and titrating with 0.01 *N* $\text{Na}_2\text{S}_2\text{O}_3$ until the blue color disappears. The end point may be made more sensitive by dilg. with CO_2 -free H_2O . In the same way alkalis may be detd. by warming with 0.01 *N* H_2SO_4 to remove CO_2 , adding starch and I soln. and titrating with $\text{Na}_2\text{S}_2\text{O}_3$.

C. J. WEST.

Clinical calorimetry. I. A respiration calorimeter for the study of disease. GRAHAM LUSK. Russell Sage Inst. and Cornell Univ. Med. College. *Arch. Intern. Med.* 15, 793-804(1915).—II. The respiration calorimeter of the Russell Sage Institute of Pathology in Bellevue Hospital. J. A. RICHE AND G. F. SODERSTROM. *Ibid* 805-28.—III. The organization of a small metabolism ward. FRANK C. GEPHART AND EUGENE F. DU BOIS. *Ibid* 829-34.—Introduction and description of respiration calorimeter and organization of metabolism ward. IV. The determination of the basal metabolism of normal men and the effect of food. FRANK C. GEPHART AND EUGENE F. DU BOIS. *Ibid* 835-67.—The metabolism of 7 normal men was studied. The av. metabolism at perfect rest (14-18 hrs. after the last meal) was 34.8 cal. per sq. meter of body surface. The greatest deviation from this av. was 11%. Metabolism is proportional to body surface and not to body weight. The methods of indirect and direct calorimetry agree in 2 and 3 hr. periods and, in health, in hourly periods. The method of indirect calorimetry (O_2 consumed as basis) gives best results in short periods. In these direct calorimetry is made inaccurate by uncertainty as to the correct specific heat of the body and also to the differences in the rate of change of temp. of different parts of the body. Ordinarily the rectal temp. is taken as that of the body, but in typhoid fever better results are obtained with surface thermometers. The ingestion of 200 g. of

glucose or of a mixt. of glucose and dextrin or of a casein meal containing 10.5 g. N increase the heat production by about 12% in a period of 3-6 hrs. V. The measurement of the surface area of man. DELAFIELD DU BOIS AND EUGENE F. DU BOIS. *Ibid* 868-81.—The surface area of the different parts of the body was detd. by making a mold of the surface by pasting paper on tight-fitting underwear. Various regions of the body were marked on the mold, which was then removed, cut in pieces and coated with paraffin. Patterns of these pieces were printed on photographic paper and the patterns cut out and weighed. The area was then readily calcd. The hands were enclosed in gloves which were then coated with paraffin. The area of the region back of the ears and of the penis and scrotum was detd. by measurement. A large number of measurements of the linear dimensions of parts of the body was made. From these, attempts were made to derive formulas for the area of the given region in terms of the linear dimensions and a const. Those which gave smallest deviations from the normal were accepted. These are: *Head*, including ears, AB 0.308, A around vertex and chin, B around occiput and forehead, just above eyebrows; *arms*, $F(G + H + I)$ 0.558, F outer end of clavicle to lower border of radius, G circumference at upper border of axilla, H largest circumference of forearm, I smallest circumference of wrist; *hands*, JK 2.22, J lower posterior border of radius to tip 2nd finger, K circumference of open hand; *trunk*, including neck, breasts in female and penis and scrotum in male, $L(M + N)$ 0.703, L suprasternal notch to upper border of pubes, M circumference of abdomen at level of umbilicus, N circumference of thorax at level of nipples in male and just above breasts in female; *thighs*, $O(P + Q)$ 0.508, O superior border of great trochanter to lower border of patella, P circumference of thigh just below level of the perineum, Q circumference of hips and buttocks at level of trochanters; *legs*, RS 1.40, R from sole of foot to lower border of patella, S circumference at level of lower border of patella; *feet*, $T(U + V)$ 1.04, T length of foot, U circumference at base of little toe, V smallest circumference of ankle. The difference between the areas calcd. from the above formulas and those actually detd. by measurement were rarely more than 10% and usually much less. Cf. C. A. 9, 1801. I. GREENWALD.

Landau's color test for serodiagnosis of syphilis. JOHN A. KLÖMER. Phila. J. Am. Med. Assoc. 64, 1461-3(1915).—Landau's first method was to add 0.2 cc. serum to 2.5 cc. of a reagent prepd. by mixing 5 drops tincture of I with 10 cc. of paraffin oil, and setting aside in a dark place for from 5 to 15 hrs. He claimed that syphilitic serum decolorizes the mixt. while a reddish yellow color persists with normal serum. Later the technic was modified by using a 1% soln. of I in CCl_4 , 0.2 cc. of the fresh clear serum being added to 0.1 cc. of the reagent. Syphilitic serum gave a clear, transparent yellow and nonsyphilitic serum gave an opaque, whitish gray fluid. K. found that both normal and laetic serums and cerebrospinal fluid gave entirely unsatisfactory results with the iodized petrolatum, and with the I in CCl_4 reagent. The error of this test is not only in the low % of correct positive results, but is especially evident in the high % of false positive reactions with non-luetic serums. L. W. RIGGS.

C. BACTERIOLOGY.

ERNEST D. CLARK.

Studies on *Rhizopus* species. II. Physiological. J. HANZAWA. Sapporo. *Mycol. Centrbl.* 5, 257-81(1915).—With the exception of *Rh. nigricans*, practically all of the species ferment glucose, maltose, galactose, fructose, mannose and dextrin, but not lactose, xylose, arabinose, rhamnose, α - and β -glucosides or mannitol. Sucrose, raffinose and inulin are fermented by some species but not by others. All of the species liquefy gelatin, imparting to it a reddish brown color. All coagulate milk, and all except *Rh. nigricans* liquefy starch paste. The possibility of distinguishing the various species by physiological means seems very remote. A. W. DOX.

Nitrogen assimilation in *Aspergillus*. W. ZALESKI AND D. PIJUKOW. *Ber. deut. botan. Ges.* 32, 479-83(1914).—In the presence of glucose and the necessary mineral salts the authors show that *Aspergillus* takes up NH_4 salts more readily than amino acids. Histidine is not utilized at all. Some of the other amino acids, grouped in their order of assimilation, are phenylalanine < leucine < glycine < alanine < aspartic acid. If a mixt. of NH_4 salts and amino acids is given, an increased quantity of the latter is taken up. By substituting glycerol for glucose, N in form of alanine is used just as well as in form of NH_4 salts. B. HOROWITZ.

The destruction of paraffin by *Bacillus prodigiosus* and soil organisms. R. GREIG-SMITH. *Proc. Linnean Soc. N. S. Wales* 39, 538-41(1914).—Dried blood, casein and kieselguhr were coated with paraffin and were then treated with suspensions of *B. prodigiosus* and of some soil organisms. In a month at 28° *B. prodigiosus* caused a loss of extractable paraffin of 14%; the soil organisms a loss of 49%.

M. X. SULLIVAN.

Protein transformations in yeast. II. Influence of medium upon the protein decomposition in yeast. W. ZALESKI AND W. SCHATALOFF. *Univ. Cracow. Biochem. Z.* 69, 294-304(1915); cf. *C. A.* 8, 1136.—The unfavorable action of monovalent alcs. (MeOH , EtOH , $\text{iso-C}_4\text{H}_9\text{OH}$, $\text{iso-C}_5\text{H}_{11}\text{OH}$, allyl alc.) upon yeast proteolysis becomes evident in concns. of more than 4%. The action of aromatic alcs. (PhCH_2OH) is more unfavorable. Phenols also have a retarding effect. The most noticeable effect was obtained with phloroglucinol. Of the alcs. present in the fermentation liquid, only EtOH is present in sufficient concn. to influence the course of the proteolysis. The proteolytic enzymes of yeast act best in a slightly acid medium. Dil. solns. of HCl and HCO_2H have no effect, while other acids, like H_3PO_4 , oxalic, lactic, pyruvic, AcOH and citric exert favorable effects up to certain concns.; above them. retarding effects. No relation was found between the H-ion concn. and the work of the proteolytic enzymes. Alkalies are unfavorable. This explains the unfavorable action of certain salts. The effects of many substances were studied, detns. of protein, peptone, NH_4 - and basic-N being made. C. J. WEST.

The morphological variability of *Mycoderma vini*. R. PEROTTI. *Rome. Atti accad. Lincei* 23, II, 423-6(1914).—Expts. showed that variations in the conc. of glucose, in the source of the C and N, and in the acid and alc. content of the nutritive solns. determine the large morphological variations of *Mycoderma vini*. Under variations of this kind (cf. original for details as to media used and details of results) the cells may become smaller or may increase up to double their normal size; the cell form may become elongated, bacillus-like, round, rod-shaped or be round on one side and prolonged on the other. E. J. WITZEMANN.

Synthesis of protein in yeast. W. ZALESKI AND W. ISRAELSKY. *Ber. deut. botan. Ges.* 32, 472-9(1914).—The authors studied the synthesis of protein in yeast, using various media. The protein content remains const. during fermentation in pure sugar soln. (cf. Ivanov, *Z. physiol. Chem.*, 42, 464). Asparagine and glutamic acid support protein synthesis, while glycocoll and phenylalanine do not. B. HOROWITZ.

D. BOTANY.

CARL L. ALSBERG.

The physiological value of the reserve substances in chestnuts. C. MANICARDI. *Staz. sper. agrar. ital.* 47, 633-6(1914).—The reserve substances are always much in excess of the requirements for a normal germination. The whole action of the reserve substances in germination is upon root development. The chestnut can exist for a certain length of time by means of photosynthetic assimilation alone.

L. J. GILLESPIE.

The germinative force of the seeds of *Cuscuta trifolii* imbedded in stable manure, in mineral fertilizers and in the soil. A. MORETTINI. *Stas. sper. agrar. Ital.* 47, 433-51 (1914); *Chem. Zentr.* 1915, I, 498.—Comparative germination expts. showed that the seeds of clover silk soon lose their germinative force in mineral fertilizers; in dry soils (planted 15-20 cm. deep), although their germination is stimulated at first, the germinative force decreases rapidly after about 3 months. In stable manure it is completely inhibited after a short time so that the view of various investigators that the passage through the digestive tract and the excretion with the feces have no influence on the germinative power, must be considered correct. C. F. MILLER.

The acidity of Sphagnum and its relation to chalk and mineral salts. MACGREGOR SKENE. *Ann. Botany* 29, 65-87(1915).—There is variation in acidity and in sensitivity to chalk in the different species of *Sphagnum*. A correlation exists between the degree of acidity and degree of sensitiveness, though the connection between the two is indirect. *Sphagna* thrive in acid solns.: the injurious effect of chalk, and of alkalis in general, is due to the substitution of an alk. for an acid reaction. Mineral solns. are generally physiologically harmless, but may be ecologically harmful. *Sphagnum* utilize, in growth, bases held by the acid compds. of the cell walls. B. HOROWITZ.

Relation between the concentration of nutrient solution and the rate of growth of plants in water culture. WALTER STILES. *Ann. Botany* 29, 89-96(1915).—If the nutrient solns. in water-culture expts. are changed frequently, so as to maintain more nearly a const. compn. of the soln., the conc. of the soln. may vary considerably without producing much effect on the rate of growth of the cultures as measured by the dry matter produced within a given time. Below a certain concn., however, there seems to be an indication that the rate of growth becomes less. Frequent changing of the nutrient soln. of water cultures produces decidedly better growth of the plants. It is necessary to calculate the probable error of the results obtained in expts. on water-cultures in order to det. the significance of differences between results from different sets of cultures. B. HOROWITZ.

Effect of salt on the growth of *Salicornia*. A. C. HALKET. *Ann. Botany* 29, 143-54(1915).—*Salicornia oliveri*, Moess., and *Salicornia ramosissima* grow better in the presence of NaCl than they do in its absence, the greatest growth occurring in the presence of 2 to 3% of the salt. Higher percentages decrease the growth of the plants. The effect of NaCl on the growth of *Suaeda maritima* is not so marked. Plants grow as well in its absence as when a small quantity (1%) is present. Growth decreases with increase in the amt. of salt above 1%. *Salicornia ramosissima* and *Suaeda maritima* can resist the presence of a large amt. of NaCl, as is seen from "pan" expts., when the plants remain alive and green even if the salinity of water in soil rises at times to 17%, though they are not able to grow. The growth of *Glyceria maritima* is decreased with the increase of the salinity of the soil. B. HOROWITZ.

Respiration of living and dead wheatbuds. S. KOSTYCHEW, W. BRILLIANT AND A. SCHELOVMON. *Ber. deut. botan. Ges.* 31, 432-41(1913).—The O intake of living and dead wheat buds is greatly reduced by a slight lowering of the air supply. Na₂HPO₄ has no influence on the CO₂ output and O₂ intake of living wheatbuds; sugar solns. increase both the CO₂ and O₂, though r. q. remains constant. In the case of dead wheatbuds, sugar solns. increase only the CO₂ output, and this even under excellent aërating conditions; here the r. q. is considerably increased. B. HOROWITZ.

Further researches into the chemical organization of the cell. W. RUHLAND. *Ber. deut. botan. Ges.* 31, 553-6(1913).—(For former work see *Biol. Zentralb.* 33, 337.) The fact that many plant cells show an acid reaction cannot be explained on the basis of non-permeability of the enveloping membrane of protoplasm, since the membrane

is readily permeable to acids. Some other factor must be ascribed to the cell. In several cases R. has studied the acidity of cells by the introduction of indicators.

B. HOROWITZ.

Occurrence of "inklusen" in the leaves of *Pistacia lentiscus* L., and remarks concerning the anatomical structure of these leaves. T. F. HANAUSEK. *Ber. deut. botan. Ges.* 32, 117-22(1914).—With the exception of those cells of the mesophyll which contain Ca oxalate, all the other cells of the *Pentiscus* leaves contain "inklusen;" those with FeCl₃ become dark green to black, with KOH violet, with conc. H₂SO₄, plus vanillin in HCl, red.

B. HOROWITZ.

Formation of anthocyanin in the leaves of the rose. A. M. LÖWSCHIN. *Ber. deut. botan. Ges.* 32, 386-92(1914).—Guilliermond's views (cf. C. A. 8, 2740) on the formation of anthocyanin are held to be erroneous. The following views are advanced: In early development one observes thick clusters of granules and threads near the nucleus. The granules and threads gradually increase in size. The introduction of light leads to the development of a red color; so long as light is absent the granules remain colorless. Along with increase in size there proceeds a gradual union of individual elements, and this ultimately leads to the building of vacuoles containing the anthocyanin. The part played by the mitochondria cannot yet be stated. The granules and threads may be regarded as the mother substances of anthocyanin, and this, under the influence of the nucleus, is synthesized in the cell.

B. HOROWITZ.

Formation of anthocyanin and contents of the ash. A. CZARTKOWSKI. *Ber. deut. botan. Ges.* 32, 407-10(1914).—N deficiency in the mineral food of green plants furthers anthocyanin formation. For the effect of S, P, K, Ca, etc., see tables in the original.

B. HOROWITZ.

Chloroplast formation. A. P. PONOMAREW. *Ber. deut. botan. Ges.* 32, 483-8(1914).—P. attacks the problem from a colloid chem. standpoint. The materials used were *oedogonium*, *vaucheria*, *spirogyra*, etc. The living chloroplasts always appear homogeneous. High temp. and heavy metallic salts cause their coagulation. The substance of the chloroplast has selective permeability; at death it loses its osmotic properties and becomes permeable to sugar. The same colloidal structure must be ascribed to chloroplasts as to protoplasm, though the viscosity of the former is greater than that of the latter.

B. HOROWITZ.

The respiration of sea algae. E. PAUTANELLI. *Ber. deut. botan. Ges.* 32, 488-98(1914).—P. detd. the respiratory quotient of various algae from the Gulf of Naples. At the same time detns. were also made of the fluctuations in sugar content by micro- and macrochemical methods. The r. q. varies so considerably that no general conclusions can be drawn. The r. q. is lower the greater the O content of the water.

B. HOROWITZ.

The chemical action of dry-rot on wood. C. WEHMER. *Ber. deut. botan. Ges.* 32, 601-8(1914).—In studies with pine wood, undergoing dry rot, and of which some of the oxalic acid content could be extd. by boiling water, the author found that such wood cannot be deprived of acidity. This is also true of wood not decayed, though to a less extent. The action of the fungus, then, seems to be accompanied by an increase in acidity.

B. HOROWITZ.

Chemical modifications of plant organs undergoing autofermentations. M. MOLLARD. *Compt. rend.* 159, 512-4(1914); *Expt. Sta. Record* 32, 427.—Sections of squash tissue under sterile conditions used up sugar more quickly under aerobic than under anaerobic conditions. Amino N remained const. in air, but increased under anaerobic conditions. Amido N quickly disappeared and NH₃ increased under both conditions. Autofermentation may be distinguished by the method by which sugars are utilized as well as by the transformation of N materials.

J. J. SKINNER.

The action of various electrolytes on the grain of *Avena sativa*. F. PLATE. *Annali di botanica* 12, 261-343(1914); *Bull. Agr. Intelligence* 5, 1429.—The effect of the different ions of acids, bases, and salts was investigated. The strengths of the solns. used were N , $0.5 N$, $0.2 N$ and $0.1 N$ and the period allowed for absorption was 2 hrs. Observations were made of substances which accelerate or retard germination and on the effect of imbibition on the external morphological characters of the seedlings with special reference to the size of the shoot and root and the fresh and dry wt. of the seedling. The quantities of salt absorbed were likewise detd. Cf. C. A. 8, 360; 9, 1070.
M. X. SULLIVAN.

Certain constituents of lupine seeds. G. MUECK. *Landw. vers. Stat.* 83, 393-416(1914).—The seeds of blue, yellow and white lupines were found to be rich in diastatic, in glucoside-splitting and in peptone-splitting enzymes. An enzyme, capable of fermenting urea, is also present. The blue lupine was found to contain an agglutination enzyme, phasin. The technical and toxicological importance of these enzymes are discussed.
E. H. WALTERS.

Alcohol oxidation by phanerogamous plants. W. ZALESKI. Univ. Cracow. *Biochem. Z.* 69, 289-93(1915).—From 27 to 72% of the alc. taken up by the plants was oxidized. Whether the alc. was completely burned or was oxidized to organic acids was not detd.
C. J. WESS.

The artificial absorption of liquids in plants by means of the aerial part. C. ACQUA. Bot. Ist., Rome. *Atti accad. Lincei* 23, II, 78-84(1914).—The ordinary way of studying the absorption of various compds. by plants is to place the roots in solns. A. had previously shown that the roots themselves have special effects and tried the effects of solns. on the aerial stems without roots. Young mulberry plants (*M. albus*) were cut off at the base of the leaf stalk and transverse cuts were made into the lower end of the stem. Stems so prepared were placed in 2.5, 5 and 10% glucose solns. Considerable absorption took place at once; in the 5% soln. 25 drops (1 drop = 0.034 g.) were absorbed in 12 hrs. When compared with control plants it was found that the plants thus treated acquired a higher resistance to a subsequent treatment which is normally unfavorable to mulberry plants. This increased resistance was greater in the cooler seasons but was quite significant even in the warmer season. The stems show white specks due to solid glucose. The quantity absorbed is inversely proportional to the conc. Expts. with sucrose gave the same result. With NaCl soln. in a conc. equiv. to 5% glucose there was no absorption, showing that the effect is not due to the osmotic properties alone. With 50 and 25% aq. solns. of glycerol immediate wilting took place, but when the stems were restored to H_2O their turgescence reappeared. Solns. of H_3BO_3 and salicylic acid cause rapid death of the plants; the part above the incisions was most quickly affected. The toxic limit with H_3BO_3 is about 1% soln. which the plants could tolerate 3-4 days, after which they died. This method is thought to have many advantages for the study of vegetal biology.

E. J. WITZEMANN.

E. NUTRITION.

PHILIP B. HAWK.

NORMAL.

The influence of certain vegetable fats on growth. E. V. MCCOLLUM AND MARGUERITE DAVIS. Univ. Wisconsin. *J. Biol. Chem.* 21, 179-82(1915).—Rats were fed on a fat-free diet of casein, lactose, dextrin, agar-agar and salts until they were in an enfeebled condition (20-25 weeks). The ration was then changed to fat-free ration 50% and 50% plant product: corn meal, wheat embryo, entire wheat kernel, rye or rolled oats. The corn meal had a pronounced stimulating effect on growth, similar to that observed with animal fats. Wheat embryo exerted similar action

whereas entire wheat kernel arrested further decline but brought about no increase in wt. Rye and rolled oats were not effective in stimulating growth. While the addition of 5% butter-fat to a fat-free diet has marked stimulating action, 50% of corn is much superior; however, the addition of 5% wheat or 5% corn is not sufficient to prevent decline and death. Expts. were also performed in which the fat-free diet was changed to a mixt. of dextrin, Ca lactate and either dried pig heart or kidney. Very temporary benefit was derived from feeding the pig heart as compared with the kidney, but rapid growth occurred when the dried kidney replaced the heart tissue in the diet. The differences observed in the effects of wheat, rye and oats "may well be due to quant. differences in the yield of the unknown accessory substances under consideration rather than to an entire absence of the same. The possibility should also be emphasized that there may be carried by certain of the grains substances sufficiently toxic to cause injury to animals in such an enfeebled condition." A. P. LOTROP.

Utilization of calcium and phosphoric acid compounds by the animal organism. III. Utilization of the chief phosphoric acid compounds by ruminants. G. FINGERLING. *Landw. Versuchs. Sta.* 86, 75-114(1915).—Expts. with lambs in which P was supplied as casein, phytin, lecithin, nuclein, Na nucleate, and Na_2HPO_4 . No essential differences in the results were observed, and the conclusion is drawn that the unsatisfactory results obtained with some foods cannot be due to the form of the P, but to the nature of the food itself. E. H. WALTERS.

Does the cholesterol of the food have any influence upon the cholesterol excretion through the bile? L. D'AMATO. Univ. Naples. *Biochem. Z.* 69, 217-24(1915).—Dogs fed with lipoid-rich diet show a const. though small increase of cholesterol and bile salts in the bile. The slight increase does not justify the supposition that the bile is the principal excretory path for cholesterol nor that the cholesterol of the food is largely changed into cholic acid and thus excreted as bile salts. C. J. WRIGHT.

To what extent is plant protein of the food utilized by the animal body? I. H. BORUTTAU. Berlin. *Biochem. Z.* 69, 225-44(1915).—The value of cereal-protein in bread is somewhat greater than in the isolated form. The same is true of the alc.-sol. part, the gliadin. The availability of the N-substances in spinach is very high. The value of gliadin is increased by the addition of a small amt. of spinach powder. The same is true of the addition of the powder or oat straw, though the straw contains only 0.96% N. The N of bran, as far as it is resorbed, is very suitable for building up the body protein. C. J. WRIGHT.

ABNORMAL.

Digestion and absorption of protein and fat in normal and depancreatized animals. ERNEST W. H. CRUICKSHANK. University College, London. *Biochem. J.* 9, 138-55 (1915).—In normal dogs the N utilization on a high protein diet varied from 95 to 96.5%, while on a low protein diet it was 88%. Fat utilization on a high fat diet was 97 to 98.9%, on a low diet 87.1%. In partially depancreatized animals there is very little difference in power of assimilation, whether the piece of gland is grafted in the abdominal wall or left *in situ*, but the addition of pancreas to the diet exerts a most favorable effect in both cases. Total depancreatization produces severe diabetes which is usually fatal in about a week. This condition is prevented by performing the operation in 2 stages, the first being a partial depancreatization. Immediate depancreatization without pancreas in the diet results in a loss of 22% of N and 67.4% of fat. The addition of pancreas increases the utilization of N to 92% and of fat to 70-88%.

B. HOROWITZ.

A study of the metabolism in experimental diabetes. V. H. K. MOORHOUSE, S. W. PATTERSON AND M. STEPHENSON. University College, London. *Biochem. J.* 9,

171-214(1915).—In exptl. diabetes the increase in metabolism amounts to 15-20% on an average, and this increases with the severity of the condition. Whereas under normal conditions the respiratory quotient increases with the intake of glucose, this increase is markedly diminished or is entirely absent after the removal of the pancreas, thereby indicating an incomplete oxidation of sugar. The increase in the excretion of acetone substances parallels the increase in the *D:N* ratio and the total metabolism, suggesting that the phenomena are expressions of a similar disturbance of protein metabolism, which is secondary to the impairment of sugar utilization. B. H.

Influence of calcium salts upon phlorhizin diabetes. MARTIN JACOBY AND RUDOLF A. P. ROSENFELD. Berlin. *Biochem. Z.* 69, 155-61(1915).—High and very high doses of Ca lactate have an immediate effect upon phlorhizin diabetes; the excretion of sugar and acetone falls rapidly to 0 or nearly 0, and the N decreases. The injury to the kidneys, recognized by the presence of protein and blood in the urine, soon produces death. The same effect is obtained if the Ca salt is given before the phlorhizin. Similar results were observed by using CaCl_2 . The decrease in urine sugar is accompanied by a parallel decrease in the blood. Thus the sugar formation by phlorhizin is retarded by the action of Ca salts. C. J. Wær.

Relation of lactic acid to the carbohydrate metabolism. III. The formation of lactic acid in human diabetes. OTTO VON FÜRTH. *Biochem. Z.* 69, 199-216(1915); cf. C. A. 8, 3456.—Using the aldehyde method for detg. lactic acid, the post-mortal capacity for forming lactic acid by the muscles and liver of normal, cachectic and diabetic individuals was detd. This shows that the introduction of excess of sugar soln. in the organ from a diabetic organism did not lead to any special formation of lactic acid. The supposition that the diabetic metabolism is such that the sugar decompn. ends with the production of lactic acid must be given up. The evidence seems to point to the fact that the capacity of the muscles to form lactic acid was decreased. (This is not true of the liver.) C. J. Wær.

Clinical calorimetry. VI. Notes on the absorption of fat and protein in typhoid fever. WARREN COLEMAN AND FRANK C. GEPHART. *Arch. Intern. Med.* 15, 882-6(1915).—The feces of 7 typhoid patients on the high calory diet were analyzed for fat and protein in 17 periods of 3 to 12 days each. The av. amt. of fat found was 6.25 g. or 4.3% of that ingested. No differences were observed between the early and the late stages of the fever or up to the first week of convalescence. The av. amt. of N was 1.57 g. or 11.2% of that ingested. VII. Calorimeter observations on the metabolism of typhoid patients with and without food. WARREN COLEMAN AND EUGENE F. DU BOIS. *Ibid* 887-938; cf. C. A. 8, 3679.—The heat production of typhoid patients was measured by direct and indirect calorimetry in 61 expts. There was close agreement, the total divergence being 2.2% and the av. 5%. The respiratory quotients were normal. Therefore, in typhoid fever, protein, fat and carbohydrate are oxidized to the same, or approx. the same, end-products as in health, with the liberation of the standard amt. of heat. The rectal temp. does not give an accurate indication of the av. change in body temp. in these patients. Better results are obtained with surface thermometers. The basal heat production roughly parallels the temp. At the height of the fever it averages about 40% above the normal but it may be more than 50% above the normal. The specific dynamic action of protein and carbohydrate is much smaller in the febrile period of typhoid than in health and in some cases seems to be absent. In convalescence, it may be greater than normal. Typhoid patients can store body-fat on an abundant diet while losing body-weight and body-protein. Loss in wt. and loss in protein are usually, but not necessarily, parallel. There is toxic destruction of protein in typhoid fever, since N is lost on a diet containing more than enough calories to cover the heat production and also a normal amt. of N. VIII. On the dia-

betic respiratory quotient. GRAHAM LUSK. *Ibid* 939-44.—Discussion. Cf. C. A. 9, 1794. I. GREENWALD.

JORDAN, W. H.: *Principles of Human Nutrition*. Reprint, 1914. New York: Macmillan Co. 450 pp. \$1.75.

F. PHYSIOLOGY.

ANDREW HUNTER.

The mechanism of urinary secretion by the kidneys. ERICH LESCHKE. *Z. klin. Med.* 81, 14-35(1914).—Rabbits and guinea pigs were injected with solns. of NaCl, urea, phosphates, uric acid and iodides. The animals were killed and pieces of kidney were treated so that the injected materials were fixed *in situ*, and their distribution detd. In the case of the chloride the fixing was accomplished by immersing in a HNO_3 - AgNO_3 soln., washing in H_2O and treating with photographic developing fluid. The urea was fixed by placing the kidney sample in a HgNO_3 soln., the latter being decomposed with H_2S . The phosphates were fixed by means of U acetate and $\text{Na}_4\text{Fe}(\text{CN})_6$. The purines were fixed by placing in an ammoniacal Ag soln. and subsequently treating with photographic fluid as in the case of the Cl. The specimens were then sectioned. The injected materials were found almost exclusively in the tubules, and only in traces if at all in the glomeruli. M. S. F.

Nuclear digestion and uric acid excretion in a case of total occlusion of the pancreatic duct. DANA W. ARCHLEY. Johns Hopkins Hosp. *Arch. Intern. Med.* 15, 654-8(1915).—A patient with carcinoma of the pancreas, with complete absence of trypsin, lipase and diastase from the duodenal contents and presumably total occlusion of the pancreatic duct, was kept on a purine-free diet for several days and then fed calf thymus. There was a prompt increase in the output of uric acid, as large as that observed by other investigators after feeding the same amt. of thymus to normal individuals. The presence of pancreatic secretion in the intestine is apparently not necessary to the metabolism of ingested nuclear material. I. GREENWALD.

The cholesterol metabolism of the hen egg during incubation. J. H. MUELLER. Columbia Univ. *J. Biol. Chem.* 21, 23-8(1915).—Embryos were analyzed for cholesterol and cholesterol esters at 2-day intervals from the 3rd to the 21st day of incubation. The cholesterol of the newly laid egg is practically all in the free condition and remains so up to the 13th day. After that there is gradual esterification until at the time of hatching over 40% is in the form of esters. The sudden production of esters is apparently connected with the process of calcification, the P necessary for this process being made available by the breaking down of lecithin. The fatty acids thus liberated are in part oxidized or recombined as neutral fats with glycerol and the remainder is combined with cholesterol forming non-toxic esters. The esterifying cholesterol thus functions as a detoxifying substance. A. P. LOTHROP.

Cerebrospinal fluid. VIII. The effect of pituitary extract upon its secretion. L. H. WREED AND HARVEY CUSHING. *Am. J. Physiol.* 36, 77-103(1915).—Expts. on etherized dogs indicate that exts. of the posterior lobe of the hypophysis increase the rate of production of cerebrospinal fluid by stimulating the secretory activity of the choroid plexuses. J. F. LYMAN.

The effect of thyroid extracts upon blood pressure. G. C. FAWCETT, JOHN ROGERS, JESSIE M. RAHE and S. P. BEGBE. *Am. J. Physiol.* 36, 113-25(1915).—From fresh pig thyroids, the following fractions were sepd. and their physiol. action on dogs detd.: (1) nucleoproteins, (2) globulins, (3) coagulable albumins, (4) non-coagulable albumins, (5) alc.-sol. residue, (6) alc.-insol. residue. I, while present in all fractions, was contained largely in the protein preps., which gave no depressor effect on blood pressure. The residue free from coagulable proteins gave a strong depressor effect following its

intravenous injection. The active substance is not pptd. by basic Pb acetate, not altered by heat, nor by passage through a Berkefeld filter. J. F. LYMAN.

The physiology of the stomach. XIX. Reflexes from the intestinal mucosa to the stomach. E. H. BRUNEMIER AND A. J. CARLSON. *Am. J. Physiol.* 36, 191-5 (1915).—Gastric hunger contractions are inhibited by the introduction into the intestine of gastric juice, chyme, acids, alkalies, water, milk, and oil. This inhibition is due partly to chem. and partly to mechanical factors, the chem. stimulation producing the greatest effect. J. F. LYMAN.

Action of acids on bird plasma. JOUAN. AND STAUB. *Compt. rend. soc. biol.* 76, 408-9 (1914).—Bird plasma prepd. according to the method of Delezenne and collected with the precautions previously noted by the authors (*Compt. rend. soc. biol.*, Aug. 8, 1910) is not coagulated at 37° by various agents (colloidal Ca oxalate (Nolf), etc.), but invariably sets to a gel in a few hrs. after addition of an equal vol. of distd. H₂O or small amts. of various acids (H₂SO₄, HCl, AcOH, BzOH, lactic, boric). The amt. of acid which is added should not exceed that which is required to neutralize the normal alkalinity with litmus as indicator. If this amt. of acid is exceeded, a ppt. of fibrinogen sol. in an excess of acid is formed; the flocculent ppt. does not become agglomerated in filaments or a clot. The following explanations of this phenomenon are possible: (1) the liquid condition of the blood is maintained primarily by the alk. reaction of the medium; (2) normal antithrombin is dependent in some manner upon the alkalinity of the blood (hypothesis of Dastre and Floresco regarding the nature of the antithrombin of peptone blood); (3) the acids cause the cleavage of a combination of fibrinogen or perhaps play a thromboplastic role in the sense indicated by Nolf. These possibilities will be investigated. The preceding observations were made independently of those of Piettre and Vila regarding the same subject. H. S. PAINE.

Is the Abderhalden reaction a "mutual" phenomenon in so far as woman and the bitch are concerned? SUZANNE DEJUST. *Compt. rend. soc. biol.* 76, 472-3 (1914).—The serum of a non-pregnant bitch did not give dialyzable products which were detectable by ninhydrin: (a) when it was placed alone in the dialyzer; (b) when it was placed in the dialyzer in the presence of placenta of the bitch; (c) when it was placed in the dialyzer in the presence of human placenta. The serum of a pregnant bitch attacked human placenta in the same manner as did the serum of a pregnant woman; the intensity of the color reaction was the same. The serum of a pregnant woman behaved toward the placenta of the bitch in the same manner as toward human placenta. The serum of a pregnant bitch attacked the placenta of the bitch in the same manner as the serum of a pregnant woman attacked human placenta. A negative result obtained in testing the permeability of dialyzers to egg albumen was not always found to be a sufficient guarantee of impermeability to serum albumin; the permeability of dialyzers to the latter should, therefore, always be tested. H. S. PAINE.

Chemical composition of the globulins. MARCEL AYNAUD. *Compt. rend. soc. biol.* 76, 480-1 (1914).—Globulins obtained as pure as possible from the blood of the horse and ass contained approx. 4% ash (on the dry basis) and the presence of P, Fe, S and Ca in the latter was of const. occurrence; the possibility that the presence of Fe was due to contamination (erythrocytes, etc.) was eliminated by special precautions. The globulins contained a relatively large proportion (about 15% of the dry wt.) of substances sol. in alc., Et₂O and CHCl₃. The alc. ext. yielded on evapn. irregular masses of fatty appearance and rancid odor and which contained no crystals. The alc.-Et₂O ext. contained P; it is, therefore, probable that a portion at least of this ext. was composed of lecithin or lipoids. The relatively high content of substance sol. in fat solvents and the presence of P, taken in connection with the color reactions of the globulins, the insolubility of the latter in gastric juice and their digestion by pancreatic

juice, constitute grounds for the assumption of the presence of nuclear substance in a diffuse state.

H. S. PAINE.

Hypophyso-toxic serum. CH. LÉVON. *Marseilles. Compt. rend. soc. biol.* 76, 512-3 (1914).—Intraperitoneal injection of guinea-pig hypophyses in rabbits in a vehicle of physiol. serum was quickly followed by emission of urine containing glucose. Intraperitoneal injection into young guinea pigs of serum from these rabbits resulted in arrested growth and loss of wt.; many of the animals died, while those which survived finally attained a normal development. No effects on the dead or living guinea pigs were observed which warranted the assumption that the rabbit serum was hypophyso-toxic.

H. GIDEON WELLS.

Agglutination of *Spirochaeta pallida*. A. KISSINGER. *Deut. med. Wochschr.* 41, 306-8 (1915).—Serum of syphilitic patients agglutinates *Spirochaeta pallida* specifically. The reaction is not constant but occurs in all periods of the disease. Intravenous injections of cultures of the spirochaetes in rabbits give a blood rich in agglutinins.

S. AMBERG.

Detoxification of diphtheria and tetanus toxin. J. SCHUMACHER. *Deut. med. Wochschr.* 41, 310-1 (1915).—In test tube expts. as well as with patients, $(\text{NH}_4)_2\text{S}_2\text{O}_8$ proved a good antigonorrheic. Guinea pigs on receiving 8 times fatal dose of diphtheria toxin died in 24 hrs. When the toxin was mixed in the syringe with 2 cc. 5% $(\text{NH}_4)_2\text{S}_2\text{O}_8$ the animals did not show any symptoms. A subcutaneous injection of 2 cc. 5% $(\text{NH}_4)_2\text{S}_2\text{O}_8$ preceding the toxin injection by 10 min. prolonged the life of the animals 12 hrs. Analogous results were obtained with tetanus toxin.

S. AMBERG.

† **The cerebrospinal fluid and the effect of lumbar puncture in delirium potatorum.** R. STEINEBACH. *Deut. med. Wochschr.* 41, 369-72 (1915).—The cerebrospinal fluid of patients with delirium tremens frequently contains alcohol, depending upon the time and amt. of the last dose. The alcohol content of the cerebrospinal fluid does not stand in any relation to the delirium. Lumbar puncture is very valuable in relieving delirium.

S. AMBERG.

The simultaneous use of hemolysins and hemagglutinins as indicators in the complement deviation reaction for the demonstration of syphilis. W. PFLEGER AND G. SCHEYER. *Münch. med. Wochschr.* 62, 393-5 (1915).—The so-called conglutination reaction has proved of value in the diagnosis of glanders. A new method is given which permits its applicability in syphilis. It is a complement-fixation reaction whereby horse serum is used as complement, etc., ox heart cholesterol ext. as antigen, and as hemolytic system cattle serum with 1% guinea pig b. c. suspension. This reaction needs only very small amounts of serum. It is called a conglutination reaction because there is a combined effect of hemagglutination and complement fixation.

† **Dimethylaminobenzaldehyde reaction of Ehrlich in the urine of children with scarlet fever, measles, diphtheria and various mixed infections.** E. RACHMILEWITSCH. *Jahrb. Kinderheilk.* 81, 168-72 (1915).—300 cases were examd.

M. S. F.

Significance of noncoagulable nitrogen coefficient of blood serum in pregnancy and toxemias of pregnancy. R. D. PLASS. Baltimore. *Am. J. Obst. and Dis. Women and Children* 77, No. 4(1915); *J. Am. Med. Assoc.* 64, 1526.—P. claims that the non-coagulable N coeff. is a better index of kidney function than the total non-coagulable N alone. L. W. RIGGS.

The role of tuberculin in antituberculous vaccination. A. JOURNET. *Bull. acad. de méd.* No. 22(1914); *Schweiz. Arch. Ztg.* 53, 137(1915).—The active principle of tuberculosis, whether of human or bovine, avian, or equine type, is characterized by its dialyzing qualities and its thermostability. It is completely pptd. by EtOH and accompanies the lowest products in the degradation scale of the culture bouillon, the amino acids. Biologically, it appears spontaneously between the 2nd and 3rd week, its formation running parallel with the progress of the bacterial films, rapidly reaching a max. The mechanism of this activation is about as follows: From the bacterial cultures, small amts. of nucleocalbumins are sepd. which are the initial tuberculin substance. They are almost devoid of physiological activity. But upon hydrolysis in slightly alk. soln., they acquire by far-going decomp. all specific properties of tuberculin. S. WALDBOTT.

Influence of shaking, ultraviolet rays, and Röntgen rays, upon the complement and the hemolytic amboceptor. VITTORIO SCAFFIDI. Univ. Naples. *Biochem. Z.* 69, 162-80(1915).—Shaking exerts an injurious effect upon the complementary capacity of the serum. This action is the more pronounced when the temp. is high; temp. is without doubt an important factor in the phenomenon. The hemolytic amboceptor is not modified in any way by shaking, even if continued for 3 days at 37°, while the complement is completely inactivated after a few hrs. The ultraviolet rays inactivate both the complement and the hemolytic amboceptor in the same time, provided the amboceptor is used in a diln. 10 times as great as that of the complement. X-rays do not modify either the complement or the amboceptor. The different action of the 2 rays may be explained by assuming that the ultraviolet rays are absorbed by the proteins while the X-rays easily penetrate these substances; the ultraviolet rays, through their energy transformations, induce permanent changes in the vital and biological properties of the living protein. C. J. WEST.

FISCHER, M. H.: *Oedema and Nephritis. A Critical, Experimental, and Clinical Study of the Physiology and Pathology of Water Absorption in the Living Organism.* 2nd ed. New York: John Wiley & Sons. 695 pp. \$5.00.

Acute intoxication due to benzene vapors. A. HEFFMAN. *Deut. med. Wochschr.* 41, 182-5(1915).—A "Gutachten" given by H. concerning a death due to inhalation of vapor of crude benzene. S. AMBERG.

The treatment of syphilis with copper-salvarsan. T. FABRY AND J. SELIG. *Münch. med. Wochschr.* 62, 147-9(1915).—Copper-salvarsan labeled "Cu 3" was obtained from Ehrlich. It contains about 24% As and 11.6% Cu. Salvarsan contains about 34% As, neosalvarsan about 20%. The "Cu 3" does not dissolve readily. The prep. was tolerated very well, but did not seem to act as well as salvarsan. S. AMBERG.

Treatment of lupus by intravenous injection of copper-salvarsan. *Münch. med. Wochschr.* 62, 149-50(1915).—The treatment was without effect. S. AMBERG.

The toxicity of uric and thymic acids in the frog. G. G. COSENTINO. Univ. Rome. *Arch. farm. sper.* 19, 193-202(1915).—Thymic acid, in the frog, whether administered in small, medium, or large doses, is more toxic than equal doses of uric

acid. Simultaneous injection of the two acids is more harmful than an equal dose of either acid separately.

A. W. DOX.

Hematological researches on some cases of acute poisoning by corrosive sublimate. GIOVANNI DONZELLO. Palermo. *Arch. farm. sper.* 19, 203-14(1915).—In all cases of poisoning by HgCl_2 , hyperleucocytosis was observed; this varied in intensity with the amount of the poison introduced into the organism. The red corpuscles undergo no change, numerical or morphological, irrespective of the amount of HgCl_2 assimilated.

A. W. DOX.

Observations on camphorate of quinine and pyramidone. GIULIO NARDELLI. Univ. Rome. *Arch. farm. sper.* 19, 215-20(1915).—This double salt is a splendid antithermic and has the advantage of being without sudorific properties.

A. W. D.

The elimination of iodide in the urine of children. ROBERT AMSTAD. *Jahrb. Kinderheilk.* 81, 222-33(1915).—The elimination starts a few minutes after ingestion and continues for about 36 hrs., about 80% of the whole output appearing in the first 12 hrs. With a dose of 0.1 g. KI in infants, 63.8 to 72.2% was recovered in the urine; with a dose of 0.2 g. KI in children of 3-5 yrs., 37.0 to 49.8% was recovered, and in children of 5-10 yrs., 41.3 to 48% was recovered. In adults, 66.5 to 71% of the ingested iodide reappeared in the urine.

M. S. F.

The influence of temperature and concentration on the quantitative reaction of the heart to ouabain. T. SOLLMANN, W. L. MENDENHALL AND J. L. STINGEL. Western Reserve Univ. *J. Pharmacol.* 6, 533-60(1915).—The toxicity of ouabain for intact frogs, detd. by the 1-hr. systolic arrest dose, increases markedly with the temp., the increase per degree of temp. being much greater at the lower than at the higher temps. The differences are so marked that they cannot be neglected in frog-assay. The M. S. D. for ordinary temps. may be read directly from a curve constructed by the authors. Excized frog hearts show a similar effect of temp. on the activity of ouabain. The temp. activity curves have approx. the same form, for all concs., as the temp. activity curve for intact frogs. The temp. quotients for ouabain activity vary in the direction of van't Hoff's law as applied to biologic phenomena; but quantitatively they correspond more nearly to the square of the ordinary chem. temp. quotients, and to the square of the temp. quotients for the rate of the normal heart. This is explainable by the fact that the activity of ouabain is increased by the temp. not only directly, but also through the increase of heart rate. The temp. quotients are parallel for all concs., but the quotient for a given range of temp. diminishes the higher the conc. The quotients computed for strophanthin and antiarin from a set of Trendelenburg's data vary in the same direction, although they are generally smaller. The concn. coeff., increase of activity/increase of concn., ranges from 1.28 to 4.6, av. 2.5. The feebleness of the action of ouabain, the more is the activity increased by doubling the concn. This is true whether the feeble ouabain action is secured by low conc. or by low temps. At least 4 factors would be concerned in this: The "limit of response," the "inactive dose," "injury by exposure," and "penetration" of the ouabain.

P. J. HANZLIK.

The toxicity of rattlesnake serum and bile, with a note on the effect of bile on the toxicity of venom. WILLIAM H. WELKER AND JOHN MARSHALL. Univ. Penna. *J. Pharmacol.* 6, 563-8(1915).—The intramuscular injection of rattlesnake venom into the same or another snake produced no toxic effects. Serum of rattlesnake injected intraperitoneally into guinea pigs, and intramuscularly into pigeons, appeared to be less toxic than rabbit serum. Captivity of rattlesnake appears to increase the coagulation of blood. Rattlesnake bile possesses low toxicity for pigeons and has no anti-toxic action for rattlesnake venom (contrary to statement of Fraser (*Brit. Med. J.* 2, 125 (1897))).

P. J. H.

Demonstration by the use of arterial rings of the inhibitory action of certain drugs on the vaso-constriction produced by epinephrine. DAVID I. MACHT. Johns Hopkins Univ. *J. Pharmacol.* 6, 591-4(1915).—If an intact animal is previously treated with ergotoxin, an injection of epinephrine produces a fall in blood pressure (Dale's vaso-motor paradox), the pressor effect of epinephrine no longer being obtainable owing to paralysis of the vasoconstrictors. The same phenomenon can be demonstrated with an excized pig carotid artery *in vitro* by immersing it first into Locke soln. containing ergotoxin followed by immersion in Locke soln. containing epinephrine. The simplicity of the expt. with all the essential elements involved present should make it preferable to expts. on the intact animal. The paradoxical effect of epinephrine occurs also with apocodeine, aconitine and nicotine.

P. J. H.

Some vasomotor reactions of the liver. CHAS. W. EDMUNDS. Univ. Mich. *J. Pharmacol.* 6, 569-90(1915).—Injection of epinephrine in the dog usually produces diminution in vol. of the liver; this continues while the blood pressure is reaching its maximum and then returns to normal again. In the cat an increase in vol. is produced usually, and this depends upon the increased cardiac efficiency. Ligation of the hepatic artery with injection of epinephrine results in no marked change in vol. of the liver at first, but later there is a marked increase due to backing of the blood in the vena cava, and it is therefore entirely passive. These changes are not proof of the pressure of vasomotor nerves in the portal vein. However, perfusion of the excized organ with epinephrine reduces the perfusion flow, and treatment of the excized vessels with epinephrine produces constriction. These phenomena, coupled with the fact that an increase of liver vol. with rise in portal pressure in the intact organ follows stimulation of the splanchnics, is considered proof positive that active vasomotors are present in the portal veins.

P. J. H.

The use of "pellidol." KOTTMAIER. *Berl. klin. Wochschr.* 52, 243-4(1915).—"Pellidol" is diacetylaminoozotoluene. It is sol. in oil and fats and has the same stimulating effect on epithelium as aminoazotoluene and scarlet red, but is not so toxic.

JULIAN H. LEWIS.

The action of synthetic camphor. CARL LUTZ. *Berl. klin. Wochschr.* 52, 322-3 (1915).—No harmful action was observed with the use of artificial camphor, and its action on the heart is the same as that of the natural drug.

JULIAN H. LEWIS.

The influence of oxalates, citrates and tartrates on the isolated heart. WILLIAM SALANT AND SELIG HECHT. *Am. J. Physiol.* 36, 126-44(1915).—The toxicity of equimol. solns. of Na salts in the perfused dog heart increases thus: tartrate, oxalate, citrate, and hence cannot be due to pptn. of Ca ions since toxicity does not follow the solubility of the Ca salts. Nor is toxicity due to the formation of nonionized Ca compds. since Ca citrate and tartrate were as well utilized in perfusion expts. as was CaCl₂. It is suggested that the effects are due to extra-cellular changes, possibly to the loss of lipoids or to physico-chem. changes at the surface of the cell.

J. F. LYMAN.

Action of intravenous infusions of sodium chloride, acids and alkalies upon the respiratory metabolism during urethan narcosis. J. C. RAEDER. Univ. Copenhagen. *Biochem. Z.* 69, 257-88(1915).—Urethan narcosis, rightly carried out, makes rabbits suitable for respiration expts. for 2-3 days. The metabolism is quite const., varying about 2% during the course of 1-2 hrs. The kidney secretion is not affected by urethan narcosis. Sudden intravenous injection of physiol. NaCl soln. may cause an increase in the respiratory metabolism. In investigating the action of different solns. upon the respiratory metabolism one can avoid the sudden action upon metabolism by a permanent infusion of physiol. NaCl soln. before the infusion of the soln. to be tested. The work of the heart and kidneys is const. Infusions of NaCl solns. cause increase of the respiratory metabolism. With stronger concns., metabolism sinks, probably because

of poisonous action upon the cells and a high osmotic pressure. As a rule the increased metabolism is accompanied by increased urine secretion. All the NaCl appears a few hrs. after the injection, being retained only in the case of coned. soins. Perhaps the increased metabolism depends upon this NaCl excretion and the increased excretion of fluid. Na_2CO_3 increases the O-consumption. Acids also appear to increase the O consumption, yet the respiratory metabolism soon decreases (poisoning). Concns. of 0.2 N NaOH and 0.166 N HCl cannot be used for intravenous injection.

C. J. WEST.

Urotropine as a disinfectant of the urinary passage. H. F. HÖRST. *Z. Min. Med.* 81, 272-84(1915).—The decompn. of urotropine under various conditions of temp., acidity and alkalinity is considered.

M. S. F.

Soluble aluminium compounds. Their occurrence in certain vegetable products. C. N. MEYERS AND C. VORGMAN. *Publ. Health Reports* 29, 1625-9(1914).—By means of feeding expts. on small animals the presence of a sol. toxic substance in corn, sweet potatoes and other vegetable products was shown. Sol. Al compds. were found in a considerable quantity in the same products. Results are only preliminary but suggest a possible connection between Al in food products and pellagra.

I. ZOOLOGY.

R. A. GORTNER.

Fat content and the biological significance of the same for the fish and its habitat; fat content depending upon the age of the fish. OSW. POLIMANTI. Naples. *Biochem. Z.* 69, 145-54(1915); cf. *C. A.* 8, 1170.—The earlier conclusion, that surface swimming fish have the highest fat content, is confirmed. Animals which change their habitat during growth show a similar change in fat and H_2O content. Thus an animal that lives on the surface while young and upon reaching maturity lives 6 to 12 m. from the surface will show a decreased H_2O and an increased fat content. C. J. WEST.

The fats in the liver of the Selachii (*Amyliobatis aquila*). ARFFAERLE PALADINO. Univ. Naples. *Biochem. Z.* 69, 192-8(1915).—The fat shows the following physical constants: d. 0.9245, m. 50° , solidifies at 20° . It shows 2 absorption bands, one in the red near C and the other in the yellow near D. The acid no. is 10.2, sapon. no. 193.8, R.-M. no. 2.66, I no. 104.8. The presence of oleic, palmitic and stearic acids was shown. It contains P and Fe.

C. J. WEST.

12. FOODS.

W. D. BIGELOW.

The velocity of staling of bread. J. R. KATZ. Univ. Amsterdam. *Verslag. Akad. Wetenschappen* 23, 652-5(1914).—In a former communication K. pointed out that the staling of bread depends on a change in the starch of the flour such that it becomes harder and less capable of holding water. (Cf. *C. A.* 7, 3169; 8, 184.) K. now finds that the staling of the bread and its loss of imbibing power do not run quite parallel, the latter taking place more rapidly. Mention is made of the fact that the vapor pressure of both fresh and stale bread is not noticeably different from that of pure water.

L. H. ADAMS.

The staling of bread is connected with a change which takes place not only with wheat and rye starch but also with all varieties of starch, but it leads to practically important results only in the case of wheat and rye starch. J. R. KATZ. *Verslag. Akad. Wetenschappen* 23, 655-8(1914); cf. preceding abstr.—An account of expts. on the imbibing power and solubility of "bread" made of flour or meal from 8 different kinds of grain.

L. H. ADAMS.

Revised method for the determination of crude fiber in flour. K. BAUER. *Z. ges. Getreidew.* 5, 295(1913); *Chem. Tech. Rept.* 38, 341.—The amt. of sample needed for analysis varies with the kind of flour under exam. Of light colored grades 3 g., of dark colored 2 g., and of bran 1 g. should be taken. Introduce the sample into 200 cc. of 1.25% H_2SO_4 and boil for 30 min. In the case of bran, the boiling should last 1 hr. Agitate frequently during boiling. Boiling on an asbestos plate is recommended. After cooling add 15 cc. 30% KOH; this causes the albuminous matter to dissolve. The entire mixt. is now filtered through asbestos and the residue treated in the usual manner. The fiber obtained in this way is free from pentosans and protein, but contains largely lignin, suberin and a pigment.

SIMON MENDELSSOHN.

The microscopical examination of flour and pastry preparations, especially concerning the detection of potato constituents. F. BENGEN. *Stettin. Z. Nahr.-Genussm.* 29, 247-51(1915).—When the potato starch has not entirely lost its outlines treat about 2 cc. of a suspension of the substance with 2-3 drops of Löffler's methylene blue soln., shake, and centrifuge for a very short time, sufficient to bring the least broken down of the starch grains to the bottom of the container. Decant the liquid and wash the residue once by centrifuging and decanting. Potato starch is stained blue whereas the cereal starch remains unchanged. When a potato prepn. in which the starch grains have been entirely disintegrated has been used, rub a piece as big as a walnut with about 30 cc. of water, allow to settle for a short time, decant the liquid, add 25 cc. of 15% NaOH to the residue, stir till a thick jelly forms, add Br-water a little at a time with stirring until the mixt. again becomes limpid, centrifuge and exam. the residue under the microscope, potato being indicated by the characteristic tissue (cork cells, spiral and reticulated vessels, giant cells, and numerous parenchyma cells, the contents of which become stained with methylene blue). When thoroughly cooked peeled potatoes have been used, the microscopical characters are the same as in the last case except that cork cells are absent and the contents of the parenchyma cells do not become stained with methylene blue. Even in cases when potato starch grains are greatly distorted by cooking they often still retain to a considerable degree their peculiarities under polarized light. Some forms of potato starch are imperfectly or not at all stained by methylene blue.

A. F. SEEKER.

Color analysis of bread. C. POSNER. *Berl. klin. Wochschr.* 52, 173-7(1915).—Each variety of meal, when colored with Giemsa's stain, has a characteristic appearance under the microscope, even when it is made into bread. P. advocates this procedure to det. the kind of meal and bread and their purity.

JULIAN H. LEWIS.

A new staining process for potato starch. G. BLUNCK. *Mirow. Z. Nahr.-Genussm.* 29, 246-7(1915).—After trying a large number of stains in an attempt to find a selective one for potato starch in order to detect the presence of the latter in flour and bread, B. found that Metachrom Red G (Agfa Co.) answered the purpose. Sat. boiling 30% EtOH with the dye, cool, filter and dil. with 25% of water. Suspend a little of the substance to be examd. in a drop of water upon a microscope slide, dry, moisten with a drop of the dye soln., wash quickly with water, and dry again. Potato starch as well as cell tissues are stained an intense golden yellow but cereal starches remain unaffected. The sample must be perfectly neutral in reaction to render the test successful.

A. F. SEEKER.

Review of work in chemistry of milk and dairying in 1913. GRIMMER. *Milch-wirtsch. Zentr.* 43, 482-6, 497-503, 513-7(1914).

L. L. VAN SLYKE.

Alizarol test of milk. W. D. KOOPHA. *Milchwirtsch. Zentr.* 43, 487-93(1914). A discussion.

L. L. VAN SLYKE.

Comparative tests of several methods for cheese fat determination with special reference to a modified extraction process. N. A. BRODRICK-PITTARD. *Liebfeld-*

Bern. *Z. Nahr.-Genussm.*, 29, 112-7(1915).—The Ratzlaff method yields too low results owing to the use of ether-petroleum ether as a solvent; it fails to ext. cholesterol, a legitimate fat constituent. Eight detns. showed that in cheese containing from 13 to 37% fat, results were about 0.5% lower than when ether alone was used as a solvent. The Schmid-Bondzynski method also yields low results (from 0.12 to 0.39%) owing to the retention of some of the ether soln. of the fat by the acid aqueous layer. If 2 extns. with ether are made and all except 1-2 cc. of the ether layer removed each time satisfactory results are obtained. The Gerber van Gulik method gives results which may be as much as 1% too high. B.-P. recommends the extn. method of Allemann who employs a special glass vessel, cylindrical in shape, which fits within a Soxhlet extractor. Weigh 1 to 5 g. of cheese into this vessel, add 20 cc. of 20 to 25% HCl, heat on a steam bath until the cheese is dissolved, cool, place a thistle tube in the vessel so that the end of the stem reaches the bottom, fit the whole into a Soxhlet extractor and ext. with ether for 3 hrs. Evap. the ether from the ext. and weigh the fat. Exptl. results were excellent.

A. F. SEEKER.

Significance of *Bacillus coli* in pasteurized milk. L. P. SHIPPEN. Baltimore. *J. Am. Med. Assoc.* 64, 1289-91(1915).—Certain strains of *B. coli* are not killed by a temp. exceeding that commonly used in pasteurization. The thermal death point of this and similar organisms is not a constant quantity but varies for different strains of the same bacterium. In the case of *B. coli communior* this variation was found to be as great as 13°. The presence of *B. coli* in pasteurized milk cannot be taken as an index of its improper pasteurization or subsequent contamination. L. W. RIGGS.

Studies relating to the Roquefort and Camembert type of cheese. CHARLES THOM, J. N. CURRIE AND K. J. MATHESON. Conn. Storrs Agr. Exp. Station, *Bull.* 79, 387-94(1914).—In the mold-ripened cheeses salt is applied after 1 or more days of drainage. It does not, therefore, affect the initial souring which is the 1st step in ripening all these varieties. Its effect upon ripening agents may be estd. by calculating the strength of the brine formed by the soln. of the percentage of salt found in the percentage of water present. The percentage of salt which may be incorporated into a variety of cheese is directly limited by the intensity of the flavors to be developed. In the hard cheeses with their mild flavors, more than 1-1.5% salt becomes offensive. In Camembert 2.5% is acceptable, and in Roquefort, 4%. As a factor in cheese biology, salt restrains the development of *Oidium* in Camembert and prevents it in Roquefort. Salt delays but does not prevent the development of the molds active in ripening Camembert, Roquefort, and the ripened forms of Neufchatel. 10% of salt in culture media stopped or reduced to a negligible quantity the growth of *Penicillium pinophilum*, *P. lilacinum*, *P. luteum*, *P. digitalum*, *P. purpurogenum*, *P. roseum*, *P. duclauxi*, *Aspergillus nidulans*, *A. fumigatus* and *Oidium (Oospora) lactis*. The rate of development of the other species tried was markedly retarded, but more or less characteristic colonies finally developed.

B. E. BROWN.

A synthetic medium for the determination of colon bacilli in ice cream. S. H. AYERS AND W. T. JOHNSON, JR. *Science* 39, 802-3(1914).—A method for the determination of colon bacilli in ice cream is given. The culture medium is agar 1.5%, asparagine 0.3%, NaH_2PO_4 0.1%, lactose 1%, satd. soln. of litmus 2%. Most bacteria do not grow in this medium, while the colon colonies are readily found by reason of their acidity.

WM. P. GARRETY.

Composition of frozen meat. ARIGHT. *L'industria lattiera e zootecnica* 1913; *Boll. chim. farm.* 53, 430(1914).—A. analyzed portions of lamb and ram flesh which had been kept for 160 days at -17° and -7°. The modifications observed in the comp. of this meat were of little consequence. The proportion of sol. substances was much greater in putrefied meat. Freezing caused the meat to lose 2-3% of H_2O ; the amt.

of peptones was increased and the content of coagulable N was decreased. The degree of acidity and the nutritive value of the meat were not affected. H. S. PAINE.

The Fiehe reaction in mixed honeys. O. LÜNING. Braunschweig. *Z. Nahr.-Genussm.* 29, 117-20(1915).—A suspected case of adulteration was investigated and found to be caused by the methods employed by the packer in heating the honey previous to blending. The honey (Cuban and Haitian) was liquefied by heating for $\frac{1}{2}$ to 4 hrs. at about 65 to 90°, strained through a screen and mixed in a blending tank in which over 24 hrs. was required before a normal temp. was regained. A bbl. of honey which before the initial heating gave a negative test was found after this process to give a slightly positive Fiehe reaction. Eight other bbls. were found to give negative tests even after heating. These results were explained by the fact that the honey in the first bbl. had a higher acidity (2.2 mg. equivalents per 100 g.) than the others (1.1 to 1.3 mg.). The diastase test in all cases both before and after heating was positive. L. points out the possibility that suspicious reactions in other cases are due to a like practice on the part of other packers. A. F. SEEKER.

Comment on the work of Sprinkmeyer and Diedrichs. "The determination of vegetable fats in animal fats." E. SALKOWSKI. Berlin. *Z. Nahr.-Genussm.* 29, 49-50(1915); cf. C. A. 9, 940.—Controversial. H. L. LOURIE.

Investigations on fatty fruits and seeds of our (German) colonies. IV. *Canarium polyphyllum*. H. WAGNER AND B. LAMPART. Duisberg. *Z. Nahr.-Genussm.* 29, 105-11(1915).—The nuts of the tree *Canarium polyphyllum* (Burseraceae) (plentiful on the island of New Guinea) are extensively eaten by the natives and produce a com. oil called "Java almond oil." Analysis of the kernels showed 4.87% moisture, ash 3.51 (of which the P_2O_5 was 1.16%), fat 69.58, N 2.23, crude fiber 0.84, and N-free ext. 7.46%. The fat gave negative Halphen and hexabromide tests and both the Bellier and Baudoin reactions gave faint violet colorations. Further analysis gave: $d_{40} 0.9042$, refract. reading (40°) 47.4, m. p. 22.0°, solidifying p. 9-10°, acid no. 1.49, sapon. no. 189.7, I no. (Hübl) 52.95, R.-M. no. 0.33, Polenske no. 0.40. The mixed acids showed: m. p. 45.0°, solidifying p. 38.0-37.5°, neutralization value 200.9, mean mol. wt. 279.2, I no. 59.41, refract. reading (49.5°) 27.4, and contained 48.54% stearic acid. The liquid fatty acids had an I no. of 103.3 and a refract. reading (40°) 41.4. The solid fatty acids had a m. p. between 57.5 and 58° and a solidifying p. of 52.0 to 51.5°, neutralization value 209.7, mean mol. wt. 267.5, the pure Pb salt m. 110.5° and solidifying at 106.0°. No evidence of myristic acid could be found in the acids prepared from the alc.-sol. Li salts of the mixed fatty acids. The fat contained 0.1492% of phytosterol and the m. p. of the solid glycerides was 11.0° higher than that of their fatty acids (Bömer method). Reference is made to the work of others upon this nut and upon the nuts of 2 other *Canarium* species, *C. oleosum* (Lam.) and *C. commune* (L.) (pili nut) both of which resemble the *C. polyphyllum* nut very closely. These nuts all have a high food value and the press cake makes an excellent feed for cattle. A. F. S.

Glass apples. G. PARIS. *Stas. sper. agrar. ital.* 47, 702-32(1914); *Chem. Zentr.* 1915, I, 493-4.—Apples whose pulp is entirely or partly transparent are called glass apples. Numerous varieties are represented and described. Tables contg. the results of analyses of sound and glassy apples hardly show a difference. In the glassy ones, the dried material is somewhat lower and richer in cellulose, pectin materials, and fats, while on the other hand, it is slightly poorer in sugars, pentosans, S and protein compds. The vitrification cannot be attributed to bacterial action or diastatic changes, but is due rather to other influences, above all lack of air, produced by a diseased condition of the sarcocarp which is rendered impermeable to air. This is proved by artificial cpts. (coating with paraffin) and also by photomicrographs. C. F. MILLER.

Some varieties of olives of Umbria. G. B. GIAMMARONI-CHERUBINI. *Stas. sper. agrar. ital.* 47, 575-602 (1914).—G.-C. gives descriptions of the tree, leaf, olive, and stone, and data of the moisture and crude fat content of the pulp. In some cases the yield of oil is given. L. J. GILLESPIE.

Studies on the factors affecting the culinary quality of potatoes. O. R. BURLING, F. B. MORRISON AND F. E. BOLL. *J. Am. Soc. Agronomy* 5, 1-33 (1913).—Mealiness is modified by the water content, potatoes high in water being less mealy than those relatively low in water. The % of starch in a potato is not indicative of mealiness. The ratio of Condon and Bussard, albuminoid N/starch, does not appear to be a very reliable indicator of the degree of mealiness of potatoes. The presence of sugar in a potato is detrimental to its quality. The %, however, that may be tolerated varies with diff. varieties. The ratio total N/starch is no criterion of quality. B. E. BROWN.

Coconut meal. J. B. LINDSEY. Mass. Agr. Expt. Sta., *Bull.* 155, 182-90 (1914).—Expts. were conducted to det. the digestibility and food value of coconut meal. It is equal in nutritive value to gluten feed, and in moderate amts. is favorable to the production of firm-textured butter. B. E. BROWN.

The effect of pressure on certain microorganisms encountered in preserving fruits and vegetables. B. H. HITE, N. J. GIDDINGS AND C. E. WEAKLEY, JR. West Va. Expt. Sta., *Bull.* 146 (1914).—Grape and apple juice were effectively sterilized by high pressures (30,000 to 80,000 lbs.) applied from 30 min. to 16 hrs. Tomatoes spoiled after pressure treatment, but more slowly than without the treatment. The problems studied were: "Whether or not a certain organism could be killed by such pressures as we could safely and easily apply; the time pressure death point curve, that is the relation between amt. of pressure and length of time it is applied; the effect of high and low temps. on death point curve; the effect of reaction of the media on death point curve." Technic and app. are described in detail. WM. P. GARRETT.

Love gifts upon the (German) food market. A. JUCKENACK. Berlin. *Z. Nahr.-Genussm.* 29, 241-6 (1915).—Many new forms of gifts in the way of foods have appeared upon the German market to meet the demands of those wishing to send tokens of affection to soldiers in the field. Among them are so-called rum or grog cubes containing alc. and made in the form of a jelly by means of gelatin, so-called alc.-free exts. consisting of various flavoring substances, sugar and coal tar colors, compressed cubes and tablets of coffee, tea and cocoa, and milk tablets. A number of these have been examd. and found to be frauds. A. F. SEEKER.

Testing apparatus used in the manufacture of carbonated beverages. KARL ALPERS. Univ. Tübingen. *Pharm. Ztg.* 60, 204-6 (1915).—The investigation carried out from a hygienic standpoint involved the detection of Cu, Zn and Pb not only in the beverages themselves after standing 12 hrs. but also in the solder and lining of the containers. In view of the strict application of the police regulations, the opinion is expressed that it might be well to substitute Ag for Sn as a lining material. W. O. E.

Ger., 280,999, Jan. 10, 1913. H. KERSKEN and E. BODSTEIN. Mfg. a comp. for preventing boiler scale. The compns. used heretofore, containing fatty constituents, have proved unsatisfactory because of failure to adhere to the surfaces of the boiler or tubes. In this process an emulsion of mineral, animal, or vegetable oils, without the use of alkalis, is made so complete that the walls remain coated permanently with a layer of fat. Furthermore, the product has a direct solvent action upon the scale already present. See C. A. 8, 2440.

15. SOILS AND FERTILIZERS.

M. X. SULLIVAN.

Thomas Kosutiny. FRITZ V. KONEK-NORWALL. *Chem. Ztg.* 39, 105(1915).—An obituary. J. H. MOORE.

The engineering properties of soils. R. O. E. DAVIS. *J. Ind. Eng. Chem.* 7, 422-5(1915).—The engineering properties of the soil, *e. g.*, rigidity, cohesiveness, penetrability and porosity, are influenced by mechanical compn., mineralogical compn. and moisture content. The moisture relations have been studied and results are shown by curves. ISADOR MILLER.

Lithium in soils. L. A. STEINKOENIG. *J. Ind. Eng. Chem.* 7, 425-6(1915).—S. reviews the occurrences of Li in various substances as mentioned in the literature (references given) and gives a table showing the amt. of Li found in a number of soils collected from 6 different areas. All contained Li in small amts. ISADOR MILLER.

Effect on soil moisture of changes in the surface tension of the soil solution brought about by the addition of soluble salts. P. E. KARRAKER. *J. Agr. Res.* 4, 187-92 (1915).—The results from the expts. indicate that changes in the surface tension of the soil soln. arising from the application of fertilizing salts are of no importance in affecting the moisture condition of the soil. M. X. S.

Colloidal properties of acid soils of Japan. II. T. TAKODORO. *J. Coll. Agr., Tokoku Imp. Univ.* 6, 117-29(1914); cf. *C. A.* 9, 231.—The colloidal properties of 3 neutral soils, a sandy soil, a clay, and a humus soil, and 2 mineral acid soils of Japan are compared. The degree of swelling (increased vol.), detd. in alc., water, Na phosphate, Na tartrate, Na_2CO_3 , NaOH, HCl, and acetic acid, was greatest in NaOH and Na_2CO_3 and lowest in alc. The degree of swelling is greater for the mineral acid soils than for the neutral soils, especially in NaOH and Na_2CO_3 . The order of the degree of swelling for the different soils is: mineral acid soils > humus soil > clay soil > sandy soil. There is no relation between the absorbing power for NH_3 and that for dyes or the degree of swelling or the hygroscopic power in the different soils. The NH_3 absorption coeff. of soils from $(\text{NH}_4)_2\text{HPO}_4$ soln. is greater than that from NH_4Cl soln. This coeff. is usually greater in the acid soils than in the neutral soils. In the case of the neutral soils it is highest in the humus soil and lowest in the sandy soil. The absorbing power for dyes is greatest in the humus soil and lowest in the sandy soil. The absorbing power of the mineral acid soils for dyes is much less than in the neutral soils. For the neutral soils the hygroscopic power is in the order: clay soil > humus soil > sandy soil. There is no relation between the hygroscopic power of the acid soils and the neutral soils. The results are variable. E. H. WALTERS.

The fixation of nitrogen in Colorado soils. The distribution of the nitrates and their relation to the alkalis. WM. P. HEADDEN. Colorado Agr. Expt. Sta., *Bull.* 186, 47 pp. (1913).—"The distribution of the nitrates in our soils cannot be consistently accounted for by any theory of concn. of preëxisting nitrates. Their distribution is wholly independent of that of the alkalis, the latter being practically free from nitrates, while the aq. ext. of our soils, especially those showing the brown color due to *Asotobacter*, are extremely rich in Ca and Mg nitrates." It is pointed out that the shales and sandstones do not furnish the nitrates, as the well waters are not richer in nitrates than is usual; and, furthermore, that so-called "nitre spots" occur in localities where the shales and sandstones do not occur. The nitrate alone could not produce the brown color of these spots. *Asotobacter* in the presence of nitrates produce a dark brown color. It is therefore claimed that the accumulation of nitrate is due to bacterial agencies.

B. E. B.

The action of foliage and needle forests upon the soil and the plants growing on it. A. KOCH. *Centr. Bakt. Parasitenk., Abt. II* 41, 18-23(1914); *Bied. Zentr.* 44, 87-9. —Buckwheat grown in pot cultures of beech humus gave nearly twice as great a yield as that grown in humus from a pine forest. Both beechnuts and pine seed thrived in beech humus, whereas both developed imperfectly in the pine humus and finally died. To det. the cause for the poor vegetative condition of the pine humus, K. observed the effect of various substances obtained from pines either directly or as a result of decompn., on seeds, seedlings, yeasts, and bacteria. Among the substances used were turpentine, carvene, bornyl esters, silver fir oil, tannin, HCO_2H and rosin. Turpentine, carvene, silver fir oil and HCO_2H had a toxic action on dwarf corn seedlings while tannin and rosin did not appear to have any influence on them. Turpentine and carvene were not toxic to wheat, rye, buckwheat, peas, rape, or cauliflower seeds, and old, normal plants sprinkled with varying amts. of turpentine, carvene, and fir oil were only injured slightly. A marked difference was found in the behavior of cress and rape towards the vapors of the substances used. Cress was killed more quickly by turpentine than by carvene while, on the other hand, rape was killed by carvene, but revived after treatment with turpentine vapors. All of the substances inhibited the fermentation of yeast and some prevented its reproduction as well. Bornyl esters and carvene were strongly toxic to the growth of soil bacteria, 10% turpentine only slightly so, while 1% turpentine exerted a stimulating effect. All of the substances with the exception of HCO_2H also lessened nitrification in the soil. $(\text{NH}_4)_2\text{SO}_4$ was perceptibly nitrified in the beech humus but no reaction took place in the pine humus. The investigation showed that the toxic action of the decompn. products of pines is at least partly responsible for the poor vegetative condition existing in pine forests.

C. F. MILLER.

The alkaline reaction of soils provoked by acids in relation to the nutrition of plants. I. Making iron compounds in the soil soluble. GIULIO MABONI. *Stas. sper. agrar. ital.* 47, 674-701(1914); through *Chem. Zentr.* 1915, I, 498.—Continuation of earlier work (cf. C. A. 7, 3381) with special reference to lime soils contg. Fe. The investigation explains chlorosis in such soils as a consequence of the sepn. of insol. Fe compds. through the alk. soil solns. which are formed.

L. J. GILLERPIE.

Relations between total phosphoric acid and that soluble in "water and citrate" in some soils of middle Peru. A. HUTIN. *Ann. chim. anal.* 20, 31(1915).—Analyses are reported of 6 soils and their subsoils for total P_2O_5 and P_2O_5 sol. in water and citrate (method of Dyer). The figures show total P_2O_5 higher in the soil than in the subsoil, though the ratio of sol. to total is more nearly the same for both. In most cases 39-53% of the total was sol.

L. J. GILLERPIE.

Changes of sulfur and sulfur compounds in soils. H. KAPPEN AND E. QUENSELL. *Landw. Versuchs-stat.* 86, 1-34(1915); *J. Chem. Soc.* 108, II, 203.—When moist soil is treated with H_2S , the soil is blackened owing to the production of FeS , and a portion of the sulfide then undergoes a process of oxidation, in which all of the S is liberated, so that the whole of the H_2S absorbed is converted into free S. The S is then oxidized to H_2SO_4 , the change being more rapid in normal than in sterilized soils. It is, however, doubtful whether the slower oxidation of S in sterilized soils is due to the sterilizing process. Sulfides and sulfites are decomposed more quickly in presence of soil than without soil. In soils the decompn. is so rapid that no injurious effects on germination and growth are to be expected.

E. H. WALTERS.

The effect of fertilizers on the physical properties of Hawaiian soils. WILLIAM McGEORGE. Hawaii Agr. Expt. Sta., *Bull.* 38, 31 pp.(1915).—Results are given of expts. made to det. the effect of various fertilizers upon capillarity, percolation, flocculation, cohesion, apparent sp. gr., vapor pressure, and hygroscopic moisture. Capil-

larity is diminished in clay soils by the addition of salts but increased in sandy soils. Percolation is most rapid in sandy soils and slowest in types, the particles of which are most likely to swell. Fertilizers increase the resistance to percolation. Salts increase or diminish the size of the soil aggregates. Salts, in most instances, increase the cohesion of soil particles as well as apparent sp. gr. Hygroscopic moisture is increased by the addition of salts, with few exceptions. Vapor pressure is lowered in most cases.

B. E. B.

The quantitative determination of mono-, di-, and tricalcium phosphates and their application. GEO. A. OLSON. Washington Agr. Expt. Sta., *Bull.* 116, 1-18 (1914).—O. criticizes the use of NH_4 citrate for detg. available P_2O_5 as being empirical and inaccurate. Substances sol. in NH_4 citrate are not necessarily mono- and di-Ca phosphates; tri-Ca, Fe and Al phosphates are also sol. in this soln. " NH_4 citrate-soluble" is not a measure of available P_2O_5 . If it is desirable to estimate the mono-, di- and tri-Ca phosphates, this can be done by dissolving the substance in HNO_3 and pptg. the soln. with NH_4OH . For the mono-Ca phosphate $\frac{1}{2}$ of the P_2O_5 will be present in the filtrate and for the di-Ca phosphate $\frac{1}{3}$ the P_2O_5 will be present in the filtrate. The NH_4OH method is applicable for the testing of the purity of phosphate chemicals. It can also be applied to differentiate between the different forms of P_2O_5 that may be present in soils, plant, and animal tissue. Indirectly, by adding the equiv. of a base with Ca the different forms of phosphate salts can be detd. In soil, mono- and di-Ca phosphates tend to react, forming tri-Ca phosphate. There is then nothing to be gained by applying either superphosphate or reverted phosphoric acid to soil.

R. C. ROARK.

Some facts about commercial fertilizers in New York State. L. L. VAN SLYKE. New York Agr. Expt. Sta., *Bull.* 392, 585-625 (1914).—The following points are discussed: (1) compn. of fertilizers and cost of plant-food constituents; (2) relation of guaranteed to actual compn. in fertilizers; (3) some defects in the present New York State fertilizer law.

R. C. ROARK.

Comparison of magnesian and non-magnesian limestone in rotation experiments. JACOB G. LIPMAN, *et al.* New Jersey Agr. Expt. Sta., *Bull.* 267, 5-40 (1914).—Five-yr. rotation tests were made. Both forms of lime resulted in an increased crop yield. The yields were usually somewhat higher with the magnesian than with the non-magnesian limestone. In the great majority of cases, the dry matter of the crops from the limed plots showed a higher % of N than that from the unlimed plots.

R. C. ROARK.

The composition of root crops grown in Sweden. H. G. SÖDERBAUM. *Centr. för För. på Jord. Stockholm* 96, 1-25 (1914); *Biedermanns Zentr.* 44, 100-3 (1915).—Analyses of both tops and roots of rape and turnips were made to det. the % of ash, total and proteid N, P_2O_5 , K_2O and CaO. From the results obtained a table was prepared, showing how much of each of the above substances is removed from the soil by a small, medium, and large crop. If the amt. of P_2O_5 taken up is used as a unit, turnips remove 2.7 parts N, 6.2 K_2O , and 2.1 CaO, while rape removes 2.4 parts N, 3.5 K_2O and 1.4 CaO. These values agree quite closely with those given by Lierk.

C. F. MILLER.

Effect of certain organic compounds on wheat plants in the soil. Preliminary paper. F. W. UPSON AND A. R. POWELL. *J. Ind. Eng. Chem.* 7, 420-2 (1915).—This paper deals with the behavior of vanillin, salicylaldehyde, cumarin, quinone and dihydroxystearic acid. No definite conclusions were reached.

ISADOR MILLER.

The action of different nitrogen fertilizers in comparison with liquid manure and nitrogen compounds from air. W. KROGER, H. ROEMER AND O. RINGLEBEN. *Berichte der Landes.* 1914, *Hefi* 34, Sept. 43 pp. (1914); *Chem. Zentr.* 1915, I, 394.—The expts.

covered 3 yrs. and were conducted with barley, oats and potatoes. Though regarded as inadequate on account of their extent and unfavorable weather, the expts. led to the following conclusions: $\text{Ca}(\text{NO}_3)_2$ is in general at least comparable to NaNO_3 ; $(\text{NH}_4)_2\text{SO}_4$ is in general less active. With oats $(\text{NH}_4)_2\text{SO}_4$ is comparable to NaNO_3 , but with potatoes it is less efficient. CaCN_2 behaves like $(\text{NH}_4)_2\text{SO}_4$. In the case of potatoes, liquid manure showed little action. The favorable action of $\text{Ca}(\text{NO}_3)_2$, especially in the case of potatoes, is very striking. The results are given in tables.

M. X. S.

The action of calcium nitrate and sodium nitrate. Field experiments of the year 1912. O. REITMAIR. *Z. landw. Versw.* 17, 729-807(1914).—A summarizing presentation of fertilizer expts. undertaken by a large number of agriculturists.

L. J. GILLESPIE.

Manurial experiments with decomposition products of calcium cyanamide. H. KAPPEN. *Landw. Versuchs-stat.* 86, 115-36(1915); *J. Chem. Soc.* 108, II, 203.—Expts. in small garden plots, on the growth of mustard manured with different forms of N. The yield with carbamide, prepared from Ca cyanamide (Kappen, *Habilitationschr.*, Jena, 1913), was between those obtained with NaNO_3 and $(\text{NH}_4)_2\text{SO}_4$, while carbamide nitrate gave much lower results; guanidine nitrate gave the smallest yields. The relatively low results obtained with carbamide nitrate were due to the presence of a considerable amt. of dicyanodiamidine, produced from dicyanodiamide. The results of an expt. in which dicyanodiamidine was added to soil showed that very little NH_3 was formed in 3 days, and that no further increase was found in 10 days.

E. H. WALTERS.

Nitrogen utilization in field and cylinder experiments. JACOB G. LIPMAN, *et al.* New Jersey Agr. Expt. Sta., *Bull.* 268, 5-25(1914).—In expts. with barley and buckwheat to det. the influence of the mechanical compn. of the soil on the availability of NaNO_3 and dried blood, it is shown that when sand was mixed with shale soil (Penn. loam) in varying proportions, the yield of dry matter and the % of N recovered from NaNO_3 were greater with 10 to 70% of sand than they were with the shale soil alone, or with 80, 90 or 100% of sand. The highest yield of dry matter and % of N recovered occurred with 50% of sand. With dried blood the yield of dry matter and the % of N recovered were higher in pure sand, and in all dilns., than with the shale soil alone. With the first crop, barley, the highest av. yield of dry matter and N were from the NaNO_3 cylinders; with the residual crop of buckwheat, from the dried blood cylinders. In expts. on the continuous growing of wheat and rye, with and without legumes, the 1913 results show that the yields of grain were just about twice as great from the legume plots as from the non-legume plots. In order to test the influence of bacteria supplied in manure on the decompn. of green manure, legume and non-legume, plots were grown in corn, followed by crimson clover or rye. In the legume section the plots receiving manure showed little or no increase over the check plot; but in the non-legume section in every case the plots receiving manure showed an increase over the check plot. The increase is not, however, proportional to the amt. of manure applied, showing that the bacteria conveyed in small quantities of cow manure are instrumental in bringing about a more rapid decompn. of the green manure crop, and thus make available more N for the succeeding crop. If the green manure crop consists of legumes, the additional N thus secured tends to obscure the effects of the manure.

R. C. ROARK.

Lime sensitiveness of lupines and their inadaptability to heavy soils. ADOLFO CAUDA. *Staz. sper. agrar. ital.* 47, 727-32(1914).—Yellow lupines grown in pots on an argillo-humiferous soil supported in the first vegetative stage 10% CaCO_3 , but were damaged by 2% CaO, by 5% pptd. phosphate, or by 5% $\text{CaH}_2(\text{PO}_4)_2$. The bad action

of the last was quite eliminated by addition of CaCO_3 , and in part neutralized by KCl . Heavy soils proved capable of supporting a good vegetation of lupines.

L. J. GILLESPIE.

Fertilization of coffee. ANON. *India Rubber J.* 49, 424 (1915).—During the growth of the berry there is a markedly steady increase in the % of potash; from this it is concluded that potash in an available form is needed all the time. The N content of the berry also increases steadily during the growth of the berry. On the other hand, the P_2O_5 content appears to be more const. in quantity, and reaches a max. in October; hence the P_2O_5 is needed in an available form in the beginning of the season.

EDWARD J. KELLEY.

Fertilizers, feeds and fungicides. J. W. INCE. *North Dakota Special Bull.* 3, No. 9, 140-51.—Results of analyses of fertilizers, stock feeds, lead arsenates, Paris greens, etc., are presented in tables. As a result of spraying tests upon 150 small plots of potatoes it is shown: (1) that lead arsenate and zinc arsenite are superior to Paris green in adhesive power. Soap, glue, the carbonates of Fe, Pb and Zn, and apparently flour and slaked CaO , increase the adhesive property of sprays. (2) Sulfur sprays are not suitable for potatoes. (3) No effect upon "tip burn" was noticed. (4) The combination of arsenicals and fungicides seem to be quite effective in prolonging the life of the vines.

R. C. ROARK.

The application of insecticides containing arsenic and lead. G. SONNTAG. *Arb. kais. Gesundh.* 49, 502-20 (1914); *Chem. Zentr.* 1915, I, 450-1 (1915).—Expts. were carried out with various insecticides and fungicides to det. whether or not any of the substances injurious to health are taken up by the fruit and leaves, and how long they are retained after their application. Arsenic was found in weighable quantity in gooseberries, currants, apples and pears 41 to 87 days after its application with Bordeaux mixture. It was also found in 5 out of 8 samples of leaves analyzed 87 days after double spraying. Both As and Pb were found in weighable quantities in grapes and stone fruits 24 days after application of a As-Pb spray; in gooseberries and currants, 39 days after spraying; out of 3 samples of apples and pears investigated, As was found each time and Pb once, 80 days after spraying. Upon treatment with As-S dust, As was found in 7 out of 7 and Cu in 4 out of 7 samples of grapes and stone fruits after 24 days; both As and Cu were found in currants and gooseberries 39 days; and in pears and apples 106 days after treatment. The analytical procedure used is described in detail.

Fr., 18,325, Oct. 14, 1913, addition to 462,357 (C. A. 8, 2917). CHEM. FABRIK RIENANIA and A. MESSERSCHMITT. In mfg. fertilizers from natural K silicates and phosphorites, the required amt. of lime for the disintegration of the rock is replaced in part by soda, whereby concd. products and low reaction temps. are secured. Leucite (100 kg. of 18% K_2O), phosphorite (100 kg. of 40% $\text{Ca}_3(\text{PO}_4)_2$, and 60% CaCO_3), CaO 15 kg., and Na_2CO_3 10 kg., are fused together. The citrate-sol. product contains 8% K_2O and 10% P_2O_5 . By operating in 2 phases (disintegration by lime) phosphorites low in lime may be employed.

Ger., 281,012, Nov. 28, 1912. H. NAEGBEL. Mfg. enriched phosphate fertilizer. See Fr., 455,926 (C. A. 8, 1636).

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

The forms of combination of sulfur in wine and their determination. W. I. BARAGIOLA AND O. SCHUFFELI. *Wädenswil. Z. Nahr.-Genussw.* 29, 193-221 (1915). —A comprehensive review and discussion of the literature relating to the detn. of the different S compds. in wine are given together with the results of expts. by the authors in trying the various methods that have been proposed. In the detn. of total S, the chief sources of error were found to be absorption of S through the employment of illuminating gas for burners during ignition and the use of insufficient oxidizing agents to prevent loss of S through reduction by incandescent C. In the detn. of organic sulfates such as $\text{KC}_2\text{H}_3\text{SO}_4$, 100 cc. of wine must be boiled for 1 hr. with 25 cc. of concd. HCl in order to hydrolyze the $\text{C}_2\text{H}_3\text{SO}_4$ group. Weaker acid produces incomplete hydrolysis. In the sepn. of free and combined SO_2 , methods which provide for the oxidation of the free SO_2 , volatilization of the combined SO_2 , and subsequent pptn. in the residue of the S representing the free SO_2 by means of BaSO_4 yield high results if H_3PO_4 is employed for acidifying previous to distn. This can be avoided by the use of HCl instead of H_3PO_4 . H_2O_2 was found to be more convenient than I for oxidizing SO_2 in the distillate in the detn. of total and combined SO_2 . The methods and scheme of computation finally adopted are as follows: *Total S*: Render 50 cc. of wine alk. with Na_2CO_3 , add 0.5 cc. of Merck's Perhydrol, evap. to dryness, add a little KNO_3 , and ignite; treat the ash with HCl, take up in water and filter, pptg. as BaSO_4 in the usual way. Use only C_2H_4 burners for heat throughout the entire process. *Total H_2SO_4* : Boil 100 cc. of wine with 25 cc. of concd. HCl for 1 hr. in a const. stream of CO_2 ; cool, neutralize with NH_4OH , acidify with 2 cc. of HCl and ppt. as BaSO_4 in the usual way. *Inorganic H_2SO_4* : Acidify 125 cc. of wine with 100 cc. of dil. HCl (8 cc. conc. HCl and 92 cc. water), and add, without stirring, 25 cc. of 5% BaCl_2 soln. Allow to stand for 2-3 hrs. in an atm. of CO_2 , decant the clear supernatant liquid through a filter (1st filtrate), add 150 cc. of water and 2 cc. conc. HCl to the residue in the pptg. vessel, digest for a while upon a steam bath and then bring the ppt. upon the filter, wash, ignite and weigh. *Organic H_2SO_4* : To 125 cc. of the first filtrate from the last operation add 20 cc. of conc. HCl and boil in a current of CO_2 for 1 hr.; cool, neutralize with NH_4OH , acidify with 2 cc. HCl and ppt. as BaSO_4 in the usual way. *Total SO_2* : Acidify 100 cc. of wine with 2 cc. of conc. HCl and distil in an atm. of CO_2 , collecting the distillate in 0.5-1.0 cc. of the perhydrol dild. with a little water, a second receiver containing I-KI soln. being placed beyond the first. Ppt. the H_2SO_4 contained in the two receivers as BaSO_4 in the usual way. *Combined SO_2* : To 100 cc. of wine contained in a vessel filled with CO_2 add a little starch paste and titrate with 0.02 N I soln. until a slight excess is present; then add as much 0.02 N Na_2AsO_3 as has been used of the 0.02 N I, acidify with 2 cc. conc. HCl, and distil the combined SO_2 as in the last operation. *Free SO_2* : Ppt. the H_2SO_4 remaining in the residues from the distn. of both the total and combined SO_2 , the difference representing free SO_2 . *Neutral S* (representing free S and S in combinations other than the above, the nature of which is unknown): Treat 100 cc. of wine with 25 cc. conc. HCl, boil for 1 hr., ppt. the total H_2SO_4 as BaSO_4 , filter, add HNO_3 to the filtrate, and evap. to dryness, adding a little HNO_3 from time to time. Treat the residue with fuming HNO_3 , remove HNO_3 by evapg. several times with HCl, take up in water, filter, ignite and weigh the ppt. of BaSO_4 representing the so-called neutral S. In computing the balance of S compds, the sum of S as inorganic and organic H_2SO_4 , free and combined SO_2 , and neutral S as found by sep. detns. should balance the detn. of total S. The sum of free and combined SO_2 as found by sep. detns. should balance the detn. of total SO_2 . The sum of inorg. and org. H_2SO_4 should balance the detn. of total H_2SO_4 . No difficulty is experienced with this scheme except

in the case of incompletely fermented wines and fruit juices containing invert sugar when the partition of SO_2 into the free and combined forms is apt to be uncertain.

A. F. SEEGER.

The clouding of wines through iron phosphate compounds. H. WEIL. *Z. Nahr.-Gewissm.* 29, 60-6 (1915).—An exam. of the sediments in 6 different wines showed them to be ferric phosphate compds. W. carried out a series of expts. to det. the cause of this pptn. and found that SO_2 had no effect on its formation; that in the presence of free acids that ionize, such as tartaric and malic, the ppt. would dissolve, but that lactic and succinic acids did not affect it. If a wine clouded with Fe phosphate compds. be exposed to the light the ppt. dissolves but on standing in the dark for a few days it will reappear. He explains this photochem. reaction as due to the reduction of Fe^{++} compds. to Fe^+ under the influence of light, these being reoxidized to Fe^{++} when kept in the dark. If the Fe originally present in the wine was in the Fe^+ state no ppt. of phosphate is formed until the air oxidizes it to the Fe^{++} state. Through bacterial action malic acid is broken down to lactic acid and CO_2 , causing the pptn. of Fe phosphate compds.

Stability of aqueous solutions of sulfurous acid. P. FÖRSTER. *Arb. kais. Gesundheits.* 49, 468-87 (1914); through *Chem. Zentr.* 1915, I, 447.—P. investigated the stability of SO_2 under different methods of manuf. and the influence of the condition of water used for its absorption and kind of storage vessel, i. e., the presence of greater or smaller quantities of positive catalysts. Further, he sought to det. whether by addition of negative catalysts and by the manner of storage the stability of SO_2 solns. can be increased; especially the conditions most favorable to preserving stability of SO_2 solns., which should be stored for prolonged time (over a year) were investigated. The expts. led to the conclusion that the stability of aq. SO_2 (not too dil.) is in general far greater than usually assumed. The loss of SO_2 is nearly exclusively due to volatilization and not to oxidation. Solns. in fully filled and well closed bottles proved sufficiently stable if kept at moderate temps. (in cellar or ice-box). Neither water accelerated nor alc. retarded oxidation of SO_2 . In employing conductivity water the loss of SO_2 due to oxidation was only half that with hydrant or distilled water.

L. W. HAAS.

Proteolytic enzymes in malt. EMIL WESTERGAARD. *J. Inst. Brewing* 21, 344-55 (1915).—W. attempted to det. to what extent the proteolytic enzymes in malt are active under the conditions prevailing in a brewer's or distiller's mash tun. For this purpose 1.0 to 1.2 kg. malt was used in each expt. The malt was finally ground and further disintegrated by being triturated with an equal wt. of sand in a large mortar, sufficient water being added to form a dough. The liquid was then expressed, employing 300-350 atm. pressure. By this method it was possible to obtain a liquid containing nearly all the sol. constituents of the malt with very little of the products of the various enzymic reactions. The liquid was immediately freed from suspended particles by centrifuging. The results from digestion expts. at different temps. show that

the proteolytic activity increases fairly rapidly to about 50°, then more slowly to 56–8°; it then begins to fall, the decrease becoming very marked above 60°. As the av. temp. in a brewer's mashtun is about 65°, and that in a distiller's mashtun not far from 50°, the proteolytic activity is considerably increased in a brewery by lowering, and in a distillery by raising the mashing temps. In a number of expts. with green malt the presence of peptolytic activity was sought. Exts. were made from the ground malt with CHCl_3 -water and the residues ground with sand and expressed as previously described. Both exts. were allowed to act partly upon Witte peptone and partly upon Roche peptone at different temps. In both cases the optimum temp. lies between 25 and 37°. The results show clearly the existence of two forms of peptolytic activity; one rises sharply from nothing in the ungerminated seed till it reaches its max., whereupon it remains fairly const., while the activity in the second form rises comparatively slowly from slightly above zero in the ungerminated seed till it reaches its max. a few days later than in the first named form, after which it rapidly falls again. One of these peptolytic enzymes is destroyed at 50°, while the activity of the other is greatly decreased at that temp. Neither of them seem to be active under the conditions existing in a brewer's mashtun, but one of them may exercise some influence in a distiller's mashtun. So far as brewing is concerned, it is therefore obvious that the quantity of polypeptides is largely regulated by the mashing temp., while the quantity of amino acids is, under normal circumstances, solely detd. by the malting process. From expts. with yeast it is seen that brewer's yeast possesses extremely little proteolytic activity; the peptolytic activity, however, is extremely pronounced. The presence of unmodified proteins and amino acids and the activity of peptases during the mashing process are accordingly unnecessary for the development of the yeast. On the contrary, the presence of these substances might be a source of considerable danger due to strongly favoring bacterial growth. It seems possible that in this there is at least a partial explanation of many hitherto unexplained facts, such as instability of beers made from slack malt, or from malt which during the drying process had been kept comparatively long at low temp., or finally, beers which have been mashed at temps. most suitable for peptolysis.

L. W. HAAS.

Distribution of phosphoric acid in malt. F. SCHÖNFELD AND H. KRUMHAAR. *Wochschr. Brau.* 32, 101–3, 114–6(1915).—It is shown that boiling with alc. for several hrs. to check the action of the enzymes present in malt leads to entirely erroneous results. Such treatment effects extensive changes in the distribution of phosphorus pentoxide. The influence of enzymic action was found to be very slight if the malt meal was extd. directly by ice-cold distd. water. Comparative detns. with malts which had been extd. in this way for 2 to 6 hrs. gave fairly const. values for the alk. earth, alkali and total sol. P_2O_5 content, so that the authors recommend detg. these without any preliminary treatment of the malt.

L. W. HAAS.

Notes on caramel. W. A. HANDCOCK. *Brewers' J.* 51, 167–9(1915).—Certain caramels which appear perfectly satisfactory under the usual tests and with fairly strong worts, will form an amorphous deposit when mixed with weaker worts. Analysis of a sample of such deposit showed 5.1% N, suggesting a combination of caramel and protein matter. Expts. with invert sugars also showed that many specimens will produce a bad "haze" when mixed with second wort. To avoid trouble caramels and sugars should be divided between the various coppers. Samples of caramel which give a ppt. with waters contg. $\text{Ca}(\text{HCO}_3)_2$ are too unstable to be satisfactory for brewing purposes.

Malt and beer. F. P. SIEBEL. Master Brewers' Assn., U. S. A. *Western Brewer* 44, 80–5(1915).—A lecture.

L. W. HAAS.

Stability of some yeast enzymes. A. BAU. *Wochschr. Brau.* 32, 141-3, 151-4, 159-62(1915).—To the most resistant enzymes in yeast belong invertase, maltase and melibiase (the latter with bottom fermenting yeasts only), further emulsin, amygdalase, carboxylase (if a salt of $\text{CH}_3\text{COCO}_2\text{H}$ is used as reagent), lipase, and endotryptase. Carboxylase is sensible to strongly acid reaction, for only yeasts of high fermentative capacity cleave $\text{CH}_3\text{COCO}_2\text{H}$. One of the most sensitive enzymes apparently is trehalase; oxidase is also very unstable. The order in which the yeast enzymes are to be enumerated according to their stability cannot be decided at present. As to the quantity of these enzymes, it is rather certain that in fresh yeasts zymase, invertase, maltase, melibiase, carboxylase and catalase are present plentifully, then follow endotryptase, oxidase and reductase, while trehalase, emulsin, amygdalase, lipase, and yeast rennet are only present in minute quantities. Only yeasts from German practice were examd.

L. W. HAAS.

Contribution to the chemistry of malt, with special reference to the lipoids. H. LÖNN. Kgl. Technische Hochschule, München. *Dissertation* 1914; *Z. ges. Brau.* 38, 97-101, 106-11, 116-20, 123-5(1915).—The extensive exptl. work which cannot be briefly abstracted may be summarized as follows: If malt is extd. with 80% alc., there are dissolved (1) the protein bynin, (2) considerable quantities of invert sugar and sucrose, (3) roast and aroma substances, (4) fats distinguished by a high content of free fatty acids, (5) a lipid, which according to its P- and N-content belongs to the group of diaminophosphatides (N:P = 2:0.94). It is especially distinguished by a high sucrose content (1.02%). This phosphatide proved to be a secondary product, as is shown by comparison with the lipid obtained by extg. the same malt with C_2H_5 . No clear insight as to the changes of the phosphatides during malting could be gained. Apparently they have little practical significance; they possibly take part in the formation of aroma. In this connection the relations and behavior of phosphatides to carbohydrates were studied. It was found that phosphatides dissolved in organic solvents are able to take up considerable quantities of sucrose provided the latter is insol. in the solvent (that used was C_2H_5). This taking up of sucrose follows an absorption curve and is conditioned by the colloidal nature of phosphatide solns. with organic solvents. An exam. of fat of malt and barley proved that the fatty acids consist of stearic, palmitic, oleic, linoleic and linolenic acids; in the unsaponifiable matter sitosterin, para-sitosterin and a hydrocarbon, probably $\text{C}_{18}\text{H}_{38}$ (octadecane), were identified.

L. W. HAAS.

Germ-destroying power of ultraviolet rays applied to sterilization of water and disinfection of trade packages in breweries. E. MOUFANG. *Kirn a. d. Nahe. Allgem. Z. Bierbrau. Malsfab.* 43, 151-5(1915).—From his expts. M. concludes that by the application of ultraviolet rays for sterilizing barrels (by means of a specially constructed quartz lamp which could be moved through the bung hole) the biological condition of pitched barrels may be greatly improved, but that perfect sterilization in a biological sense is not obtained by the present appliances. L. W. HAAS.

Investigations on hops. VI. Amount of lupulin in plants raised by crossing. J. SCHMIDT. *Compt. rend. lab. Carlsberg* 11, 165-83(1915); cf. *C. A.* 9, 688, 1657. —The relation between the lupulin percentage of the mother plant and that of the offspring varies greatly according to the lupulin content of the mother plant. VII. **Employment of artificial light in titration of the hop resins.** SVEND HÖRG LARSEN. *Ibid* 184-7. —To carry out titrations in artificial light L. employs a titration table which consists of a wooden box (13 X 18 X 14 cm.), the upper side of which has been removed and replaced by a removable plate of ground glass, which is illuminated from below by an elec. lamp. For the purpose a metal filament lamp of 25 c. p. was found most practical. The box is arranged to open sideways to facilitate the removal of the lamp.

Comparative detns. showed that this method of titration is by no means inferior in accuracy to titrations in daylight. VIII. Flowering time of plants raised by crossing. J. SCHMIDT. *Ibid* 188-98. L. W. HAAS.

Rewards for methods of utilizing alcohol. *Chem. Eng.* 21, 220(1915).—The Russian government offers prizes totaling \$136,475. E. J. C.

Use of raw sugar in distilleries. K. WINDISCH. Inst. Hohenheim. *Z. Spiritusind.* 38, 121-2, 129-31(1915).—W. gives an account of experiences in working up sugar alone and with admixts. of different proportions of various other raw materials. The raw sugar is to be dissolved in hot water (minimum temp. 75°), the resulting soln. being practically sterile. It is necessary to acidify pure sugar mashes. Lactic acid did not prove superior to H_2SO_4 for this purpose; 1.5 cc. concd. H_2SO_4 (As-free) per 1 kg. sugar is recommended. If sugar is mashed together with other raw materials acidification is not absolutely necessary; not even previous neutralization of the sugar soln. is necessary, if a larger quantity of the other material is used. No advantage is attained by inverting the sucrose by acid previous to pitching the mash with yeast. To ensure most favorable conditions of fermentation a mash is required of a concn. below 17% with abundant nutrition for yeast, and a warm fermentation. Fermentation is started at such a temp. that the max. (30°) is reached as soon as possible and at which the fermentation should be completed as far as possible. If the temp. drops quickly all chances of a satisfactory final fermentation are lost. The most suitable proportions of raw sugar and other raw materials (potatoes, sugar beets and corn) for compound mashes are recorded and many directions are given with reference to a successful fermentation and distn. and to the culture of yeast adapted to such changed conditions. L. W. HAAS.

Results of working raw sugar in distilleries. W. BÜCHLER. Weihenstephan-Munich. *Z. Spiritusind.* 38, 129(1915).—B. reports on expts. carried out with sugar alone and with admixts. of potato mashes in various proportions. Cf. preceding abstr. L. W. HAAS.

Complete fermentation of rather concentrated raw sugar solutions by yeast which is nourished by mineral salts exclusively. C. NAGEL. *Z. Spiritusind.* 38, 122-3 (1915).—Yeast is not able to ferment solns. of raw sugar completely if no yeast nutrient is added. N. obtained a satisfactory yield of alc. (58.44 l. abs. alc. per 100 kg. raw sugar, first quality) with 16% sugar solns., if there was added 0.9 kg. $(NH_4)_2SO_4$, 0.3 kg. $NH_4H_2PO_4$, 0.6 kg. K_2SO_4 , 0.4 kg. cryst. $MgSO_4$, and 0.3 kg. $CaSO_4$ per 1000 l. mash. The first 4 salts are dissolved in about 20 l. lukewarm water; $CaSO_4$ is separately suspended in much water (about 10 l.). Mash and salts are well mixed. The yeast which was added in the proportion of 1.5 kg. per 1000 l. soln. developed and multiplied plentifully (giving a crop yield of 7.8% of wt. of sugar employed). L. W. HAAS.

The working up of raw sugar into spirits and brewer's yeast. OTTO REINKE. Braunschweig. *Chem. Ztg.* 39, 149(1915).—A 92% sugar in 20% soln. after preliminary treatment with acid and the addition of malt, etc., or of 20 kg. brewer's yeast per cu. m. soln., of which 18 kg. has been heated for 2 hrs. at 68°, will yield about 58 l. alc. per 100 kg. sugar. J. H. MOORE.

Working up sugar beets into alcohol. F. EHRLICH. *Z. Ver. Zuckerind.* 65, 70-5(1915).—At present it may be commercially feasible (in Germany) to make alc. from sugar beets. The beets are heated 1-1.5 hrs. with steam at 2 atm.; this softens them so that the mass can be blown through perforations to give a product that can be directly fermented. A top yeast is used; considerable foam is formed, which is the chief difficulty. The alc. so formed is not inferior in quality to that from potatoes. It contains little fusel oil. From 100 kg. beets of 16% sugar, 9 to 10 l. of alc. may be prepd. The slop is as readily eaten by cattle as potato or grain slop. W. L. BADGER.

Comparative experiments on fermentability and yield of alcohol of refined sugar and raw sugar. G. FOTH. *Z. Spiritusind.* 38, 138-9(1915).—The fermentation of mashies from refined sugar was (even with large quantities of pitching yeast in association with larger amts. of yeast nutriment) more sluggish than that of those from raw sugar. With small quantities of pitching yeast (5 g. per l. sugar soln.) and without yeast nutriment, even after 5 days no complete fermentation was attained with both sugars; but while in this time only 41% of the refined sugar was fermented, 98% of the raw sugar was transformed. Employing larger quantities of yeast (10 g. per l.) without yeast nutriment, raw sugar fermented completely in 4 days, refined sugar to only 77.5% in 5 days. Complete fermentation of refined sugar is only attained if yeast nutriment is added, but the time required is 5 days (for raw sugar under the same conditions only 2 days).
L. W. HAAS.

Influence of cellar treatment on acid retrogression in wine. C. SCHÄTZLEIN. (Neustadt a. d. Haardt) AND O. KRUG (Speyer). *Arb. kais. Gesund.* 49, 521-9(1914).—The influence of time of racking, "stirring up" of settled yeast, and sugaring were investigated. The expts. confirmed the authors' opinion that it is possible by observing the different cellar technical measures favoring the biological acid degradation, to improve even very poor vintages to marketable products without violating the legal regulations.
L. W. HAAS.

Molasses as a source of alcohol for the production of power. T. H. P. HERRIOT. *J. Soc. Chem. Ind.* 34, 336-40(1915).—The suitability of alc. for generating power in the internal-combustion engine has been sufficiently established by exact tests and practical experience and there is little doubt that alc. could be substituted for petrol and coal in most sugar-producing countries. The possible production of alc. from cane and beet molasses is about 200,000,000 gal. per year. If the K and N in molasses are recovered after fermentation and production of alc., their fertilizing value covers all expenses of distn., leaving alc. as a by-product free of cost. According to different authorities the cost of manufacturing 95% alc. without recovering K and N, and excluding the cost of molasses itself, is stated as follows: 8 c. per gal. in U. S. A., 5 c. in Demerara (exclusive of fuel), 10.2 c. in Hawaii and 10 c. in Cuba. L. W. HAAS.

Experiments on diastase (BOKORNY) 11A.

DILBECK, M., et al.: *Illustriertes Brenner-Lexikon*. Berlin: P. Parey. 790 pp. 28 M.

U. S., 1,139,507, May 18. P. G. HESTRÖM. Apparatus for fermenting sulfite liquors to obtain alcohol. Cf. C. A. 8, 2251, 2803.

U. S., 1,140,882, May 25. R. DE FAZ. Alcoholic fermentation of saccharin solutions is carried out under the influence of ultraviolet light, using yeast cultures which have been acclimated to the ultraviolet light. This treatment facilitates the alc. fermentation and retards some undesirable secondary fermentations.

Brit., 849, Jan. 12, 1914. Addition to 9,170, 1913 (C. A. 8, 3343). E. W. KUHN. In brewing the mashing process described in the principal patent is modified as follows: The mash, prep'd. in the cold and after removal of some of the ext., is heated to 80° to coagulate the albumins, but to prevent the coagulation taking place around the starch granules. The mash is boiled and cooled to 70-80° so as to destroy the dextrinase but not the amylase.

Brit., 1,335, Jan. 17, 1914. R. DE FAZI. Alcoholic fermentation is carried out in the presence of ultraviolet light, either sunlight or rays from uvioi lamps, or by yeast which has been cultivated under the action of ultraviolet light. The lamps may be im-

mersed in the liquid, or the fermenting vats may be made of uvial glass. The liquid may be decolorized before treatment. Cellulose in the form of torn filter-paper or the like is added to the fermenting liquid and forms a layer on the top.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Determination of the hydrastine content of rootstocks and extracts of *hydrastis canadensis* L., according to the methods of the different pharmacopeias and a new method for the quantitative determination of berberine in extracts. L. DAVID. *Pharm. Post* 48, 1-4, 21-3(1915).—(1) At 15°, hydrastine is sol. in 227 parts Et₂O, 22727 parts petr. ether (b. 40-60°), 11628 parts petr. ether (b. 50-85°), 18 parts C₆H₆ and very sol. in CHCl₃. (2) Comparison of the methods for the detn. of hydrastine in exts. in the different pharmacopeias shows that the German is the best, the Belgian fairly good, the Hungarian not so good, and that the Dutch, French, Swiss, and the U. S. (IX) are not usable. (3) The U. S. equals the German in accuracy if the alc. is evapd. off before shaking out with Et₂O. (4) In the detn. of hydrastine the following points are important: (a) Alc. should be evapd. from the ext. before shaking out with Et₂O; otherwise too much extractive is taken up. (b) Berberine should be pptd. with HCl or KI. If HCl is used the ext. should be shaken with talc and filtered to remove the berberine-HCl and the coloring matter; too much HCl should not be used since it will cause the talc to take out the hydrastine also. (c) The ethereal soln. should be dild. with petr. ether and shaken with powdered tragacanth to remove the H₂O. (5) The methods in the German and Belgian pharms. for the detn. of hydrastine in rootstocks are both accurate. (6) Berberine detn.: ppt. berberine and hydrastine with potassium bismuth iodide reagent, dissolve the hydrastine ppt. with EtOAc, liberate the berberine in the residue with 10% NaOH, shake out with Et₂O-CHCl₃ mixt., evap. and weigh. C. O. EWING.

Blood charcoal. F. WISCHO. *Pharm. Post* 48, 73-4(1915).—The more voluminous a blood charcoal is the greater is its power of adsorption for coloring matter, and also for toxins, bacteria, etc. Therefore only very light finely powdered blood charcoal should be used for medicinal purposes. Blood charcoal, after being shaken with blood serum, mucilage, pepsin-HCl or carbohydrates, still retained its power of decolorizing a methylene blue soln. The activity of the charcoal seems therefore not to be affected when administered internally. Since it is sometimes used internally it should be tested as follows for cyanogenetic compds. which may be formed in its prepn.: ash some of the charcoal with powdered Fe, ext. the ash with H₂O, filter, to filtrate add FeCl₃, FeSO₄ and HCl; no blue color should appear. C. O. EWING.

Determination of alcohol in pharmaceutical preparations. A. REUSS. Dresden. *Pharm. Zentralhalle* 56, 61-8(1915).—Richter (cf. C. A. 8, 3218) shakes out ethereal oils with NaCl soln. and petr. ether before distg. R. modifies Richter's method by first adding an alkali to prevent volatile acids from distg. over. The whole alc.-H₂O soln. is used for the distn. after the ethereal oils have been removed instead of an aliquot portion as recommended by Richter. C. O. EWING.

Microscopic studies of the reaction of cacao seeds and myristica seeds (nutmegs) to several unknown (little used) reagents. HANS FREUND. *Pharm. Zentralhalle* 56, 83-5, 91-3(1915).—Descriptions are given of the microscopical appearance of the seed before and after treatment with clove oil and solns. of I-KI, Cl-ZnI₂, picric acid, nigrosin and carbolfuchsin. C. O. EWING.

Russian barley ergot. A. SCHNEIDER. *Pharm. Zentralhalle* 56, 101(1915).—Russian ergot from barley has the normal color of ergot; the size is about that of the

barley grain; the color is lighter than that of rye ergot, often being as light as the barley itself. It may therefore be easily detected in official ergot. C. O. EWING.

Hesperidin and the crystals in *Hyssopus officinalis*. O. TUNMANN. *Pharm. Zentralhalle* 56, 135-41 (1915).—Although hesperidin has been reported to be present in a number of plant families, up to the present its presence has been proven with certainty both microscopically and macroscopically only in the Rutaceae and Umbelliferae. T. has positively demonstrated its presence in the Labiatae also, having obtained pure ash-free hesperidin (m. 252°) from *Hyssopus officinalis*. The hesperidin was colorless (white), did not reduce Fehling soln. and hydrolyzed only upon boiling 6 hrs. with dil. H_2SO_4 . It was easily sol. in pyridine, slowly sol. by heating in AcOH and $\text{C}_6\text{H}_5\text{NH}_2$, insol. in CHCl_3 , Et_2O and Et_2O -alc., easily sol. with a yellow color in dil. alkalis, insol. in dil. mineral acids. T. holds that hesperidin is a by-product of the plant metabolism. Expts. are in progress to det. why hesperidin crystals were still visible with a microscope in *Citrus* and *Hyssopus* after 40 years, while in *Verbascum* and *Tilia* they had disappeared, and to det. whether the method of drying alone influences the decompn. of the very stable hesperidin or whether it is due to the action of other substances. C. O. EWING.

Use of carbon tetrachloride in the extraction and estimation of the active principles of drugs and medicinal plants. GIULIO GORI. *Siena. Boll. chim. farm.* 52, 891-5 (1913); cf. *C. A.* 8, 1440.—In pursuance of his previous suggestion that CCl_4 be substituted for various solvents which are usually employed (especially CHCl_3) in toxicology, G. has detd. the solubility at 20° of a number of alkaloids in CCl_4 . The number of g. caffeine, theobromine, quinine, strychnine, brucine, cocaine, atropine, morphine, codeine, papaverine, narcotine and narceine which were sufficient to sat. 100 g. of CCl_4 were, resp., 0.258, nil, 0.544, 0.220, 2.030, 31.942, 1.760, 0.025, 2.940, 0.518, 1.040 and 0.002. The method of extn. by CCl_4 was applied to several substances containing caffeine. Fifteen g. of dry, powdered cola beans were finely pulverized and intimately mixed with 10 g. MgO ; this mixt. was made into a paste with approx. 40 cc. H_2O , dried slowly at $25\text{--}30^{\circ}$ and again finely pulverized. This dry powder was then extd. for 10-12 hrs. with 150 cc. CCl_4 in a Soxhlet extn. app. After the extn. was finished, the solvent was evapd. on a H_2O bath. The slightly rose colored residue was extd. 3 times with boiling H_2O , the aq. soln. was filtered and the filter was washed with boiling H_2O ; the filtrate was evapd. on a H_2O bath and the white, cryst. residue was dried at 100° to const. wt. Fifteen g. of the powdered cola beans (moisture content = 11.70% when dried to const. wt. at 100°) were found by use of CCl_4 as a solvent to contain 0.222-0.244 g. anhydrous caffeine as compared with 0.220-0.242 g. when CHCl_3 was employed as a solvent. The residue from the CHCl_3 ext. was less pure than that left from the CCl_4 soln. and it was necessary to purify the caffeine by dissolving the residue in dil. HCl , filtering, rendering the filtrate alk. with NH_4OH and extg. with CCl_4 (in order to leave behind the theobromine extd. by CHCl_3). From 15 g. powdered green coffee beans there were obtained 0.273 g. and 0.244 g. anhydrous caffeine by CCl_4 and CHCl_3 extn. resp.; the method of extn. by means of CCl_4 was also applied to the detn. of caffeine in tea leaves. In both the CCl_4 and CHCl_3 extns. it was necessary to purify the residue left after evapg. the solvent by extg. it 3 times with boiling H_2O ; the CHCl_3 soln. was much more intensely colored than the CCl_4 soln. Inasmuch as theobromine is practically insol. in CCl_4 (almost wholly so at 18° and to the extent of 1 in 4703 at the b. p.), it is possible to effect a sepn. of caffeine and theobromine by means of this solvent. When 0.25 g. each of caffeine and theobromine were intimately mixed with sand, 0.240 g. and 0.241 g., resp., were recovered by extg. first with CCl_4 and next with CHCl_3 . Twenty g. fluid ext. of cola beans were concd. on a H_2O bath to about $\frac{1}{2}$ the original vol. and made into a paste with 15 g. MgO , this

paste being extd. successively with CCl_4 and CHCl_3 ; 0.059 g. theobromine and 0.314 g. hydrated caffeine were obtained. The applicability of CCl_4 as an extractive agent for other alkaloids will be investigated.

H. S. PAINE.

Color reaction of gelatin. R. LIESEGANG. *Pharm. Praxis; Boll. chim. farm.* 53, 736(1914).—Solns. of tricalcium phosphate and CuCl_2 , when mixed with gelatin, give a violet coloration without turbidity instead of a green ppt.

H. S. PAINE.

Argaldine. ANON. *Dermat. Woch.; Boll. chim. farm.* 54, 70(1915).—This prep. consists of a combination of Ag albuminate with hexamethylenetetramine; formaldehyde is produced by contact with animal tissues. Injections of a 1% soln. of the prep. are proposed in gonorrhea and, in view of the slight irritation produced, a soln. of even 10% strength may be employed.

H. S. PAINE.

Gray oil. P. LAMI. *Formulario farm. osped. maggiore Verona; Boll. chim. farm.* 54, 136(1915).—In order to prep. this oil take equal parts Amer. vaseline and metallic Hg, mix intimately and add sufficient oil of vaseline to yield a mass containing 30% Hg; then add several drops of "gomenol" and $\frac{1}{4}$ the vol. of Et_2O containing 20% camphor, mix and preserve in closed vials. One cc. contains 0.20 g. Hg.

H. S. P.

Oleate of mercury and cholesterol. P. LAMI. *Formulario farm. osped. maggiore Verona; Boll. chim. farm.* 54, 170(1915).—The following prep. has been proposed by Sero on under the name of "mercurio coleolo." It is a simple oil soln. of Hg oleate and cholesterol and is prepd. by taking 7.5 g. Hg oleate (Merck or Kahlbaum) containing 40% Hg, 3 g. cholesterol (or 12 g. of the 25% oil soln. of cholesterol Merck) and sufficient oil of bitter almonds to make 100 cc., then heating and mixing on a H_2O bath until a perfect soln. is obtained. The prep. is preserved in 1 cc. vials; each cc. contains 0.03 g. Hg and 0.03 g. cholesterol. A milder prep. may be obtained by using only 3 g. Hg oleate to 100 cc.

H. S. PAINE.

Content of cornutine in *Secale cornutum* and its extract. H. WASTENSON. *Svensk Farm. Tid.* 36, 602-5(1914).—Applying the Pharm. Helvet. tests for the alkaloid in *Secale cornutum* to the powders of the Swedish plants, W. obtained but meager reactions. From quant. analysis he concludes that the alkaloid content varies with seasonal conditions and locality of growth. Swedish plants gathered in 1911 gave a max. of 0.016; those of 1900, 0.14%. The Spanish and German products ranged from 0.02 to 0.15% alkaloid, whereas the samples from Russia exceeded 0.4%.

A. R. ROSE.

Notes on the British pharmacopeia 1914. C. W. KEMSEY-BOURNE. *Pharm. J.* 94, 521-2(1915).—Under *Acidum acetylsalicylicum* the Brit. Pharm. is silent as to odor. Some com. samples have a strong odor of AcOH , but pure aspirin is odorless. Under *Acidum picricum*, no mention of its explosive property is made. *Ammonii carbonas* cannot be brought up to the official standard. Three com. samples were 81.2-83.9% of the official strength. Infusa do not keep in summer, and should be replaced by weak tinctures. The directions of the Brit. Pharm. for *liquor calcis* and for *syrupus ferri iodidi* lead to understrength preps. Com. *unguentum gallae cum opio* sometimes becomes moldy, perhaps because when it is prepd. in large amts., some makers rub the opium first with a little H_2O so as to get a smooth ointment. When *pulvis gentianae* is overfermented, it gives a low H_2O ext. number. ZnO should not be kept in paper bags. It absorbs H_2O and CO_2 , becoming lumpy and gritty.

S. WALDBOTT.

Pharmacopeia revision. WILLIAM KIRKBY. *Pharm. J.* 94, 548-50(1915).—An historical account of the development of English pharmacopeias.

S. W.

Quinidol, iodized powdered cinchona bark. A. MOUCHET and MALBEC. *Paris médical; Rép. de pharm.* 27, 83(1915); *Pharm. J.* 94, 625.—Quinidol is a mixt. of I

with powdered red cinchona bark, used as an antiseptic dusting powder for wounds. 5 or 10 g. I are dissolved in 100 or 200 g. Et_2O , this soln. is added to 100 g. of the finely powdered bark, and the mixt. is triturated until the Et_2O is evapd. For gangrenous wounds, the 10% mixt. is recommended. It is very effective, and cheaper than CHI_3 .

Crude calcium cyanamide as a raw material for chemical industries. O. B. CARLSON. *Z. angew. Chem.* 27, III, 724-5(1914).—Crude Ca cyanamide has come into use as raw material for the industrial production of such compds. as NH_3 , cyanides, guanidine, urea, thiourea, dicyanodiamide and veronal. Some details are given regarding the method of treatment to obtain these products. Ca cyanamide has such great reactivity that it is difficult to obtain high yields and pure products on account of the ease with which secondary reactions take place. E. J. C.

Algae ashes. C. KLINGBIEL. Biebrich. *Chem. Ztg.* 39, 121(1915).—General remarks, with analyses of 2 samples of French ashes. J. H. MOORE.

Furnace for roasting pyrites (BARTH) I.

REIMENOWSKY, E.: Erdmann-König's Grundriss der allgemeinen Warenkunde unter Berücksichtigung der Technologie und Mikroskopie. Aufl. XV. Leipzig: J. A. Barth. 954ss. 23 M.

Brit., 468, Jan. 7, 1914. NORSK HYDRO-ELEKTRISK KVAELSTOFKYLINGSKAB. Granulating calcium nitrate and other metallic salts without the formation of dust by causing them to flow in a molten state through a perforated plate, the drops so formed being hardened or solidified by causing them to move through air or other gas. The plate is disposed across a shaft or the like through which the air may be forced to reduce the velocity of the drops; in the case of an hygroscopic substance, the air may be circulated and, if desired, cooled. An inert gas may replace the air. To facilitate quick solidification, the same substance in a pulverized solid state may be added to the molten mass before it reaches the plate. Cf. C. A. 8, 216.

Brit., 1,133, Jan. 15, 1914. F. ROWLEY and SANRAINE SYNDICATE. An electric and heat insulating material is made from silk cotton, such as kapok, roa fiber, and the fibers of *Bombax malabaricum* and *Gallotropis gigantea*. The silk cotton is compressed and may be mixed with other materials or mounted upon a strengthening base, such as a slab of slate. In the latter form, it may be used in elec. switches. For waterproofing purposes, the sheets formed of the silk cotton may have a matrix or be secured by adhesive. For heat insulation, the material is placed between the double walls of a vessel.

Brit., 1,188, Jan. 16, 1914. J. ARMSTRONG. In the manuf. of fuel, ore, and like lumps by mixing the material with an agglomerant that will cake or coke under heat, the caking or coking operation is performed automatically and continuously in closed molds out of contact with air.

Brit., 1,446, Jan. 19, 1914. F. DEMOVN and E. MARIUS. Whitening or glazing corks for stoppers and the like by shaking them in a receptacle containing starch or talc powder. After removal, they are shaken in a muslin straining bag to remove any surplus material.

Brit., 1,550, Jan. 20, 1914. CHEM. FABRIK GRIESHEIM-ELEKTRON. Reduction of sulfurous acid or its salts by spongy zinc. See C. A. 9, 518. Sodium thiosulfate is obtained by passing SO_2 into a well cooled mixt. of spongy Zn and H_2O and treating the ZnS_2O_3 soln. with Na_2CO_3 .

Ger., 280,368, July 31, 1913. A. THODE & Co. Mfg. flexible plates, such as artificial leather and the like, from fibrous material, by immersing the material in an emulsion containing H_2O -sol. artesian oil (1-10% oil to 90-99% H_2O), and which may also contain glue or other binder. Animal fats (fish or whale), or oils, may be added also. The materials remain in this emulsion until impregnation is complete, whereupon they are worked in a rag engine or the like until reduced to fiber which is worked up into plates on a paper or pulp machine, and then compressed by a hydraulic press and dried. Scrap leather may be used, also vegetable fibers such as jute, rags, hemp, also cellulose, wood fiber, cork, gum, camel hair, asbestos fiber, and the like.

Ger., 281,044, Feb. 11, 1913. H. HAAKE. In the manuf. of ammonia and formic acid, compds. of the type of the ferrocyanides are decomposed with H_2O or bases at an elevated temp. *E. g.*, 135 parts $K_4Fe(CN)_6$ are heated with 260 parts H_2O in an Fe pressure vessel to about 200° . The mass is maintained at this temp. until no more increase of pressure is observed, and NH_3 and HCO_2K are obtained in the known manner. Or, 2 equivs. of $Ca(OH)_2$ are added to $K_4Fe(CN)_6$ lye (from gas purifying masses), and the whole is heated in the autoclave to $200-50^\circ$ until no more increase of pressure is observed. After recovery of the NH_3 the Ca formate is worked further in the usual manner. Or, gas-purifying mass mixed with excess lime is blown with steam, at $200-50^\circ$, until the reaction for NH_3 disappears, and the Ca formate is extd. from the residue.

Ger., 281,084, Apr. 24, 1913. E. HERMAN. In mfg. nitrogen oxides by the combustion of air with the aid of C compds., CH_4 is burned with air enriched with O in a reaction chamber communicating with a cooler for the gases of combustion, and under high pressure, in such manner that condensed H_2O cannot return into the reaction chamber. The operation is carried out either directly, with formation of flame in excess of O, or indirectly with flameless combustion with a zircon mass. While CH_4 burned alone in air enriched with O in excess, yields a N oxide product of about 1.3 vol. %, when the yield is calcd. to the whole amt. of the gases, including water vapor, the concn. of the N oxide in the gases of combustion increases materially when the CH_4 is burned, at 20-30 atm. pressure, with proportionally the same amt. of O and N, with the addition of air rich in O (50-60%) and an excess of 10-20% O, to form NO_2 readily. Since the steam condenses without more than 5-10% of the resulting N oxide combining to form HNO_3 , there is obtained without combustion under pressure, a N-concn. in the dry products of combustion of about 2 vol. %; this yields a com. HNO_3 of about 30° Bé.; with pressure combustion, a N oxide yield of 3-4 vol. % is obtained. To form 1 kg. HNO_3 (100%), not more than 2.5 cu. m. CH_4 are necessary. The granular zircon material withstands the necessary temps. without being altered in the least; also the combustion products of CH_4 have no injurious action on the zircon mass.

Ger., 281,095, Apr. 29, 1913. AKT. GES. DER CHEM. FABRIK POMMERENHOF. Obtaining ammonia, contained in gases, vapors and liquors, in the form of a highly concd. NH_4 salt soln., by means of an acid gas, especially SO_2 . In an atm. of steam the $(NH_4)_2SO_4$ seps. as a concd. aq. soln. under the influence of centrifugal force, while the dissociated salt remaining is converted into sulfate. HCl may be employed instead of SO_2 . The sulfite soln., in part oxidized to sulfate, is obtained in a soln. with 10-14% NH_3 and a sp. gr. of 1.2-2.25, continuously, through the suction app. If necessary, moisture is supplied to the gases.

Ger., 281,096, Aug. 15, 1913. C. WALDECK. Obtaining ammonia from coke breeze with the aid of steam or a mixt. of steam with other gases, at a temp. favorable to the conversion of the N in the initial material into NH_3 . The liberation of the N of the coke breeze in the form of NH_3 is possible only by processes in which the C content is at the same time decreased, *i. e.*, burned. So far all attempts to correct this condition have failed, since the NH_3 breaks up into its elements at $500-50^\circ$, while the oxidation of the C by means of the O of the air requires a higher temp. (above 700°). The coke must therefore be brought to the suitable temp. between the formation and the decomp. of the NH_3 , if the conversion of the N into NH_3 is to be approx. theoretical. To accomplish this, interior elec. resistance heating is employed.

Ger., 281,132, May 4, 1913. F. KOPP and R. GOGRO. App. for obtaining carbon dioxide from the alk. earths by igniting them on a band passing through the heating zone.

Ger., 281,133, Mar. 12, 1914. A. BERNUTAT. Sulfuric acid concentrating apparatus, wherein the acid is led through a series of chambers, counter to the hot gases.

Ger., 281,134, July 4, 1913. J. AUER. Preps. with much higher content of active O than possible heretofore (10.5%), such as pertetraboric acid or its salts, are obtained by treating $H_2B_4O_7$ with H_2O_2 or other peroxides containing active O, at temps. not above 15° , preferably below 0° . E. g., 1000 g. crystallized H_2BO_3 are converted, by ignition, into $H_2B_4O_7$. This is pulverized and the powder is placed in 14 kg. of 3% H_2O_2 , which is cooled below 0° . Also, a soln. of 350 g. Na_2O_2 in 2 kg. of H_2O cooled below 0° is prepd. Both solns. are mixed, with constant stirring and cooling. The resulting compd. is a white cryst. salt, sol. in H_2O , and yielding large quantities of active O upon boiling or when acted upon by acids. The compn. corresponds to the formula $Na_2B_4O_{11} + 6H_2O$. The active O content is, on the average, over 16%. Other pertetraborates, especially of the heavy metals, can be prepd. from these.

Ger., 281,174, Feb. 27, 1913. BADISCHE. $CaSO_4$ or gypsum can be converted into ammonium sulfate and $CaCO_3$ by means of solns. of $(NH_4)_2CO_3$. The difficulty experienced in this process is the sepn. of the fine lime slime from the $(NH_4)_2SO_4$ soln. To overcome this difficulty, immersion filters are employed, as in Au extn. The carbonate slime coats the filter with a uniformly pervious film, which remains equally effective after washing out. A small amt. of wash water only is needed.

Ger., 281,235, Feb. 11, 1913. F. HOFFMANN-LA ROCHE & Co. In evaporating and drying calcium caseinate solutions, for the purpose of obtaining a non-dielec. powder, aq., e. g., 10%, Ca caseinate solns. are conducted, drop-wise, through the drying chamber counter to a current of air and against auxiliary currents of air directed at an angle from the bottom of the chamber, to prevent deposition of the soln. on the walls of the chamber, and repeatedly in this manner through this drying chamber, until all the H_2O has been removed, whereupon the dry powder is carried out of the chamber by means of the current of air.

Ger., 281,302, Apr. 22, 1914. Addition to 276,553 (C. A. 9, 730). C. KRUG and H. BÖLLERT. Application of the principal process of waterproofing and graining artificial leather, to paper, pulp, textile materials, and like materials. The initial materials are heated *in vacuo*, satd. with resin solns., and then treated *in vacuo* with $HCHO$ vapors. The materials are claimed to be strengthened throughout, and rendered waterproof, since the $HCHO$ vapors can penetrate open pores.

Ger., 281,317, Dec. 11, 1912. J. WOLF. In mfg. ammonia from a mixt. of CO, N and H_2O , a gas mixt. rich in CO and N, such as is obtained, together with other constituents, by leading air over coke, coal, and other carboniferous material, is brought into contact, after it leaves the generator, with H_2O in a finely divided vapor form or in the liquid state, whereupon NH_3 , NH_4 salts, or derivs. and CO_2 are formed. The yield is increased by applying pressure. The temp. should remain between 300 and 450° . Instead of a mixt. of CO and N, CO alone may be employed when the N is present with the added H_2O or is mixed therewith.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLÄNINGER.

The process of gilding on glass. ANON. *Poll. Gaz.* 40, 547(1915). — The method of prepg. a glass surface in applying gold leaf is described. A formula for "sizing" is given and also the details of applying the leaf. C. S. K.

Present position of the ceramics industry in France. *Bull. soc. d'encour. ind. nat.* 122, 181-98 (1915). R. J. C.

Saggars: Past, present and future. J. P. GUY. *Pott. Gaz.* 40, 54-6 (1915).—G. describes some of the older saggars and mentions the proper kind of marl suitable for use in connection with fire clay in the manuf. of saggars. A new kind of saggarr mix containing asbestos is described as being very satisfactory and capable of withstanding severe temp. changes. C. S. K.

Nickel and cobalt colors. J. W. MELLOR. *Pott. Gaz.* 39, 679-81 (1915).—M. explains the use of the tri-axial diagram in dealing with 3 materials, such as is the case, e. g., in a study of Ni and Co colors. C. S. K.

Some casting slip troubles. J. A. AUDLEY. *Pott. Gaz.* 40, 538-41 (1915).—The trouble discussed here is the more or less dark discoloration produced at the spot where the slip, when poured in, strikes the surface of the mold. Some of the suggested causes are: properties of raw materials, comp. of the body, presence of sol. salts, etc., iron rust, condition of slip, condition of the plaster in the mold and mode of introducing the slip. The use of water-glass, instead of Na_2CO_3 , frequently helped to remedy this trouble. C. S. K.

The distribution of heat in ceramic ovens. BIGOT. *Pott. Gaz.* 40, 286-8 (1915).—B. dwells at some length on ancient firing processes, and describes briefly the design of the kilns. Attention is called to the extremely small amt. of heat used in the actual burning of the ware and the very large amt. consumed in heating the large air excess, the walls, by radiation, conduction, etc. The efficiency of the Dressler tunnel kiln is emphasized and it is stated that this is the solution of the clay-worker's fuel problem. C. S. K.

The clay trade from the British and German standpoint. W. R. ORMANBY. *Pott. Gaz.* 40, 178-82 (1915).—O. shows that the use of the "osmose" process of purifying clays electrically will make the English clays as good as the German deposits. C. S. K.

Clay and shale deposits of the Western Provinces. IV. H. RING. Canada Dept. Mines Geol. Surv., *Mem.* 65, 83 pp. (1915).—An exam. of the clay and shale deposits found in the Western Canadian Provinces from the viewpoint of their adaptability for the making of brick, tile, sewer-pipe, etc. The theory that the plasticity of clay is due to colloidal material was confirmed although there is strong evidence to show that other factors besides colloids are operative. Fifty g. samples of 4 different clays were shaken up in 1 liter of distd. water and allowed to stand. At the end of 24 hrs. but one had settled while the others had material in suspension at the end of 20 days. Pipet samples were then taken from different depths and examd. The particles in suspension in two of them could not be seen with magnification of 600 diams. while the particles in a third were visible and measured 0.002 mm. in diam. The difference in diam. suggested a possible difference in the nature of the colloidal material present; investigation showed a difference in content of carbonaceous matter. Organic matter has a greater effect on plasticity than inorganic matter, probably because it increases the viscosity of a mixt. of water and suspended clay particles and because it acts as a protective colloid and holds the clay particles in suspension. In all, 37 samples of clay are reported, including a record of their air shrinkage, fire-shrinkage, and absorption per cent. at different temps. Cf. following abstr. R. L. SIBLEY.

Clay and shale deposits of the Western Provinces. V. J. KEELER. Canada Dept. Mines Geol. Surv., *Mem.* 66, 74 pp. (1915).—The addition of about 3% of caustic lime to a clay in the raw state destroys the stickiness, reduces the plasticity, makes the wet body workable and assists in the drying. Expts. seem to show that while the

clay may be rendered workable by means of quicklime, it causes a weakening of the burned body and increases the tendency toward scumming. In working a calcareous clay, a good strong yellow color should be produced in the burned product. A pink color is an indication of underburning. Ca carbonate existing in coarse particles or pebbles in a clay is usually fatal to the permanency of the brick made from it although hard burning reduces the loss from this source. Several of the clays examd. could not be used because large cracks developed on drying. These cracks seemed to be caused by the presence of silica in a colloidal, jelly-like form. To overcome this tendency to crack during drying, several methods may be used. As much as 50% sand will usually prevent cracking although the substitution of calcined clay produces a better burned body. Pre-heating the clay in a rotary kiln to 400-500° destroys the adhesive, pasty qualities and makes it easier to work. Chemical coagulants, such as Na_2CO_3 , $\text{Ba}(\text{OH})_2$, HCl , NaCl were used, but none of the objectionable features of the clays were overcome except in the last case where the drying qualities were improved but not the working qualities. Quicklime hastens the drying and improves the working qualities but produces a white scum on the surface unless burned to a high temp. Expts. with lime upon various clays must be made before a full report of its effect can be made. Cf. preceding abstr.

R. L. SIBLEY.

Use of gas for furnace heating (BRAYSHAW) 21. Electrical pyrometry (PAUL) 1.

SEARLE, A. B.: *The Clayworker's Handbook*. 2nd ed. Philadelphia: J. B. Lippincott Co. 416 pp. \$2.00.

U. S., 1,139,637, May 18. T. M. CAVEN. Making light, porous bricks from kieselguhr by agitating it with H_2O and successively added portions of sawdust or other vegetable fibrous material, molding, drying and heating to a temp. high enough to burn out the vegetable fiber. Less H_2O is required for mixing than is necessary if all the sawdust is added at once.

U. S., 1,139,739, May 18. J. G. VANL. and J. D. CANNON. Forming abrasive wheels of carborundum by mixing it with a filler, e. g., hydrous clay, and sufficient 60° B ϕ . Na silicate soln. mixed with 5% of KMnO_4 to form a plastic mass, molding and baking. The KMnO_4 prevents defects which might be caused by formation of H in the mixt.

Brit., 1,039, Jan. 14, 1914. PERMUTIT AKT.-GES. In mfg. double silicates, melts of aluminiferous substances, SiO_2 and alkalis are lixiviated, to obtain base-exchanging substances, with H_2O to which has been added SiO_2 in a form capable of combining with alkali, e. g., amorphous SiO_2 , colloidal SiO_2 , and water-glass soln. rich in SiO_2 . Or substances capable of pptg. colloidal SiO_2 may be added to the H_2O , such as dil. acids, acid salts such as bisulfates or bisulfites, or neutral salts of strong acids such as KCl , NaCl or Na_2SO_4 . These additions prevent the extn. of SiO_2 from the melts. Cf. C. A. 9, 1235.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Combating dust in the manufacture of portland cement by means of Cottrell's electrical precipitation method. W. A. SCHMIDT. *Rev. metal.* 11, I, 1266-34(1914).—A description of the arrangement installed by the Riverside Portland Cement Company, Calif., for abating the dust nuisance. During the manuf. of cement the amt. of dust discharged from one furnace during a 24-hr. period amounted to 4-5 tons. This

ment has been very materially reduced following the introduction of the Cottrell process. Electrodes, between which a p. d. of 45,000 v. was maintained, were mounted on the summit of the chimney. The dust deposited by the process is removed mechanically and the cleaning of the electrodes is attended with little difficulty. As feldspar is utilized in the manuf. of the cement, the principal constituents of the dust are volatilized K salts, so that the process may furnish an important source of K for fertilizer manuf.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Feasibility of coal ash in various atmospheres. A. C. FIELDNER AND A. E. HALL. *J. Ind. Eng. Chem.* 7, 399-406, 474-81 (1915).—Results on 63 samples of coal ash fused

in 8 furnaces with atmospheres of varying degrees of oxidation and reduction. Ash ground to an impalpable powder tended to soften 6-40° lower than 100-mesh ash. Vertical cones gave the most concordant results. Slower rates of heating gave lower softening points. The most important factor is the atmosphere. ISADOR MILLER.

Results of the investigation of five lignite samples from Alberta. B. F. HAANEL AND JOHN BLIZARD. *Summary Rept., Mines Branch, Canada Dept. Mines* 1913, 109-32.—Results of gas producer tests made with various Canadian lignites to det. their adaptability for use as gas fuel were favorable. With a Westinghouse double zone producer no serious difficulties of operation were encountered, the gas was sufficiently clean to be used in a gas engine, and little or no clinkering was noticed. The efficiencies (ratios of heat of gas formed to that of coal charged) varied with the different lignites from 61% to 72%. Certain lignites have a N content sufficiently high to make the NH₃ recovery profitable. H. L. OLIN.

Canada's peat bogs. ANON. *J. Can. Peat Soc.; Chem. Trade J.* 61, 440(1915).—Their possibilities for development as a result of the European war are discussed. E. J. C.

The use of gas for furnace heating. S. N. BRAYSHAW. *Pott. Gas.* 40, 442-3 (1915).—The main difficulty in burning gas in the ordinary way is to get enough air, 5½ vols. of air being required per 1 vol. of gas. Several types of burners, designed to overcome this difficulty, are described. C. S. K.

Burning blast furnace gas. K. HUESSENER. *Iron Age* 95, 612-3(1915).—Description of the Bradshaw-Huessener gas burner with gas ejector that automatically controls the amt. of air according to the wt. of the gas. H. V. MAIN.

Purifying producer gas. A. J. WALLACE. *Iron Age* 95, 896-7(1915); *Chem. Eng.* 21, 217-8(1915).—A mixt. of shavings and oxidized iron, 22-4 lbs. per bu., is used to remove H₂S. Rotation of purifiers, 4 to a set, permits the regeneration of the oxides by the O from leaks. H. V. MAIN.

Regenerators and recuperators. M. STEIN. *Rev. metal.* 11, I, 1191-6(1914).—A general discussion of the comparative merits of the 2 types of furnaces. L. T. F.

Composition of gas in relation to its calorific value. ANON. *Gas World* 62, 563-4.—Discussion of calorific value, "combustive power" and thermic value with tables containing a list of the principal heat-giving constituents of coal gas and showing their relative power and values. M. L. TROWERIDGE.

Gasholder without water of the *Maschinenfabrik Augsburg-Nürnberg*. ANON. *J. Gasbel.* 58, 13-4(1915).—The walls are built full height and smooth inside. The top slides up and down inside this cylinder, and is provided with an annular space between its edge and the walls for the sealing liquid. The bottom of this space is closed by a ring which slides on the walls and allows only slight leakage. The leakage collects in an annular trough at the bottom of the holder and is pumped to a container at the top which feeds the seal. As there is no loss of liquid, any material may be used for the seal. Gas tar does not freeze, is always available, leaks only slowly through the sliding contact, and protects the inside of the walls from corrosion. For a 25,000 cu. m. holder, 0.1 h. p. is needed. This represents 3% of the cost of heating H₂O in an ordinary holder of the same capacity. Advantages claimed are low first cost, low operating cost, absence of H₂O reservoir and of heating, certainty of operation, simplicity of repainting (none needed inside), accessibility of all working parts during operation. W. L. BADGER.

Variation in composition of natural gas from different sands in the same field. G. A. BURRELL AND G. G. OBERFELL. *J. Ind. Eng. Chem.* 7, 419(1915).—Invariably

the gas from the shallower sand was found to contain less of the heavier paraffin hydrocarbons than that from the deeper sands. IRADOR MILLER.

The German gas industry in relation to the war. DEUT. CONTINENTAL-GAS-GESELL. Dessau. *Chem. Ztg.* 39, 81-2(1915). J. H. MOORE.

The fractional collection of crude tar. GEO. T. PURVES. *J. Soc. Chem. Ind.* 34, 339-39(1915); *J. Gas Lighting* 130, 200-2(1915).—P. describes a device for condensing tars by fractional pptn. The crude gas from the main is scrubbed with a screen of anthracene oil to remove the tar fog containing free C and after partial cooling is again scrubbed to remove anthracene oil. The process is repeated with successive temp. lowerings and scrubblings in such a way that the tar may leave contact with the gas only at a temp. at which it cannot dissolve the next lighter fraction. This method obviates the necessity for tar distg. with attendant cracking losses. Benzene and toluene may be left in the gas to increase the candle power or they may be removed by a simple washing process. H. L. OLIN.

Commercial and economic phases of the coal-tar situation. HORACE C. PORTER. Bur. of Mines, *Tech. Paper* No. 89, 18-9(1915). E. J. C.

Coal-tar products, and the possibility of increasing their manufacture in the United States. HORACE C. PORTER. Bur. of Mines, *Tech. Paper* No. 89, 5-15(1915).—This paper points out the present opportunity for developing in the U. S. some industries hitherto comparatively neglected. P. discusses with data the supply of coal suitable for by-products manuf., the production and disposal of coal tar and of benzole, and coal-tar products, such as creosote oil, light oil, benzole, solvent naphtha, heavy tars, pitch products, phenol, dyestuffs, drugs, photographic developers, etc. E. J. C.

Discolored sulfate of ammonia. ANON. *Gas World* 62, *Coking and By-Product Sect.* 18-9.—The discolorations most frequently experienced are grey, brown, yellow, blue and red. A discussion is given of the conditions under which they occur and their prevention. M. L. TROWBRIDGE.

Nitrogen determination in coke. B. M. MARGOSCHES. Brunn. *Chem. Ztg.* 39, 167-8(1915).—General remarks on the Kjeldahl method and modifications. J. H. MOORE.

Much of this waste contains considerable amts. of starch granules, albumin, and the like, and the pine twigs contain, in addition, large amts. of resin, and, in fact, a mixt. of true resin, ethereal oils, and hydrocarbons. The treatment consists in comminuting the material, mixing it with ground charcoal, and briquetting the mass. The briquets are especially suitable for glass and porcelain works. Cf. C. A. 8, 2938.

Ger., 281,275, July 3, 1913. O. BUSSE. In a heating and combustion furnace with muffle, the air or gas content of the muffle is circulated continuously by means of a fan, in order to maintain a uniform temp. within the muffle and thereby effect more rapid heating of the charge.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Gasoline from "synthetic" crude oil. WALTER O. SNELLING. *Bull. Am. Inst. Mining Eng.* 1915, 695-704.—S. describes lab. methods by which he has produced gasoline from heavy oils and discusses their industrial application as well as their relation to the problem of the genesis of petroleum. In a typical test, 300 cc. of a solid white paraffin, m. 50° , sp. gr. 0.925, was used. This was sealed in a vessel of 1100 cc. capacity and heated until a pressure of 800 lbs. was indicated, then cooled. The pressure of the residual gas was 130 lbs. The product was a heavy liquid resembling Penn. crude oil, dark green by reflected light, dark red-brown by transmitted light. Its vol. was 305 cc., sp. gr. 0.770 and the gasoline yield on distg. to 150° was 48 cc., or 16%. By removing the gasoline and repeating the process he has obtained from paraffin 70% of water white gasoline, the remaining 30% representing the gas formed, and some free C. Cf. C. A. 9, 1388. H. L. OLIN.

The cracking of oils. E. I. DYER. *Mining Sci. Press* 110, 717(1915).—A brief discussion of the cracking of oils in "concentrates." It is stated that "the com. objection to the cracking processes is that the distillate evolved usually contains olefins and similar complicated members of the aromatic and other series which impart an undesirable color and odor to the product, so that excessive treatment is necessary to get a merchantable material. Such treatment usually results in almost total loss of everything except the paraffin series." It is concluded that in most cases it is usually better to adhere to the ordinary distn. methods. F. W. SMITHER.

The time factor in making oil gas. M. C. WHITAKER AND C. M. ALEXANDER. *J. Ind. Eng. Chem.* 7, 484-95(1915).—The compositions of the products obtained in making oil gas vary with the rate of oil feed and hence with the time factor. This variable is as important as the other three, temp., pressure and concn. Only by proper adjustment of all four can max. and min. % of the various constituents in the products formed by the decompn. of petroleum and petroleum distillates by heat be obtained.

ISADOR MILLER.

Naphthenic acids of high molecular weight in Baku petroleum. E. PYHALA. *Baku. Z. angew. Chem.* 27, I, 407(1914); cf. *C. A.* 8, 2800, 3361.—The acids in the waste lyes from the refining of Baku machine oils were liberated with dil. H_2SO_4 , washed, dried, and distd. *in vacuo*. The distillate was extd. with alc. KOH, the alc. evapd. off and recovered and the naphthenic acids liberated from the soap by dil. H_2SO_4 , washed and dried. The product (naphthenic acids) was a light yellow, very viscous, almost odorless oil with acid no. = 100. When dissolved in ether, shaken with concd. HCl, washed with H_2O till free of acidity, filtered, and the solvent evapd., it left a residue of $d_{16}^{19.8} = 0.9470$, acid no. = 168.7, I no. = 2.54 (Hübl-Waller). On fractional distn. at atm. pressure 2 fractions were obtained: (a) 310-320° about 13%; d. detn. not made; acid no. 180.4; identified as eicosan-naphthenic acid ($C_{19}H_{37}COOH$); (b) 340°, about 63%; $d_{16}^{21} = 0.9400$; acid no. 147.6; identified as pentacosan-naphthenic acid ($C_{24}H_{47}COOH$). Both fractions had the typical naphthenic odor; it was hardly perceptible when cold.

Brit., 1,145, Jan. 15, 1914. E. OMAN. Utilizing sulfite liquor for the digestion of 3 or 4 charges of wood, especially for the production of half-cellulose, by treating it after each digestion with lime, or magnesia, or alkali, and SO_2 . Part of the waste liquor is used for the recovery of organic and inorganic substances, either by fermenting and distg. off the alc. and then concg., or by removing part or the whole of the non-fermentable substances and then fermenting and distg. For digestion, a suitable quantity of washing H_2O , with or without other pure H_2O , may be added.

Brit., 1,156, Jan. 15, 1914. AET.-GES. FÜR ANILIN FABRIKATION. Addition to 10,706, 1912 (C. A. 7, 3414). The process of prepg. cellulose esters described in the principal patent is modified by subjecting to the usual methods of esterification the cellulose deriv. obtained by the action on cellulose of more or less concd. HNO_3 . The latter product is stated to have the same properties distinctive from ordinary nitrocellulose as had the parent material described in the principal patent, and, in an example, is prepd. by treating cotton with from 10 to 30 times its wt. of 68-70% HNO_3 . The ester may be hydrolyzed, as by treatment with an acid.

Brit., 1,223; Jan. 16. 1914, A. R. VON S. SZOLATSKY. A celluloid substitute is made by dissolving 200 g. of glue or gelatin in H_2O and mixing it with 30 g. each of casein and Na_2SiO_3 . The mixt. is poured upon glass sheets, dried, and hardened by means of alum, tannin, etc.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

C. E. Bichel. W. KÖNING. *Z. ges. Schiess-Sprengstoffw.* 10, 73-4(1915).—An obituary. C. G. S.

Influence of temperature and pressure on the explosibility of methane-air mixtures. G. A. BURRELL AND I. W. ROBERTSON. *J. Ind. Eng. Chem.* 7, 417-9(1915).—With an initial temp. of 500° the low limit of complete propagation of flame is 3.75-4.00% CH_4 . Lowering the temp. raises the low limit, the latter being 5.5% CH_4 at ordinary temp. ISADOR MILLER.

Inflammable limits of mixtures of gasoline vapor and air. G. A. BURRELL AND H. T. BOYD. *J. Ind. Eng. Chem.* 7, 414-7(1915).—The lower limit of complete inflammation has a value between 1.9 and 2.0% gasoline vapor. The upper limit is 5.2, 5.3%. These figures hold when ignition takes place from the top. Igniting from the bottom, the figures are 1.5-1.6%, and 6.0-6.4%, resp. Increasing the initial temp. before ignition decreases the low limit. ISADOR MILLER.

Coal-tar products used in explosives. C. G. STORM. Dept. Interior, Bur. Mines, *Tech. Paper* 89, 16-7(1915).—A brief review of the uses of the aromatic nitro-substitution compds. as explosives or as constituents of explosive mixts.; nitrobenzenes, nitrotoluenes, nitromaphthalenes, nitrophenols and their various derivs. are included. These compds. and their derivs. find use as bursting charges for explosive projectiles, torpedoes and mines, or in detonators and primers, as ingredients of low-freezing dynamites, as colloidizing or gelatinizing agents in plastic explosives or smokeless powders, as stabilizers in nitrocellulose smokeless powders, as sensitizers in NH_4NO_3 explosives, etc. C. G. STORM.

Fuses and igniters. A. OELKER. *Z. ges. Schiess-Sprengstoffw.* 10, 66-8, 78-9(1915).—A list of 26 U. S. and 3 British patents relating to fuses and means of ignition of fuses, giving brief specifications. C. G. STORM.

Sensitiveness of dynamite. ANON. *Eng. Mining J.* 99, 820(1915).—The test is made by rolling the two halves of a stick in a sheet of letter paper, varying the distance sepg. them from 12 to 2 inches. At the latter distance the detonation of one-half detonated the second half, but it failed to do so at greater distances. C. E. MUNROE.

Comparative strength of detonators. LEB. REIFSNIEDER. *Eng. Mining J.* 99, 818(1915).—Detonators were tested with 40 and 60% semi-gelatin dynamite, using "influence" method on steel plates. 60% grade was detonated at a distance of 52 inches with No. 8 and at but 26 inches with No. 6 detonator. A large number of tests were made. CHARLES E. MUNROE.

Vacuum-drying apparatus in the explosives industry. E. SCHWEIZER. *Z. ges. Schiess-Sprengstoffw.* 10, 38-40, 53-5(1915).—The advantages to be gained by vacuum drying as compared with drying in a current of air by the usual methods are: (1) greater rapidity of drying, (2) economy of heat, (3) increased safety. In drying such explosives as nitrocellulose, smokeless powder, fulminate of mercury, and detonating compns., vacuum drying insures greater safety because the b. p. of the liquid to be removed is lower at the reduced pressure, and because the effect of the vacuum is to diminish the readiness with which explosions may be propagated. It has long been known

that ordinary gunpowder is ignited imperfectly, if at all, by means of an incandescent wire in rarefied air, and under the same conditions guncotton burns very slowly, while even mercury fulminate does not propagate explosion readily. Tests made in the Royal Prussian works at Spandau showed that large quantities of fulminate could be exploded in a properly constructed vacuum drier without material damage to the app. This special type of drier (described in detail) has automatically opening vents for relieving sudden pressure in case of explosion. Drying is hastened by circulation of warm water through the hollow shelves. Black powder is dried in 1 hr., mercury fulminate in $\frac{3}{4}$ hr. with a vacuum of at least 700 mm. Another type of drier is installed at the Spandau works for rapid drying of smokeless powder. At a temp. of about 30°, 95-97% of the original solvent is recovered by means of condensers, and rapid drying of the powder is effected.

C. G. STORM.

Accidents in the explosives industry. BADERMANN. *Z. ges. Schiess-Sprengstoffw.* 10, 57-8(1915).—Includes short accounts of 7 accidents in explosives factories. Of especial interest is an account of an explosion of 100 kg. of trinitrotoluene at the govt. factory at Magdeburg. The material was being washed and exploded from unknown cause, killing 4 workmen and wrecking the wash- and dry-houses. C. G. STORM.

Explosives in Greece. A. LOGOTHETIS. *Z. ges. Schiess-Sprengstoffw.* 10, 52-3(1915).—A brief review of the explosives industry in Greece. Raw materials except HNO_3 and H_2SO_4 are imported from Germany and Austria. A system of govt. inspection controls the manuf. and use of explosives.

C. G. STORM.

Tungsten projectiles (VASSELIN) 9.

U. S., 1,141,009, May 25. C. SECHANANDOAH. An explosive for blasting is formed by moistening a mixt. of alum 1 and sugar 16 parts with coffee ext. and then adding MeOH and boiling the mixt. until moisture is eliminated and a solid mass remains. The latter is mixed with about $1\frac{1}{7}$ times its wt. of KClO_4 whenever desired to complete the explosive., *e. g.*, just prior to the time of use.

Brit., 1,283, Jan. 16, 1914. ACCUMULATOREN-FABRIK AKT.-GES. In a device for detecting the presence of methane or other inflammable gases in air by means of glowing catalytic conductors heated from an exterior source, a number of heated conductors are employed, so that the number which become luminous serve as an indication of the quantity of inflammable gas present.

Brit., 1,493, Jan. 20, 1914. R. CREMER. In suppressing explosions in mines by means of stone or other dust, the dust is pressed together to form self-sustaining walls, banks, blocks, slabs, columns, etc., which are placed at the sides of the roadways and in the working places and are adapted to be broken up and scattered by the force of an explosion. The dust may be mixed with a binding material, such as cement, concrete, tar, sizing, clay, etc., or the compressed walls, blocks, etc., may have their surfaces treated with such material. The dust may also be enclosed in millboard, wicker-work, expanded metal, wire gauze, etc., the interstices of which are closed by plastering over with cement, concrete, lime, plaster, clay, etc., or by a lining of fabric, preferably in loose sheets.

a violet powder sol. in H₂O to a violet soln., dyeing wool in an acid bath violet fast to alkalis and only slightly altered after chroming; made by boiling 1-amino-2-ethoxy-4-bromo- (or chloro)anthraquinone with NaOAc and *p*-toluidine and sulfonating with fuming H₂SO₄.

U. S., 1,139,603, May 18. H. P. VEST. "Wax" for waterproofing thread, composed of gasoline 62.5%, rosin 31.25% and pine tar 6.25%.

U. S., 1,140,296, May 18. M. A. ADAM and W. J. FERNIE. Retting flax straw by passing H₂O at a temp. of about 37° downward through straw placed vertically, for about 8 hrs. and then lowering the temp. of the H₂O to 20-5° for the remainder of the time required to complete the retting.

U. S., 1,140,745, May 25. B. JÄCKEL. Sulfur dyes obtained by heating ethylaniline 17.6 and benzidine 27 parts, with S 80 parts, extg. with alkali and pptg. with HCl. The dye is a yellow powder, insol. in H₂O, sol. in concd. H₂SO₄ with a yellowish brown color and produces greenish yellow effects on unmordanted cotton. Ethyl- α - and β -naphthylamine, ethylxylidine, ethyltoluidine, and ethylbenzidine yield similar dyes.

U. S., 1,140,747, May 25. M. KAHN and A. OSSENBECK. 2,3-Naphthoic acid derivative of the formula

a grayish yellow powder sol. in hot Na_2CO_3 soln., giving a fast scarlet-red color on unmordanted cotton when developed with diazotized *p*-nitroaniline.

Brit., 745, Jan. 10, 1914. M. A. ADAM, W. J. FERNIE and FIBER CORPORATION. Bacterial fermentation in the retting of flax, etc., is accelerated by carrying out the operation in 2 stages, the 1st at a temp. of about 37° , occupying from 8 to 24 hrs., and the remainder at a temp. of from 20 to 25° , which is not substantially higher than that which prevails under normal conditions when retting in running streams. The whole operation takes about 2.5 days and is carried out in an app. such as described in 11,384, 1912 (C. A. 8, 2124).

Brit., 802, Jan. 12, 1914. J. L. JARDINE and T. A. NELSON. Preparing vegetable textile fibers for bleaching by treating the material in a digester with a soln. of $\text{Mg}(\text{HSO}_3)_2$ or NaHSO_3 and completely removing from the liquid in the digester the gases liberated in the course of cooking. Bisulfites of other bases which have sol. sulfites may be used. The digestion is carried out in a closed vessel with an acid-proof lining, under pressure, the heating being preferably by means of coils or a jacket, or by the application of direct steam. The treatment removes the lignified encrustations as well as the pectose and gummy ingredients, without materially affecting the fiber, even jute and hemp only requiring 1 treatment to render them easily bleachable. The proportions of the base and available or free SO_2 depend upon the duration and the temp. of the cooking, the chem. characteristics of the fiber treated, and also its physical condition. It is essential to provide for the free escape of the liberated SO_2 . Examples are given for the treatment of jute, as raw fiber or Hessian cloth, and also of woven hemp.

Ger., 278,509, May 10, 1913. CASSELLA & Co. Mfg. basic dyes by treating the dye of 269,802 (C. A. 8, 2260) with alkalis, reducing in acid soln. the resulting leuco compds., and allowing the resulting reaction liquids to stand for a long time, or heating them.

Ger., 278,613, Nov. 11, 1913. J. R. GRIGY A.-G. Mfg. mordanting monoazo dyes by heating the azo dyes, from diazotized *o*-chloro-*m*-aminobenzoic acid and salicylic acid, *o*-, *m*-, or *p*-cresotinic acid, with alk. agents, to a high temp.

Ger., 278,871, 278,872, Jan. 8, 10, 1913. CHEM. FABRIK GRIESHEIM-ELEKTRON. Yellow cotton dyes. See Brit., 17,878, 1913 (C. A. 8, 2625).

Ger., 280,713, Aug. 16, 1913. W. FRAENKEL. Isolating the selenium dye corresponding to methylene blue by allowing H_2Se or like compd. yielding Se, to act upon *p*-phenylenediamine or the like, and oxidizing the resulting compd., then shaking the resulting reaction mixt. with phenol. The resulting soln. is shaken with aq. HCl and a H_2O -insol. solvent for the phenol, such as ether, CCl_4 , or the like, whereupon the dye goes into soln. as the chloride.

Ger., 280,839, Jan. 30, 1913. M. KARDOS. Mfg. anthracene derivatives by treating aceanthrenequinone or its halogen substitution products with NH_2OH or substances splitting off NH_2OH . Cf. C. A. 8, 3242.

Ger., 281,010, July 1, 1913. AKT.-GES. FÜR ANILIN-FABRIKATION. Mfg. amino-anthraquinone derivatives by acting with phosgene on 3-aminobenzoyl-*o*-benzoic acid, its homologs or substitution products, and treating the resulting urea, with heating, with concd. or fuming H_2SO_4 .

26. PAINTS, VARNISHES AND RESINS.

A. H. SARIN.

Miscellaneous paints used in machine shops. E. H. FISH. *Am. Machin.* 42, 941(1915).—A review.
C. G. F.

Paints to prevent electrolysis in concrete structures. H. A. GARDNER. *J. Ind. Eng. Chem.* 7, 504-10(1915); *J. Frank. Inst.* 179, 313-36(1915).—Results with 27 paints are given. G. concludes that the vehicle should contain boiled or bodied products which dry to fairly satd. films, oils which dry by semi-polymerization rather than oxidation and which give a flat surface. Pigments should be coarse, inert and nonconductors of electricity. They should be either basic or of the chromate type. The painted metal should be "sanded."

The residue sep'd. during the purification process of making soapmaker's spent lyes suitable for the prepn. of glycerol is used as a base or body for printing-inks or paints. The residue is neutralized, if acid, and is mixed with pigment or color, and with oil, varnish, etc. If the residue is of insufficient body, it is mixed with BaSO₄ or CaSO₄, kaolin, kieselguhr, chalk, or the like.

Brit., 591, Jan. 8, 1914. WICKTÜLER-KÜPPER-BRAUEREI AKT.-GES. The lacquer on the inside of metal vessels such as beer casks is burnt on by supplying hot compressed air. Cf. C. A. 8, 2466, 3355, 3356.

Brit., 1,016, Jan. 14, 1914. L. PETERSEN-HVIID. A casein product, which, when dry, is easily powdered and readily sol. in alkalis, is obtained by mixing wet curd or milk with infusorial earth, and drying; the product is intended for use as a binding medium for colors. Cf. C. A. 9, 1134.

Ger., 280,595, Jan. 25, 1913. BADISCHE. Mfg. resin-like products by treating compds. of the type of the benzylhalides of the general formula R.CH₂.X (R = an aromatic residue, X = halogen) with metal halides in the absence of diluents. Cf. C. A. 9, 1399.

Ger., 280,648, Aug. 21, 1913. H. KÜHL. Mfg. soluble condensation products by heating casein and cresol, with HCHO, in the autoclave, at 3-5 atm. pressure. Resinous products result which have a wide tech. application. Casein and cresol form a comp'd. sol. in an excess of cresol. This soln. is heated with 40-50% by wt. of a 40% HCHO soln. in the autoclave, especially with the addition of small amts. of potash, under a steam pressure of 3-5 atm., according as varnish products or tough resin products are to be obtained. To prep. the soln. of casein-cresol in cresol, the granular crude casein is left to soften with twice its wt. of crude cresol poured over it. The uniformly softened product is employed directly, or after being mixed with a suitable amt. of cresol, according as a product rich in casein is desired, or otherwise. The granular crude casein may be left in linoleic acid for 24 hrs., heated for a short time, cooled and poured, and then allowed to soften with cresol. The product is gelatinous. If finely pulverized crude casein is used as the initial material, preliminary softening or soln. is unnecessary. The casein acts, in the 1st place, as contact and condensation agent, and in the 2nd place as a filler, which yields alc.-sol. products. E. g., granular crude casein 250 g. is

softened in 500 g. cresol to a uniform mass, then worked up with 400 g. HCHO to a homogeneous mixt., and this is heated in the autoclave up to 3' atm. This pressure is maintained for about 10 min., the heating is discontinued, and the mass is allowed to cool to the temp. of the normal pressure. The product may be worked up at once with alc. to a varnish.

Ger., 281,265, Apr. 22, 1913. ZAPON-LACK-GES. M. B. H. Mfg. varnishes from cellulose derivatives by dissolving cellulose derivs. in MeOH, acetone oil, ketones, or the like, after 1st adding polymerization products of cumarone or indene or both these, dissolved in C_6H_6 , alc., or like solvent. The so-called cumarone resin, obtained in the purification of benzene hydrocarbons and consisting in the main of a mixt. of polymerization products of cumarone and of indene, is preferred. The resulting varnish is oily, lustrous, dries uniformly, is very elastic, and is stable in air and light. The amyl preps., heretofore used, are unnecessary. E. g., cumarone resin 10 g. is dissolved in 50 g. C_6H_6 and added to a liquid consisting of a soln. of 30 g. collodion in 5 g. acetone oil, 100 g. alc., and 100 g. ketones. The resulting mass is dild. with 300 g. alc., 300 g. benzene, and 100 g. MeOH, or 10 g. cumarone resin is dissolved in a mixt. of 25 g. fusel oil and 25 g. tetrachloroethane. This soln. is added to a mixt. of 600 g. acetone and 300 g. MeOH, and then 40 g. acetylcellulose are dissolved in this liquid.

Ger., 281,373, Nov. 26, 1912. CHEM. FABRIK GRISBACH-ELEKTRO. In mfg. zapon varnishes or similar solns. of nitrocellulose, celluloid, or other cellulose esters, amyl acetate may be replaced by the much cheaper ethylidene compds. of aliphatic acids. The cellulose esters are simply dissolved in the ethylidene esters. The products are neutral, colorless, and almost odorless. The solvent evaps. rapidly, leaving the ester as an elastic adherent coat. E. g., nitrocellulose 4 is dissolved in ethylidene acetate 100 parts. The resulting soln. is ready for use as a varnish. Or, nitrocellulose 1 and camphor 1 are dissolved in ethylidene diacetate 50 parts. The soln. may be used as zapon varnish. The ethylidene esters of the aliphatic acids are made in the known manner from AcH and acid anhydrides. They may also be obtained from C_2H_2 and the corresponding acids.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Fat analysis and fat chemistry in 1914. W. FAHRION. *Z. angew. Chem.* 28, I, 161-70, 183-92(1915). E. H.

Proposed uniformity in methods of fat analysis. W. FAHRION. *Collegium* 1914, 599; *J. Am. Leather Chem. Assoc.* 10, 7-18(1915).—Report of a collaborative study by the Internatl. Assoc. of Leather Trade Chemists. Materials studied: German cod-liver oil, Newfoundland cod oil, whale oil, herring oil, Spanish sardine oil, Japanese train oil, linseed oil, neatsfoot oil, and sod oil (degras). *Acid value*: The differences are very considerable. The titrations may be carried out in the cold by using instead of alc. a mixt. of alc. and petroleum ether or alc. and ether. It is concluded that no important purpose is subserved by an attempt to make comparative exams. of the acid value of marine oils, since their content of free fatty acids rises on standing. It is recommended to use at least 5 g. of substance, or in the case of high acid values even more, and that the alkali be 0.2 or 0.5 *N*. If 0.1 *N* alkali is used, and the acid value is high, the alc. of the soln. is seriously dild. by the titration. The H_2O must not exceed 50% on account of the danger of dissociation of the soaps. *Saponification value*: The usual method was prescribed with a statement by each observer of the concn. of alkali and acid used and time of boiling in sapon. The agreement is not close enough,

probably due in part to the ease with which marine oils change in comp. It is recommended that both in the case of linseed oil and of the marine oils the following points be observed: at least 3 g. of oil should be taken; the alkali should contain as little H_2O as possible, at most under 10% (it is best to dissolve the KOH directly in 96% alc., or a 2 *N* alc. soln. containing 10 or 15% of H_2O may be dild. with 3 or 4 times its vol. of 96% or of abs. alc.); 2 hrs. or even $\frac{1}{2}$ hr. is much too long to boil true oils or fats (when sapon. is complete the fat goes into clear transparent soln., and if the soln. is then boiled about 5 min., there will be no unsaponified fat remaining); in titrating back the H_2O content of the soln. must not exceed 50%. *Iodine value:* The differences among the Hübl values are very great (up to 26), but the results by the Wijs process are very concordant. It is recommended to abandon the Hübl method and use the Wijs. The values by the Hanus method fell between those given by the other 2 methods. *Unsaponifiable:* The Hömig-Spitz method was indicated. The agreement among the collaborators leaves much to be desired. The differences are doubtless due to the variations in the method made by the collaborators. F. washes the soln. of soap in petroleum ether with 50% alc. to avoid any dissociation. Unsaponifiable matter from fish oils should not be dried above 100°. One collaborator used the Bömer method (without purifying the unsapon.) obtaining in most cases higher results. F. doubts if the Bömer method, even with the purification of the unsaponifiable, would give results higher than the Hömig-Spitz method. The latter is the most convenient. *Degras analysis:* Five collaborators reported the following detns.: H_2O , ash, unsaponifiable, fatty acids, hydroxy acids, H_2O -sol. hydroxy acids, acid no., sapon. no., no. by Hübl and Wijs. Methods used are mainly those of F. (cf. *C. A.* 5, 2578). Results show good concordance. The method for detg. H_2O by mixing 5 g. with 5 g. of glass and heating to const. wt. in water-oven required 47 hours. Methods for H_2O using alc. or acetone and evapg. required about 19 hrs. F.'s method (boiling H_2O off directly) may be executed in 15 min.

F. W. SMITHER.

Constituents of animal fats. J. KLIMONT and K. MAYER. *Monatsh.* 36, 281-8 (1915); cf. *C. A.* 9, 727.—The isolation of margaric acid from horse fat led K. and M. to suspect that the eutectic mixt. of palmitic and stearic acids obtained from goose fat might contain margaric acid. This mixt. has been sepd. into margaric acid, m. 57.5-58°, and palmitic acid, m. 60-61°. By the elaidin test oleic acid was shown to be present. A fraction, m. 60.5°, was obtained by repeatedly crystg. from Et_2O ; it may be dipalmitomargarin.

C. J. WHEAT.

Analysis of Turkey red oils. W. HERBIG. *Seifensieder-Ztg.* 42, 164-5, 186-7 (1915); cf. *C. A.* 8, 2809.—H. has sought to det. whether or not the neutral fat in sulfonated oils consists of pure glycerides and to this end com. products were analyzed for glycerol and neutral fat. It was concluded that besides glycerides there are "glycerol-free" substances present. The ordinary method for the detn. of SO_2 in these products is not applicable in the newer preps. of this kind. In these cases benzene or xylene should be used instead of ether for dissolving the oil prior to shaking out the SO_2 with NaCl soln.

E. SCHERUBEL.

Constitution of soap solutions. H. PICK. *Seifenfabr.* 35, 255-7, 279-81, 301-3, 323-5 (1915).—The cond. of the K salts of individual fatty acids containing 6 to 18 C atoms was detd. The solns. were prepd. by dissolving the fatty acid in KOH in Ag flasks without access of CO_2 from the air. The detns. were made at 90° and the sp. gr. of the solns. detd. with a pycnometer. A table is given showing the cond. of K palmitate, also other tables by other authors. A 0.5 *N* solution of K palmitate at 90° is clear, a *N* soln. coagulates between 60 to 70°, while 0.01 and 0.02 *N* solns. are weakly opalescent and give a small ppt. Normal K stearate at 90° is clear and colorless but 0.05 *N* is turbid and gives a ppt. equal to $\frac{1}{2}$ of total vol. K myristate

and laurate form clear solns. with some pptn. The caprate, caprylate and caproate all give small ppts. As regards washing, the palmitate and myristate of K make ideal soaps for the hands; the stearate is less satisfactory. The Na salts are not usable. K caproate in concd. soln. is a good soap but the caprylate is better; the caprate is the only one of the series which gives a typical lather. The conds. of the K and Na salts are similar. There are 22 tables showing conds. and hydrolysis of various fatty acid salts with comments for each. E. S.

Transparent glycerol soaps without castor oil. ANON. *Seifensieder-Ztg.* 42, 185-6(1915).—Three formulas are given as follows: (1) 38 kg. tallow, 10 kg. olive oil, 10 kg. coconut oil, 31 kg. NaOH (37°), 3 kg. KOH (37°), 14 kg. H₂O, 33 kg. glycerol (28°) and 26 kg. alc. The fat is heated to 80° and the glycerol, KOH, NaOH and 1/2 the water added in order given. The alc. is added after sapon. is completed. (2) 40 kg. tallow, 5 kg. peanut oil, 45 kg. coconut, 40 kg. NaOH (38°), 9 kg. sugar dissolved in 14 kg. water, 40 kg. alc. (3) In Germany where no neutral fat may be used, a first class transparent soap cannot be made, but a transparent war soap is made from 36 kg. coconut oil fatty acids, 35 kg. peanut oil fatty acids, 28 kg. tallow fatty acids, 50 kg. NaOH (38°), 8 kg. KOH (38°), 30 kg. sugar in 40 kg. water, 8 kg. Na₂CO₃, 2 kg. KNO₃, 10 kg. of filler made from 80 kg. water, 20 kg. sugar, 11 kg. K₂CO₃ and 11 kg. salt. E. SCHERUBEL.

Use of sugar in soap manufacture. F. GOLDSCHMIDT. *Seifenfabr.* 35, 348-9 (1915).—Breymann in an article in the *Berliner Tageblatt* calls attention to the use of sugar in soap which has been recently patented. Besides its use as a filler it can be used as a substitute for fat, for it combines with alkali and the resulting compd. has deterative properties. It is said that the color of colored goods is not affected by alk. soap in the presence of this sugar compd. and also that such soap is well adapted for use with sea water. E. SCHERUBEL.

Soft soaps. L. B. *Seifensieder-Ztg.* 42, 163-4(1915).—As a substitute for potato flour, which was extensively used as a filler for this class of soap, moss is now being used. It is prepd. as follows: 1000 kg. H₂O, 60 kg. moss, 30 kg. KOH (50°) and 55 kg. K₂CO₃ are boiled for 2 hrs., and the soln. filtered and added to the soap. E. SCHERUBEL.

Colgates shaving soap. J. DAVIDSOHN. *Seifenfabr.* 35, 321-3(1915).—The analysis is as follows: H₂O 6.40, combined K₂O 9.39, combined Na₂O 3.27, fatty anhydrides 78.36, glycerol 3.70, soap 91.02%, R. M. no. of fatty acids 0.6, I no. 7.5, neutn. no. 206, m. p. of fatty acids 53°. From this it follows that the fat base of this soap is stearic acid. E. SCHERUBEL.

Oil from Manihot seeds (FRANK) 30. Oil from nuts of *Canarium polyphyllum* (WAGNER) 12. Fats (MAIN) 18.

Brit., 1,410, Jan. 19, 1914. A. H. CHARLTON. In impregnating or saturating oils or fats with gases, e. g., hydrogenating oils, a rotary drum is used, without stuffing boxes, and heated by a jacket to which steam, which may be satd., is supplied through a passage in 1 trunnion, passing out through the other trunnion.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Progress of beet-sugar manufacture in 1914. EDMUND O. VON LIFFMANN. *Chem. Ztg.* 39, 85-7(1915). J. H. MOORE.

The (French) sugar industry and the war of 1914. GEORGES DUREAU. *Bull. soc. d'encour. ind. nat.* 122, 290-306(1915). E. J. C.

The purity of the sirup adhering to raw sugar. A. HERZFELD. *Z. Ver. Zucker-ind.* 65, 1-10(1915).—Fifty-eight samples of raw sugar were tested for crystal content by H.'s method (cf. C. A. 6, 1548) and the purity of the sirup calcd. from these results. In 41 out of the 58 cases the actual factory rendement was greater than the crystal content, the difference ranging from +2.88% to -1.5%. The purity of the adhering sirup ranged from 76.5 to 53.7. The highest was from a factory using the Steffens process and contained raffinose; the latter figure was of questionable accuracy. Excluding these, the range is 75.1 to 58.1, av. 66.8. There was no relation between purity and rendement, or between purity and difference between rendement and crystal yield, or between purity and H₂O in the sugar. The sugars showing the greatest difference between rendement and crystal content gave the best appearing crystals. Sugars with higher content of CaO in the washed crystals gave relatively low purity of the sirup, and *vice versa*. This may be due to cooking from lower grade sirups and finishing in crystallizers. The lowest CaO (0.002%) gave the highest purity (74.7) except purities, possibly accounted for by raffinose. The highest CaO did not give the lowest purity, but the lowest purities were found among the higher CaO values. The av. CaO was 0.020%.

W. L. BADGER.

The effect of lead tannate clarification on the polarimetric determination of sugar, dextrin and starch. J. GROSSFELD. *Z. Nahr.-Genussm.* 29, 51-6(1915).—G. made a study of various clarifiers in an attempt to find one that would yield, for polarization, solns. which were not cloudy or dark colored. He found that a mixt. of equal amts. of 10% com. tannin soln. and Pb acetate gave good results. A blank detn. on the tannin soln. using equal quantities of it and Pb acetate and excess of K₂SO₄ soln. gave no rotation on polarizing. Detns. on known amts. of sucrose, invert sugar and lactose, using from 2 cc. to 20 cc. each of the tannin and Pb acetate solns. gave good results. In the case of starch sugar and glucose good results were obtained using 2 cc. of each of the tannin and Pb solns. Dextrin gave low results. Larger quantities of the clarifier cause low results for glucose and dextrin, but using small quantities of the clarifier, such as 0.1 cc., the results were good. The following directions are given for the polarimetric detn. of sugars in foods: Dissolve 10 g. in a little H₂O and transfer to a 100 cc. flask with an equal quantity of H₂O so that the vol. of liquid is 50-60 cc.; then add 2 cc. each of the tannin and Pb solns. (in the case of fresh fruit or beets use 5-10 cc., for honey use 1 cc.). After each addition shake hard. Then make up to mark with satd. K₂SO₄, adding it slowly with const. shaking. Let stand for a few min., filter through a dry paper, and polarize. If the filtrate is colored or cloudy place 50 cc. in a 55 cc. flask and add 2.5 cc. each of the tannin and Pb solns., shake, filter and polarize in a 220 mm. tube.

Sols. containing coal tar colors (such as fluorescein, eosin, Congo red, fuchsin) and caramel were decolorized by the use of the clarifier. *Conclusions:* The tannin-Pb acetate clarification is very successful for clarifying sugar and dextrin sols. The polarization value of sugar sols. shows no loss through this clarification. While dextrin is somewhat absorbed the error is very slight if small quantities of clarifier are used. Starch cannot be detd. this way because of its absorption in the ppt. Colored sols. can be practically decolorized.

H. L. LOURIE.

Notes on clarification. W. E. CROSS. *Revista industrial y agricola de Tucuman*, Sept.-Oct. (1914); *Louisiana Planter* 54, 286.—Of the many modern methods of clarification all are modifications of the carbonation or the sulfitation processes. The sulfitation process is efficient and inexpensive, but less thorough than carbonation. The best practice is to sulfur heavily and then to lime back to 0.8-1.0 cc. acidity. It is important to have the clarified juice entirely free from suspended matter, and this is better accomplished by filtration than by settling. After sepn. of suspended matter the acidity may be increased by the addition of SO_2 , H_3PO_4 or acid Na phosphate. A. GROSS.

The decomposition of reducing sugars. A. SCHWEIZER AND G. LOOS. *Arch. Suikerind.* 22, 1855-9(1914).—The effect of the absorption of atm. O by alk. sugar sols. was studied. A soln. containing a mixt. of sucrose and glucose was treated with 3% its wt. of $\text{Ca}(\text{OH})_2$ soln. (20° Bé.) and kept at a temp. of 28° for 3 hrs. in one expt.; in another, air free from CO_2 was passed into the soln. for 3 hrs. The 2 sols. were then treated with CO_2 until weakly alk. to phenolph., heated to 55° and filtered. An exam. of the filtrates showed that glucose decompn. had taken place in both cases but less color had been produced in the soln. through which air had been passed. E. H.

Experiments on the eradication of the beet nematode, Heterodera schachtii. H. C. MÜLLER AND E. MOLS. *Z. Ver. Zuckerind.* 64, 959-1050(1914).— NaNO_3 and $(\text{NH}_4)_2\text{SO}_4$ alone or combined, did no good and possibly increased the infection. K_2CO_3 , and especially Na_2CO_3 , greatly increased the infection. The continued use of NaNO_3 as a fertilizer is held to be partly responsible for the spread of the disease. S or NaCl were of no value in lowering the infection. Sugars (applied with the idea of increasing bacterial action in the soil) gave no positive results but indicated possibilities. 0.5% H_2SO_4 or 1% KOH did no good. The earth which clung to the beets when pulled was found to be badly infected, especially with cysts which developed the second season. Mixing this earth with 25% CaO killed all the active nematodes but did not affect the cysts. The removal of beets from the field with the earth adhering, and then the thorough sterilization of this earth, is strongly recommended. CS_2 , HCHO, and allyl alc. were all effective. To thoroughly disinfect one pot, 200 cc. CS_2 , 15 cc. 40% HCHO dild. to a 2% soln., or 10 cc. allyl alc., pure or dil., were sufficient. Planting onions between beet rows, or treating the soil with onion juice, had no effect, in spite of the expected action of the allyl thiocyanate. Peat meal increased the beet yield but did not affect the nematodes. Beet leaves increased the infection very greatly. Shallow plowing causes the nematodes to concentrate in the surface layer, and to attack the young beets very rapidly. Thinning then removes a large number of nematodes, and this is strongly recommended. Kuhn's method of planting a "collecting" crop and pulling when badly infected was modified by killing the collecting crop with FeSO_4 , and in this form was found to be very efficient. The necessity for using the microscope to det. when to kill the collecting crop is a disadvantage, but if 3 weeks in warm weather or 4 in cold weather are allowed from the time of sprouting, nearly the same results will be obtained as with the microscope. Submerging the soil for 1 year did not decrease the infection. Expts. were begun to select beets that seemed to be resistant in badly infected plots, but no results have yet been obtained. The greatest number of nematodes were found in the first 20 cm. from the surface; at a depth of 40 to 60 cm. the soil

was practically free from infection. The infection traveled, under most favorable conditions, 56 cm. in 3 months. This was reduced to 5 to 10 cm. by CaO . Larvae buried as deep as 50 cm. easily reached the surface in one season. W. L. B.

Kauri gum. JAS. B. AITKEN. *Pharm. J.* 94, 550(1915).—A descriptive account of the occurrence, mode of collection and com. grades of the gum. S. WALDBOTT.

Use of raw sugar in distilleries (WINDISCH) 16. Working up sugar beets into alcohol (BERLACH) 16. Yield of alcohol of refined and of raw sugar (FOTI) 16.

U. S., 1,139,620, May 18. H. WULKAN. Producing concentrated solutions of glucose by treating starch with dil. H_2SO_4 or HCl to form a dil. inversion soln. and reacting on fresh starch with this soln. The process is repeated until the desired concn. is obtained and the concd. soln. is then neutralized with borax.

U. S., 1,139,621, May 18. H. WULKAN. Moistening dextrin while agitating it in a double-walled vessel maintained at about $40\text{--}50^\circ$ by circulation of air through the jacket of the vessel. The air after passing through the cooling jacket is mixed with steam and the dextrin moistened with this mixt.

U. S., 1,140,353, May 25. G. H. BENJAMIN. Preserving cane, sorghum or beet-root by cutting into particles about 0.5 in. in thickness, mixing with sufficient Ca phosphate to neutralize the normal acidity of the juices and with enough diatomaceous earth to absorb any free juices, treating with dry heated air to remove some of the excess H_2O if necessary and pressing the material into masses of the size desired for packaging.

Brit., 530, Jan. 8, 1914. C. C. MOORE. Recovering starch from succulent starchy vegetable materials, such as starchy tubers and roots, *e. g.*, potatoes, cassava, sweet potatoes, artichokes, yams, etc., and starchy fruits, such as bananas, bread-fruit, etc., by drying or desiccating, usually after a suitable preliminary comminution or subdivision, then sufficiently grinding, dry, and finally treating the material by wet methods to obtain starch milk and to recover the starch. After the dry grinding, the material may be ground wet, mainly to free the loosened starch from the ruptured fibers. The starch milk obtained from the dry-ground fine material is treated as usual on starch tables or in starch centrifugals. As an example, materials such as cassava, etc., in their natural moist state, are coarsely ground, grated, chipped, sliced, or otherwise comminuted to small quickly drying particles. These particles are then dried as usual, as by means of rotary drums, belt driers, kilns, etc., sun-drying being unsuitable, until they are brittle or frangible. A temp. of 120°F . or less is suitable for the drying, but the temp. may sometimes be as high as 140°F .; in the earlier stages, hotter air can be used, vaporization keeping the material cooler. The dry fine-grinding can be done with any suitable mill or grinding app., as a buhr stone grinder, suitably to a fineness, with cassava, of 80 mesh, or better, 100 mesh. In prepg. the starch milk, wet grinding is preferable, but, after sufficiently fine dry grinding, simple stirring or agitating may be substituted. Where the material is not very finely dry-ground, it is often desirable to steep in addition to the wet grinding or agitation; fermentation may occur. When the fine dry-ground material is treated with H_2O and the resulting magma screened to give starch milk, the swollen fragments of fiber and non-starchy tissue are retained by the screen. From the resulting milk, starch is recovered in any convenient way. With dry, very fine material, the amt. of H_2O necessary to wash the starch from the fibrous matter in obtaining the milk is much diminished and, correspondingly, the concn. of the waste effluent from the starch tables is much increased, rendering easier its concn. for human or animal food. A short steep, preliminary to

making the milk, is sometimes desirable, particularly with potatoes; the steep liquor may be drawn off, and concd., or may pass into the H_2O for making the milk. The concd. product represents a concd. nitrogenous material, useful as a cattle food or as a raw material for making human food. The steep liquor, or effluent from the tables, or both together, may be evapd. down directly, or be strained, filtered, or filter-pressed to recover insol. materials, the clear liquor concd. to a sirup, the insol. matters added, and the whole dried. While the drying must not be at so high a temp. that the starch would be hydrolyzed, it should be as rapid as possible to inhibit enzyme action; various compds., for instance 0.20–0.25 % of $NaHSO_3$, relative to the cassava or potatoes, may be added for the same purpose, the yield and color of the starch obtained being improved. Thus, comminuted cassava tubers or potatoes, emerging from the chopping, grating, slicing, or like machine, are sprinkled with Na or Ca bisulfite, and may then be dried suitably. In this case drying is readily effected in the sun, or by air of normal temp., without fear of souring, blackening, etc. The dried material, particularly in the presence of bisulfite, may be stored indefinitely or shipped any distance. In the subsequent treatment with H_2O , a little SO_2 or bisulfite may be added. In the case of making starch from succulent vegetable materials, such as potatoes, cassava, etc., by ordinary methods, it often happens that, after the usual wet grinding, only about $\frac{1}{2}$ of the starch is recovered on the tables, the rest remaining on the sieves. The present process may be applied to these residues—by drying them to a brittle hardness, fine grinding, forming starch milk and recovering the starch on the tables.

Brit., 1,576, Jan. 20, 1914. M. WEINRICH. Purifying cane sugar or sirup by mixing it with lime and introducing into H_2O or juice simultaneously with CO_2 or flue gases, and neutralizing with H_3PO_4 , H_2SO_4 , or other acid. In treating raw sugar, the sugar may be made into a magma with H_2O in a mixer having toothed disks upon 2 shafts and scrapers or distance-pieces, and lime (preferably caustic, although slaked lime or milk of lime may be used) is fed in by a vibrating screen. The magma overflows by a pipe into 1 of a number of defecators containing H_2O , and the stirrers are at once started and CO_2 , etc., is introduced through pipes. An acid is added to complete the neutralization, or nearly so, and the soln. is heated by a coil and filtered. The raw sugar may be washed first, and the resulting sugar and sirup can be simultaneously treated. At the plantation factory, the 2nd and 3rd products are made into a magma with the raw cold juice and lime, and run into juice in the defecators, and the green sirup is limed and also run into juice. Cf. C. A. 8, 1028, 1029.

Ger., 281,056, Oct. 17, 1913. Addition to 276,489 (C. A. 9, 730). AKT.-GEM. FÜR ANILIN-FABRIKATION. In obtaining betaine hydrochloride from molasses, molasses slops, or other runnings from the beet-sugar manuf., the initial material is 1st acidified with HCl and dehydrated *in vacuo* at not over 60° , whereupon the betaine-HCl crystallizes out.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

U. S., 1,140,174, May 18. L. LILIENFELD. "Artificial leather" is made by coating paper or cloth with alternating layers of celluloid soln. mixed with *o*-tricresyl phosphate and a mixt. of viscose with the condensation product formed from Chinese wood oil 100 and *o*-toluidine 200 parts by the action of heat and $ZnCl_2$, emulsified with Na sulforicinoleate. Cf. C. A. 8, 1886.

Brit., 714, Jan. 10, 1914. D. B. MACDONALD. Treating leather splits and belly and shoulder portions, to render them solid, flexible, non-hygroscopic, waterproof,

and capable of holding stitches, by applying, on one or both surfaces, a soln. of celluloid, pyroxylin, cellulose acetate, or other ester or product of cellulose, such as viscose. Whole leather is preferably treated by drumming, soaking, or dipping, and cut-out parts, such as soles, may be brushed with the soln. With viscose, a complete satn. is necessary, whether the leather be whole or cut. Whole leather sheets or cut-out pieces are preferably levelled by rolling before being treated. Aniline dyes or stains may be added for application to boot soles, edges, or heels, the soln. being used on boots and shoes after they have been scoured, and the usual bottom dressing being omitted. Weltered insoles are treated on the flesh side and channelled edges, the need for a canvas backing to hold the stitching being thereby eliminated. Specified solns. contain in stated parts: (1) celluloid, pyroxylin, cellulose acetate or other ester, acetone, acetone oils or other ketone, benzene, petroleum benzine, wood naphtha or alc., amyl acetate, amyl alc., ethyl acetate, terpenes or oil of camphor, and glacial acetic acid; (2) celluloid, ethyl and methyl alc., light ketone and oil of camphor, this soln. being particularly suitable for boot-sole edges, bottoms, or heels; (3) pyroxylin, castor oil, ethyl alc., light ketone, benzene, and amyl acetate, this soln. giving a very flexible coating; (4) pyroxylin, camphor, and naphthalene; (5) a soln. of viscose in H_2O , this being non-inflammable. Wax may be added to facilitate edge-burnishing, and castor oil or resins or oleoresins, such as Canada balsam, may be added to the celluloid to confer flexibility.

Fr., 466,790, Mar. 12, 1913. J. BOILEY. In a quick tanning process, after deliming and before treatment with tanning agents, the skins are softened by means of alum or Al acetate (free from H_2SO_4 , Fe, and combustible matter) for 24-48 hrs.

Fr., 468,287, Feb. 10, 1914. O. LINDNER. In mfg. artificial sole leather, fiber felt, before pressing, is impregnated with K silicate and pumice, dried and pressed through calenders, softened with alc. and glycerol, again calendered, and impregnated with stearin and resin.

Ger., 276,286, May 31, 1913. A. VAN OORLAER. App. for dehairing animal skins.

Ger., 280,195, Oct. 17, 1912. M. KIND. Cooling gelatin and like materials by means of a current of filtered, cooled air which is recooled and returned to the process.

Ger., 280,233, Jan. 27, 1912. BADISCHE. Tanning animal skins by treating them with H_2O -sol. compds. which are obtained from $HCHO$ or substances generating $HCHO$ or reacting as $HCHO$, and aromatic hydroxy compds., alone or in admixt. with other tanning or non-tanning substances. By hydroxy compds. are to be understood those which contain 1 OH group per nucleus and in addition 1 or more other salt-forming acid groups. E. g., a moderately acid, concd. soln. of the Na salt of sulfonated methylene-*p*-hydroxybenzoic acid is dild. with H_2O until the soln. is about 5%. This liquor is used for tanning. The Na salt of the sulfonated methylene-*p*-hydroxybenzoic acid is obtained by dissolving 100 parts of methylene-*p*-hydroxybenzoic acid (obtained by acting with 1 mol. $HCHO$ on 2 mols. *p*-hydroxybenzoic acid, dissolved in conc. H_2SO_4) in 300 parts of conc. H_2SO_4 , and heating the liquid until a test remains clear upon dilg. with H_2O . The liquid is then cooled, poured upon ice, and pptd. with NaCl soln. Cf. C. A. 9, 393.

Ger., 281,351, Dec. 10, 1912. M. PAULS. Mfg. a leather substitute for shoe soles, wheel tires, and the like, by treating and satg. pressed or woven materials of any kind, with vegetable oil, especially thickened linseed oil, to which fat-containing dyes are added, and adding to the mass finely divided Fe, brass, Cu, Al, or the like metals. The product can be cut with a knife or stamped to form any desired shape.

30. RUBBER AND ALLIED SUBSTANCES.

The valuation of plantation rubber. J. M. VAN RESANDT. *India Rubber J.* 49, 700(1915).—R. advises standardization and the establishment of a central rubber station.
EDWARD J. KELLEY.

Hypothesis on the process of vulcanization. ANON. *Caoutchouc et gutta-percha* 12, 8601-2(1915).—In the vulcanized product the S exists in the colloidal state. When rubber is heated with S the resins and proteins react with it producing H_2S and SO_2 . Likewise metallic oxides, such as PbO_2 , ZnO_2 , etc., when heated with S in the presence of air, produce SO_2 and the corresponding metallic sulfides. At the proper temp. the following reaction takes place: $SO_2 + 2H_2S = 2H_2O + 3S$, colloidal S thus being produced. In the case of cold vulcanization by means of S_2Cl_2 , the latter compd. contains the colloidal S necessary; but since this colloidal S can not diffuse through the mass as in hot vulcanization, the product is vulcanized only on the surface.

Straight test pieces and ring test pieces for the mechanical testing of rubber. ANON. *Caoutchouc et gutta-percha* 12, 8603-4(1915).—A comparison of the 2 forms of test pieces. The ring test piece did not give an exact idea of the strength of rubber, but was preferred to the straight or rod test piece.

E. J. KELLEY.

Work of the Central Rubber Station for the (German) colonies. F. FRANK AND E. MARCKWALD. *Chem. Ztg.* 38, Rep. 587(1914).—The nitrogenous substance in the latex is a typical albuminoid with all the characteristic reactions. Research on the extn. of oil from Manihot seeds showed the seeds to be composed of about 55% husk and 45% kernel. The latter contained 55% of oil, which appeared to be free from obnoxious bitter principles, with properties resembling those of sweet oil.

E. J. K.

Castle rubber from India. ANON. *Bull. Imp. Inst.* 13, 17-8(1915).—A new source of rubber of somewhat inferior quality. Analyses are given.

L. G. C.

Rubber from Dominica. ANON. *Bull. Imp. Inst.* 13, 18-20(1915).—Physical properties and chem. comp. of various kinds of rubber grown in Dominica are given.

L. G. C.

Coconut water as a coagulating agent for latex. W. A. LEONARD. Colombo, Ceylon. *India Rubber Rev.* 15, 11(1915).—One or 2 ounces of coconut water which has been allowed to ferment for 4 or 5 days will coagulate 1 pint of pure latex. It is said to produce a better rubber than that obtained by the present method of using crude $AcOH$, especially as to color; and a cleaner rubber than that obtained by the cocco-fermentation acid treatment.

S. LEVY.

Electrical coagulation. ANON. *India Rubber J.* 49, 218(1915).—The latex is well sieved and poured into oblong tanks, after which the electrodes (consisting of rods contained in porous pots), which are fastened in a lid, are placed in the vessels and the current passed. Coagulation takes place at the positive pole, which becomes covered with a solid layer of rubber, while the negative pole remains clean. After one-half hour the current is reversed. The whole process is completed in 1 hr.

E. J. K.

The "Derry" smoking process. ANON. *India Rubber J.* 49, 631-2(1915).—The process consists of coagulation by sepn. of the H_2O from the caoutchouc in the latex by heat and smoke in concentric layers between films of smoke on a travelling belt. Every particle is exposed to the action of smoke and polymerized.

E. J. K.

Tapping and the storage of plant food in *Hevea brasiliensis*. L. E. CAMPBELL. *India Rubber J.* 49, 735-6(1915).—The effects of tapping on the trees were almost purely

local, especially in a horizontal direction. C. concludes that by changing the tapping from one part of the tree to another at intervals, the resting period of each area is nearly as effective as if the whole tree were allowed to rest.

E. J. K.

A new disease in Malaya. F. T. BROOKS. *India Rubber J.* 49, 736(1915).—The bark on one side of the rubber tree dies, and the wood beneath it becomes brown in color. In advanced cases the disease spreads up the trunk to a height of 2 or 3 feet. It is due to a fungus growth, probably one of the *Xylariaceae*.

E. J. K.

Testing of rubber gloves for insulating power. ANON. *India Rubber World* 51, 123(1914).—The usual practice in testing gloves is to fill them with H_2O and immerse them in a can of H_2O . Electrodes are immersed in the H_2O in the glove and the H_2O in the can, and the current applied gradually and uniformly to from 3,000 to 10,000 v., depending upon the kind and quality of glove and the service for which it is intended. The test-voltages employed vary from $1\frac{1}{4}$ to 2 times the voltage of the circuit upon which the gloves are to be used, and are applied from 1 to 5 min. An ammeter is connected in the test circuit and all gloves are rejected whose insulation resistance is so weak that the current flowing through the glove exceeds 10 milliamp. at 10,000 v. An illustration is given showing the glove testing equipment of the Elec. Testing Lab., New York.

S. LEVY.

Diffusion of carbon dioxide through rubber (RODT) 2.

Brit., 418, Jan. 7, 1914. T. H. CRUSE and J. H. BRISCOM. A puncture-sealing composition, to be inserted in the inner tubes of tires, consists of white dextrin, washing-soda, and H_2O . The dextrin and soda are mixed dry, and warm H_2O is added, the proportions varying from 1 oz. dextrin and 1 dram soda to 6 oz. dextrin and 6 drams soda, to half a pt. of H_2O .

Brit., 528, Jan. 8, 1914. K. TARASSOV. Phenol-formaldehyde condensation products are obtained by the action of $HCHO$ or its polymers, etc., on mixts. of phenol or its homologs with sulfonated fats or fatty oils, aromatic sulfo fatty acids, or the sulfonic acids obtained by sulfonation of naphtha, petroleum distillates, or other hydrocarbon oil. According to the conditions of the reaction, sol. resinous substances or hard insol. products may be obtained. The sulfonated compd. employed enters into the comp. of the product, increasing its elasticity, and also acts as a catalyst in the reaction, so that other catalysts may be dispensed with. According to examples, sulfonated castor oil, the aromatic sulfo fatty acids obtained according to 4,741, 1898, from naphthalene and oleic acid, a mixt. of sulfonated castor oil, sunflower-seed oil, or rapeseed oil, and sulfonated vaseline oil, are used. Instead of $HCHO$, paraformaldehyde, trioxymethylene, hexamethylenetetramine, or other substance having active CH_2 groups, may be used. The liquid, resinous, or rubber-like intermediate condensation product may be mixed with sand, sawdust, asbestos, fibers of cellular bodies, etc., before the final product is obtained. Cf. C. A. 9, 980.

Brit., 1,199, Jan. 16, 1914. W. G. GASS. Machine for washing, macerating, or creping rubber, etc.

Brit., 1,200, Jan. 16, 1914. W. G. GASS. App. for washing rubber, particularly scrap rubber mixed with bark, sand, etc.

Brit., 1,111, Jan. 15, 1914. P. SCHIDROWITZ and H. A. GOLDSBROUGH. Porous or spongy rubber is made directly from rubber latex by coagulating the latex under conditions which yield a porous or spongy coagulum, and by fixing the pores so produced by vulcanization. The vulcanizing agent may be added prior to, during, or after coagulation, and vulcanization may be carried out in the wet state; the coagulant may

be such that the heat of vulcanization may bring about the coagulation, so that the sponginess is produced during vulcanization. The coagulum need not be purified. Coagulation may be effected by means of a coagulant, by heat, or by the use of a rubber solvent or ppt. Examples of coagulants are: HOAc, organic acids which are comparatively insol. in cold H_2O or latex but which dissolve on heating, acid salts for hevea latex, CS_2 , C_6H_6 , acetone, alc., and salicylic acid. There may be added, before, during, or after coagulation, substances which generate gases when heated or by chem. action, such as carbonates or sulfides or other suitable S compds., or NH_3 . Vulcanization may be effected by S as such or in soln., or by compds. which liberate S. Fibrous substances, fillers, etc., may also be added. Washing-gloves, etc., may be made by dipping a suitably shaped article, which may be made of fabric such as Turkish towelling, into the latex. The invention is applicable also to the manuf. of upholstery, flooring, golf balls, rowing-pads, etc.

Fr., addition 18,428, Nov. 10, 1913, to 456,598. BAYER & Co. Ebonite-like products, substitutes for rubber, are obtained by vulcanizing the Kondakov polymerization product of β,γ -dimethylbutadiene in the presence of piperidine, pyrrolidine, β,β -dimethyl- Δ -methyltrimethyleimine or dimethylamine.

Ger., 279,649, Nov. 16, 1913. F. KEMPTER. Mixing machine for rubber.

Ger., 280,848, Nov. 13, 1913. Addition to 259,253 (C. A. 7, 3242). H. COLLOSEUS. Separating caoutchouc, gutta-percha, or balata from saps yielding these gums. Instead of the alkali specified in the principal process, any substance may be worked up with the sap which reacts with the alk. earth, earth, or heavy metals salts with the formation of H_2O -insol. compds. Also, the order in which the additions are made may be varied at will. If the additions are of a neutral character, the addition of a small amt. of alkali is imperative. Good results are secured by adding water-glass, borax, Na_3PO_4 , and an alk. earth, earth, or heavy metal salt, to the sap, in any order. Furthermore, by the double decompn. of Na_2SO_4 with alk. earth salts, coagulation of the sap may be effected readily. The same result is attained by conducting CO_2 through the sap to which alk. earth salts have been added. At the time of coagulation, emulsifying agents, such as soap, albumin, or the like, may be added. Also, the serum which seps. from the coagulated caoutchouc possesses strong coagulating properties, and may therefore be employed for that purpose. E. g., 1 kg. kickxia sap is mixed with 85 cc. of a 25% $CaCl_2$ soln. The sap is then neutralized, and 60 cc. of a 10% alkali soln. are added with constant stirring.

Ger., 280,959, Mar. 21, 1912. BAYER & Co. Mfg. caoutchouc by subjecting isoprene to the action of metals of the alkali or alk. earth group in such manner that the metals come more or less completely into contact with the vapor of the hydrocarbon. E. g., a Na or K wire is introduced into the vapor of isoprene boiling under a reflux condenser. After several days all the isoprene has disappeared from the flask. It is found as caoutchouc around the alkali metal wire. If the alkali metal is immersed in the boiling isoprene, the polymerization requires from 3 to 4 times as long. Ca or Ca-Na may be employed instead of K or Na.

CHEMICAL ABSTRACTS

I. APPARATUS.

L. C. JONES.

Gas washing apparatus with enclosed filter. E. R. WEAVER AND J. D. EDWARDS. *J. Ind. Eng. Chem.* 7, 534-5(1915).—Three forms of gas-washing app. for analytical purposes are described with cuts. ISADOR MILLER.

Pipetting with the suction pump. FERDINAND PILZ. *Z. landw. Versw.* 18, 29-31 (1915).—The Mohr valve (of metal or glass) is bored as shown. A small metal tube (not shown) is inserted through the hole in the rubber tube *B* into the hole in the valve *A*, to prevent slipping. The hole at *a* being closed with the forefinger, a pressure of the other fingers permits the suction to act.

L. J. GILLESPIE.

Gas burner with screw. ANON. *Chem. Ztg.* 39, 352(1915).—The burner is screwed into the gas pipe, instead of rubber tubing being used.

J. H. MOORE.

Combustion boat. ANON. *Chem. Ztg.* 39, 370(1915).—The boat is covered for about $\frac{2}{3}$ of its length at one end to prevent the substance spitting up on the combustion tube. A hole on top of the covered end permits circulation of air.

J. H. MOORE.

Vacuum-tight lead seals for leading-in wires in vitreous silica and other glasses. HENRY J. S. SAND. Nottingham. *Proc. Phys. Soc. London* 26, 127-30(1914).—Pb free from oxide when allowed

to solidify in contact with glass forms a vacuum-tight joint, and on account of the firmness of the contact and plasticity of Pb these joints can stand temp. changes. The following procedure is recommended for quartz glass: A short piece of Mo wire is mounted in the sealing off tube, one end extending into the vacuum chamber for use as an elec. terminal, the other end projecting into an enlargement of the tube which is to be filled with Pb. A second chamber above contains the piece of Pb. The air is blown out with H, the tube then exhausted to 1 or 2 mm. and then sealed at the top. The quartz is then softened and pinched onto the Mo wire. After this the Pb is melted and allowed to filter from any oxide through the capillary to the chamber below. Before it solidifies the tube at the top is broken, allowing atmospheric pressure to force the Pb well against the surface of the glass. The tube is then cut at a suitable place and a tinned leading-in wire introduced. These seals have been used very successfully for X-ray tubes, Hg lamps, etc. PAUL D. FOOTE.

A new two-circle goniometer, its use and accessories. F. STÖBER. *Gent. Z. Kryst. Min.* 54, 442-57(1915).—A vertical ring 23 cm. in diam. is screwed to a cast iron foot. A graduated circle turns within the ring about a horizontal axis. Upon this a smaller graduated circle is so set up that its axis of rotation is at right angles to that of the first. The collimator and telescope can both be turned about a vertical axis. The app. can be used for one circle or two circle goniometric, spectrometric, or total reflectometric measurements; for measuring optical axial angles; for detg. op-

tical orientation of biaxial crystals; for measuring extinction angles; and to cut oriented faces. Methods of adjustment are given in detail.

A. WANDTKE.

Model for the illustration of Röntgen ray interference phenomena. F. VON HAUER. Freiburg. *Z. Kryst. Min.* 54, 458-60(1915).—The model is made up of 2 intersecting circles upon which are mounted conal envelopes that touch at a single point. The axes of the cones correspond to the atomic rows upon which the parallel Röntgen rays, whose primary ray lies in the conal envelope, fall. The directions of intersection of both envelopes, where the interference maxima are especially strong, correspond to the primary and bent rays. The latter makes the same angle with the crystallographic network plane drawn through the atomic rows as does the primary ray and consequently appears as though reflected upon this plane. If a photographic plate is considered to be placed at right angles to the primary ray, a black point must result for this ray as well as for the bent ray.

A. WANDTKE.

A home-made centrifugal pump. MAX ORTLI. *Z. physik. chem. Unterr.* 28, 95(1915).—A solid wooden wheel is attached to the end of a shaft that may be revolved rapidly. A glass tube a little longer than the radius of the wheel is bent at right angles near one end, the other end being drawn to a small nozzle, and attached to the plane face of the wheel so that the shorter end coincides with the axis of the wheel. A rubber hose on this end leads to a vessel containing H_2O which is pumped out when the tube is filled and the wheel revolved.

J. H. MOORE.

Viscosimeter for lubricants. H. K. VON VLOTEN. Amsterdam. *Chem. Weekblad* 12, 429-30(1915).—A metal strip is coated on both sides with the lubricant, and placed between 2 cylinders, held against it by weights. Known wts. are hung on the strip, and from the relation between the various wts. at equil. the viscosity of the lubricant is detd.

G. W. MOREY.

A new device for sterilization. ERNST DEUSSEN. *Pharm. Zig.* 60, 180(1915).—The app., a one-piece affair designed for sterilizing glass containers, consists essentially of a straight glass tube (7 cm. inner diam.) 22 cm. in length, in about the middle of which is blown a small spray trap. The slightly longer upper limb at a point just above the trap is blown into a shallow glass plate on which is placed in inverted position the object to be sterilized. The plate in turn carries an exit tube pointing downward. The app. is attached by means of a rubber stopper to the neck of a round bottom liter flask, in which H_2O is boiled.

Chemihydrometry. B. F. GROAT. *Science* 41, 864(1915).—This name is suggested for the method of measuring by chemical means the flow of rivers, discharge of turbines and capacities of reservoirs. There are some objections to the name and G. asks that others be submitted.
E. H.

The coëxistence of phases which are subjected to different pressures. P. NIGGLI. Zurich. *Z. anorg. Chem.* 91, 107-33(1915).—A derivation by means of the thermodynamic potential of equations representing the conditions under which different phases can coëxist when subjected to different pressures. In the case of equil. between liquid-liquid, the osmotic pressure, in the case gas-liquid, capillary processes, and in the case of a stationary pressure gradient in a liquid or gaseous system, forces such as gravitation, are to be considered. When the phases concerned are liquid-solid the cases of (1) uniform hydrostatic pressure, (2) non-uniform hydrostatic pressure, (3) non-uniform pressure are to be distinguished. Case (1) leads to the Clausius-Clapeyron

equation; case (2) to a general equation, of which the familiar equation representing the change of m. p. of a solid subjected to uniform differential pressure is a special case, and which is extended to soln. and fusion processes in binary systems; case (3) to a still more general equation of which the preceding are special cases. The application to geologic processes is discussed.

GEORGE W. MOREY.

Monovariant systems of moderately soluble hydrolyzable salts and the method of physico-chemical analysis. E. I. SHEPITAL'SKII. *J. Russ. Phys. Chem. Soc.* 46, 641-81 (1914).—An extensive mathematical treatment of the application of the principles established in a previous investigation (cf. *C. A.* 8, 3144) to the exam. of equil. systems of salt solns. in presence of foreign acids. The application consists in a chem. analysis of several monovariant systems of solns. of the same salt at the same temp., but in presence of different amts. of the foreign acid. Since the conc. of the undissociated mols. of the acid of the salts with which the soln. is satd. at a given temp. is a const. quantity, independent of the presence of other substances in the soln., and since the "stability product" is also const. under these conditions, one can, by examining a sufficient number of such systems, in most cases obtain such a number of algebraic equations as will make possible the finding of all the unknowns. The main condition for the applicability of these principles is that the hydrolyzable salt be only moderately sol., so that, while its soln. will contain enough material for analysis, it will not become so conc. as to make the laws of equil. inapplicable. The method is illustrated with numerous details which cannot be abstracted and with a lengthy discussion of Sherill's work (*C. A.* 2, 930), some of whose assumptions are considered arbitrary. A more thorough criticism of this work is promised for the near future.

H. M. GORDIN.

Atomistics of chemical reactions in anisotropic substances. G. TAMMANN. Göttingen. *Z. anorg. Chem.* 91, 263-76(1915).—The atomistics of reactions taking place in isotropic and anisotropic substances are discussed, the latter by means of equations, developed on thermodynamic grounds, representing the relation between concn. and the temp. of the beginning and of the end of the transition $\alpha B \rightleftharpoons \beta B$ in the binary system AB, in which mixed crystals are formed. The course of the transition curve of AgI in the binary system AgI-AgBr was detd. by observing the temp. at which the solid solns. of various concns. became cloudy; addition of about 10% AgBr lowers the transition temp. from 141.5° to 115°, after which the further addition of AgBr has but little effect. "Tempering" the mixts. at higher temp. for some time had an appreciable effect on the transition phenomena, probably due to a more uniform mixing of the components.

GEORGE W. MOREY.

The sensitiveness of a chemical reaction. A. G. BARLADREAN. *Schweiz. Apoth. Ztg.* 53, 257-60, 273-6(1915).—The sensitiveness of a chem. reaction (cf. Gorski, *C. A.* 7, 2882-3) has a definite value only under well-defined conditions, e. g., pptn. of BaSO₄ in excess of BaCl₂ or H₂SO₄, NH₄Cl or NaCl. Cu ion in a conc. of 1:1,000,000,000 is detected by its toxic action on *Spirogyra* when 5-10 threads are used and the vol. is not less than 1 liter (*C. A.* 8, 989). When the vol. is only 100-500 cc., the Cu conc. remaining the same, the cells will not die. They will survive also when 50-100 threads are placed in a larger vol., e. g., 1 liter or more. But the sensitive *Spirogyra* test fails completely, even with large amts. of Cu ions present, when the water contains Ca salts.

S. WALDBOTT.

Conjugated reactions, or oxidation-reduction reactions from the electronic point of view. G. DAIN. *J. Russ. Phys. Chem. Soc.* 46, 845-63(1914).—A detailed presentation of the view that all oxidation-reduction reactions consist in a transfer of negative electrons from 1 element to another, and the application of this view to the balancing of chem. equations. Such reactions are called "conjugated," and the distinction between valence and value is made clear, valence having the meaning usually

given to this term, while value may be positive or negative according to the nature and number of elec. charges. The direction of the passage of electrons from one element to another follows the periodic system, going from the 1st to the 7th group. In the subgroups the direction is from the higher to the lower at. wts. for the 1st subgroups, and in the opposite direction for the 2nd subgroups. In diatomic elements the 2 atoms have different charges, while in monoatomic, *e. g.*, Hg, the number of positive and negative electrons is the same. Numerous details are given, but there is little new in them.

H. M. GORDIN.

Oxidation of alcohols in the presence of ferrous oxide and ferrous salts. A. G. DOROSHEVSKII AND A. YA. BARDT. *J. Russ. Phys. Chem. Soc.* 46, 754-85 (1914).—The authors intend to exam. the action of charcoal (wood) on solns. of alc. The influence of temp., diln., nature of the charcoal, the relation between the amts. of alc. and charcoal and the extent of oxidation will be examd. later. The present work concerns chiefly the mechanism of the oxidation. The numerous expts. resulted in the following conclusions: The difference in the oxidizing power of different varieties of charcoal is partly due to a difference in the amts. of adsorbed O they contain. Hence as an oxidizing agent charcoal may be "killed" by repeated heating to 280-300° *in vacuo* and cooling in an atm. of CO₂ obtained by calcining MgCO₃ (the CO₂ from CaCO₃ + HCl always contains air). That the adsorbed O is, however, not the only active agent in charcoal is shown by the fact that some samples of charcoal are perfectly passive even though they have been exposed for a long time to the air, and that pure charcoal from sugar is also inactive. Further exam. showed that just as the decolorizing properties of charcoal depend upon the presence of certain salts (Classner-Suida, *Ann.* 357, 95), and its ability to catalytically decomp. alcs. depends upon its containing Si compds. (Senderens, *C. A.* 1, 1386), its oxidizing effect is closely connected with the presence of ferrous salts (FeCl₂, FeSO₄, FeC₂O₄, etc.). Hence, charcoal may be "killed" not only by removing its adsorbed O as above, but also by oxidizing its ferrous to ferric salts; this is proved by expts. On the other hand, "dead" charcoal may be "resuscitated" by again impregnating it with O and reducing the ferric to ferrous salts, both of these purposes being accomplished by the established custom of calcining exhausted charcoal (causing a reduction by the C) and allowing it to cool in the air (to readorb O). MeOH, EtOH, PrOH, BuOH and *iso*-BuOH are readily oxidized by KMnO₄ or H₂O₂ in the presence of ferrous salts. The oxidation product of EtOH in case KMnO₄ + FeSO₄ are used is almost exclusively MeCHO, while KMnO₄ + FeC₂O₄ yield MeCHO + AcOH. In both cases the reaction is so regular that its progress may be followed quant. H₂O₂ + FeSO₄ also yield MeCHO + AcOH, the former predominating, while H₂O₂ + FeC₂O₄ give the same products, but the AcOH predominates. The reaction with H₂O₂, however, is not so regular as that with KMnO₄. The oxidation of EtOH by H₂O₂ + FeCl₂ may be shown as a lecture expt. either by adding to the alc. (50%) a soln. of fuchsin-H₂SO₄, or by observing the evoln. of bubbles of O. Since charcoal oxidizes alcs. only in presence of O and Fe salts, its action must be merely catalytic, and the oxidation a joint reaction, both the alc. and the FeO being oxidized. It also follows that the oxidizing properties of a charcoal may be enhanced by the addition of ferrous salts. Owing to the nature of adsorption and the liberation of FeO by the (slight) alkalinity of C, the FeO ought to conc. on the surface of the charcoal particles. On the other hand, from a mixt. of H₂O and alc. the latter is adsorbed in greater quantity than the former. Since the seat of adsorption as well as that of oxidation is thus on the surface (or in the pores) of the charcoal, there must be a close connection between its adsorbing and oxidizing powers; this is corroborated by expts. Thus animal charcoal is both a better adsorber and a better oxidizing agent than wood charcoal. Dil. alc. is more easily oxidized than concd. Several tables and curves illustrate the expts. H. M. GORDIN,

Acceleration of the oxidation of aluminium by means of mercury. J. F. MC-CLENDON. Univ. Minn. *Biochem. Bull.* 4, 96(1915).—Al will burn rapidly in dry air (humidity 10% at 20°) if a trace of Hg is driven into it by an elec. spark. The white oxide is formed so rapidly that it appears to grow "out of the metal as plants grow out of the ground, attaining the height of a mm. in a few min." Part of the liberated energy is expended in lifting the wt. of the oxide against gravity. A. P. L.

Catalytic influence of kaolin on the combination of oxygen and hydrogen. J. JOANNIS. *Compt. rend.* 158, 501-4(1914); cf. *C. A.* 8, 3277.—A measured vol. of H and O in the proper proportions to form H₂O was passed over a layer of kaolin at a definite temp., and the amt. of H₂O formed in each expt. was detd. From the results obtained it was shown that H and O unite in the presence of kaolin at a temp. at which no combination takes place in a plain glass tube. Combination began at 230° in the presence of kaolin. The amt. of water formed was proportional to the time of contact between the kaolin and the gaseous mixt., and the activity of the kaolin was influenced by the temp. to which it had been heated previous to the expts. Heating to a high temp. decreased its activity as a catalyzer. E. B. MILLARD.

J. Liebig's idea of osmotic pressure. I. P. OSIPOV. *J. Russ. Phys. Chem. Soc.* 47, 26-9(1915).—J. Liebig should be given the credit for having first described the phenomenon of osmotic pressure, though he did not use this term (31st letter, *Chemische Briefe*). H. M. GORDIN.

A kinetic interpretation of osmotic pressure. P. EHRENFEST. *Verslag Akad. Wetenschappen* 23, 1264-8(1915); *Proc. Akad. Wetenschappen* 17, 1241-5(1915).—A general equation for osmotic pressure is developed by the aid of the kinetic theory. G. W. MOREY.

Spontaneous crystallizability. PAUL OTHEMER. Göttingen. *Z. anorg. Chem.* 91, 209-47(1915).—Crystallization is considered as made up of 2 processes, not wholly independent, viz., (1) a change in the internal energy of the molecules, which causes them to become anisotropic and (2) an arranging of the anisotropic mols. in a crystal structure. Both can be developed as probability functions, and exptl. detns. of the number of crystal nuclei formed show variations similar to those of a probability curve. To det. whether or not anisotropic mols. existed at temps. above the m. p., small amts. of various substances, e. g., piperonal, were heated at various temps. above the m. p., then cooled and subjected each to the same treatment, and the number of cryst. nuclei detd.; if more nuclei were formed after heating at a temp. slightly above the m. p. than at a temp. much above the m. p. it would indicate that anisotropic mols. persist, their number decreasing with increasing temp. Expts. confirmed this view, the number of nuclei formed decreasing rapidly with increasing temp. Certain substances show an abnormally high entropy change on fusion, which is assumed to be due to formation of new mol. species of high entropy content. If these new mols. do not tend to become anisotropic, such melts on undercooling should show an abnormal increase of the spontaneous crystallizability with the duration of the undercooling. Expts. with various fatty acids, which show an abnormal entropy change on fusion, confirmed this conclusion. Several triglycerides which are known to exist in stable and unstable forms were studied; the fact that the m. p. of the unstable form can be realized is "explained" by stating that the spontaneous crystallizability (measured by the number of crystal nuclei) of the unstable form is much greater than that of the stable form, that the crystallizability of the stable when formed from the unstable form is very small, and that the linear vol. of crystn. of the unstable form is greater than that of the stable form. Metals were found to increase the number of crystal nuclei formed, due to some substance of unknown nature given off by the metal. G. W. MOREY.

A chemical explanation of the irregular crystal water content of $3\text{CdSO}_4 \cdot 8\text{H}_2\text{O}$. C. BLOMBERG. Amsterdam. *Z. anorg. Chem.* 91, 248-50(1915).—The fact that 8 H_2O are combined with 3 CdSO_4 indicates the formation of complex ions in H_2O soln., i. e., $3\text{CdSO}_4 \rightleftharpoons [\text{Cd}_3\text{SO}_4]^{++} + [\text{Cd}(\text{SO}_4)_2]^{--}$. Other cases of irregular crystal H_2O content may be explained in a similar manner. G. W. MORREY.

The metastability of metals in consequence of allotropy and its significance for chemistry, physics and technics. IV. E. COHEN. *Verslag Akad. Wetenschappen* 23, 1220-4(1915); cf. *C. A.* 8, 1223, 2295; 9, 987.—It follows from the fact that ordinary pure metals are metastable systems composed of more than one mol. species, that thermal const. detd. without regard to the mol. state of the substance will be indefinite and discordant. Heats of reaction will be different for various modifications, e. g., in the case of Cd the difference between the heat of soln. of electrolytic (γ) Cd and ordinary Cd may be as much as 4.3%. Similarly, the latent heat of fusion exptly. detd. will differ according to whether the final state corresponds to one or another modification, e. g., the latent heat of fusion of Cd as given in the literature is 13.7 cal., while the heat of transition γ - α Cd at ordinary temp. is 6.6 cal. The wide discrepancies in the latent heats of fusion as given in the literature may be caused by uncertainties as to the mol. species to which the exptl. data apply. GEORGE W. MORREY.

The allotropy of bismuth. II. E. COHEN. Utrecht. *Verslag. Akad. Wetenschappen Amsterdam* 23, 1224-6(1915); *Proc. Acad. Wetenschappen* 17, 1236-8(1915).—Measurements with a dilatometer on Bi indicated that the pure metal exists in 3 allotropic forms, instead of 2 as previously believed (*C. A.* 8, 305). G. W. M.

The temperature coefficients of surface tension in binary mixtures. M. PADOA AND A. MATTEUCCI. Univ. Bologna. *Atti accad. Lincei* 23, II, 590-5(1914); cf. P. and Tabellini, *C. A.* 8, 2092.—In the preceding paper results were given tending to show by means of the surface tension the degree of association between solvent and solute. In continuing these expts. it seemed useful to study the behavior of (1) mixts. of 2 non-associated solvents; (2) mixts. of an associated and a non-associated solvent; (3) solns. of solids in non-associated solvents. The surface tension was measured by the drop method. Normal solns. of toluene in C_6H_6 and C_6H_6 in toluene show a normal temp. coeff. for surface tension and, therefore, show no association. Cyclohexanone in C_6H_6 shows a feeble association which is at a max. in 2 *N* solns. of cyclohexanone in C_6H_6 . A *N* soln. of naphthalene in C_6H_6 is likewise feebly associated. In mixts. of C_6H_6 and PhOH there is in general a stronger association than in the component liquids. With mixts. nearly monomol. the temp. coeff. is at a max., i. e., the association is at its minimum. E. J. WITZEMANN.

Heat of formation of vanadium pentoxide and the vanadium chlorides. OTTO RUFF AND LOTHAR FRIEDRICH. Danzig. *Z. anorg. Chem.* 89, 279-306(1914).— VCl_4 is easily prepd., but slowly decomp. at ordinary temp. into $\text{Cl} + \text{VCl}_3$; the latter compd. also decomp. with formation of $\text{VCl}_3 + \text{VCl}_4$. The equil. pressure of Cl in the system $\text{VCl}_4 + \text{VCl}_3 + \text{VCl}_2 + \text{Cl}$ could not be detd. directly, so the heats of formation of the various compds. were detd. in order to calc. approx. the equil. pressure; sp. heats were not detd. V burned in O in a Berthelot bomb does not give complete combustion; the heat of formation of V_2O_5 was calcd. from detns. of the heat the reactions $\text{S} + \text{Na}_2\text{O}_2 + \text{O}$; $\text{S} + \text{Na}_2\text{O}_2 + \text{O} + \text{V}_2\text{O}_5$; $\text{Na}_2\text{O}_2 + \text{V} + \text{O}$; the heat of formation of V_2O_5 from the heat the reaction $\text{S} + \text{Na}_2\text{O}_2 + \text{O} + \text{V}_2\text{O}_5$, in conjunction with the above detns. The heats of formation of VCl_4 and VOCl_3 were detd. from the heat of reaction with alkali and H_2O_2 ; the heat of soln. of 1 mol. V_2O_5 in a soln. of 22.75 $\text{NaOH} + 8\text{H}_2\text{O}_2 + 177\text{H}_2\text{O}$ is 46.1 cal. The above method could not be used with VCl_4 due to a too slow rate of soln., and did not give good results; better results

were obtained by combustion in O and detn. of the amt. of Cl, V_2O_5 and $VOCl_3$ formed; with VCl_3 C was added to promote combustion. The heats of formation (from the elements) per mol. obtained are: V_2O_5 , 302 ± 10 cal.; V_2O_6 , 437 ± 7 ; $VOCl_3$, 200 ± 4 ; VCl_3 , 147 ± 4 ; VCl_2 , 187 ± 8 ; VCl_4 , 165 ± 4 cal. VCl_4 is endothermic in regard to $VCl_3 + Cl$; at room temp. the reaction is $VCl_4 \text{ equil.} = VO_2 \text{ solid} + Cl_2 + 44$ cal.; VCl_4 becomes stable at about 630° .

GEORGE W. MOREY.

Influence of colloidal sulfur on the freezing point of aqueous solutions of some electrolytes. M. RAFFO AND G. ROSSI. Univ. Bologna. *Gazz. chim. ital.* 45, I, 119-22(1915).—It has been shown (C. A. 7, 437) that colloidal S affects the elec. cond. of the crystalloids, H_2SO_4 and Na_2SO_4 , which are always present in solns. of colloidal S. These crystalloids are called "crystalloids of formation." If additional H_2SO_4 or Na_2SO_4 is added to the colloidal soln. the cond. of the added portion is not affected (*Ibid* 44, I, 76; cf. C. A. 8, 1367). Paterno and Cingolani (*Ibid* 44, I, 37; cf. C. A. 8, 1691) found that colloidal S does not affect the electrolytic dissociation of added salts as detd. by the f. p. method and concluded that it does not affect the f. p. R. and R. repeated their own expts. using the f. p. method. The f. p. of a dialyzed colloidal S soln. which still contained a determinable amt. of H_2SO_4 and Na_2SO_4 was detd. The same soln. was exposed to the light to ppt. the S and the f. p. again detd. To some of the same soln. solns. of $LiCl$, Li_2SO_4 , Na_2SO_4 and H_2SO_4 were added and the f. p. detd.; these solns. were then exposed to the light to coagulate the S and the f. p. again detd. The rise in f. p. produced by the addition of colloidal S is the same in all cases. When the S had been removed the f. ps. were 0.11° lower in all cases. The expts. show that the colloidal S particle influences the crystalloids of formation, Na_2SO_4 and H_2SO_4 , in such a way as to make the f. p. higher than that of the same mixt. of crystalloids in the absence of S, but has no influence on the f. p. of crystalloid solns. added, even if these are H_2SO_4 or Na_2SO_4 . This confirms the earlier deductions from the elec. cond. of similar solns. under the same conditions and shows again that the crystalloids of formation in the presence of colloidal S are not able to conduct electricity or to lower the f. p. to the same extent as the same solns. free from colloidal S particles.

E. J. WITZEMANN.

Behavior of colloids toward pure and mixed liquids. I. Systems: caoutchouc-benzene-alcohol and caoutchouc-benzene-acetone. W. A. CASPARI. London. *J. Chem. Soc.* 107, 162-71(1915); cf. C. A. 8, 1214.—Caoutchouc was selected as a colloid which could form 2 phases in stable equil. such that the whole system could be represented by isothermals expressing all possible equilibria between the substances involved. It was found to ppt. reversibly from solns., and to be subject to little internal change when in contact with solvents, except for deviscification and the corresponding change in solubility, which took place slowly and to only a small extent when fresh sound material was used. The sol. constituents of India rubber mixed in all proportions with solvents such as C_6H_6 , giving a highly viscous soln. at high concns. They are wholly insol. in such precipitants as acetone and EtOH, and the solubility of these liquids in caoutchouc was wholly negligible. Solns. of caoutchouc of known conc. were titrated with alc. until sepn. into 2 phases just set in. Each limiting triad obtained represented a point on the binodal curve. In other expts. an excess of alc. was added, giving rise to 2 fluid layers with most of the caoutchouc in the lower one. Caoutchouc was insol. in mixts. of 43 vols. of alc. to 100 C_6H_6 and in 80 vols. or more of acetone to 100 of C_6H_6 . Diagrams are given showing the equil. in each mixt. The point of transition from sol to gel was about at 1 vol. of caoutchouc to 6 of C_6H_6 .

Emulsions and emulsification. F. G. DONNAN. *Engineering* 99, 551-2(1915).

—A general lecture with expts. When oil was allowed to flow from a pipet bent upward and under water, the oil rose to the surface in drops. If alkali was added to the water, the oil then rose in a fine stream, no longer in drops. E. B. MILLARD.

Capillary pressure in gas bubbles. ERWIN SCHRÖDINGER. Vienna. *Ann. Physik* 46, 413-8(1914); *Chem. Zentr.* 1915, I, 724-5.—In the approximation formula for the pressure at which an air bubble escapes from a capillary tube of given radius into a liquid, the second term has been corrected, and some consequences of the theory have been detd. E. B. MILLARD.

Hydration problem. II. A new method for the determination of the electrolytic transportation of water. HEINRICH REMY. Freiburg. *Z. physik. Chem.* 89, 529-69 (1915); cf. *C. A.* 9, 1569.—Since the ions are hydrated in aq. soln., it follows that on conducting an elec. current through the soln. a transportation of H_2O must take place in the direction of the anode or the cathode, according as the anion or the cation is the more strongly hydrated. As the detn. of the magnitude of this electrolytic transportation of H_2O is of great importance for the hydrate problem, a new method by which it may be detd. has been worked out. In this method the middle point of the electrolyte is fixed, and the volume change, which occurs at the electrodes on the passage of the current, is measured. The H_2O transported by electroendosmosis must be taken into consideration in this method. The values that have been obtained in this investigation for the transportation of H_2O cannot be explained on the assumption of electroendosmosis alone, but only when, in addition, it is assumed that H_2O is transported by the H_2O -enveloped ions. The H_2O transportation of a number of salts at different concns. has been detd. from the exptl. values, on the assumption that the sp. electroendosmosis is approx. independent of the concn. of the salt soln. The results obtained are in good agreement with those obtained by Washburn. From the values obtained for the transportation of H_2O , the true transport numbers for the different salts have been calcd. on the assumption that the exptl. transport numbers in gelatin do not deviate to any great extent from those which hold for aq. solns. By means of these true transport numbers, the hydration of a number of ions in 0.5 *N* soln. has been calcd. The results of this investigation furnish new evidence for the real existence of the hydration of ions. H. JERMAIN CREIGHTON.

The resistance of electrolytes. S. W. J. SMITH AND H. MOSS. Imperial Coll. Sci. *Proc. Phys. Soc. London* 25, 133-45(1913).—Expts. on KCl solns. showed that the resistance of the electrolyte was const. to 0.05% for currents of any frequency up to 2300 cycles. PAUL D. FOOTE.

Note on attainment of a steady state when heat diffuses along a moving cylinder. MISS A. SOMMERS. *Proc. Phys. Soc. London* 25, 74-6(1913).—Math. treatment of the problem of a column of Hg moving with uniform speed between two fixed temp. sources. An analogous problem would be the diffusion of a salt in soln. up a tube. PAUL D. FOOTE.

Heat transmission capacity of a silica dish. W. K. LEWIS. *J. Ind. Eng. Chem.* 7, 410-4(1915).—The heat transmission capacity consists of a conduction term proportional to temp. difference and a radiation term proportional to the difference of the 4th powers of the temp. The coefficients of these terms have been detd. and suggestions are made as to their application to problems in design and furnace construction. More work is to be done. I. MILLER.

The estimation of high temperatures by the method of color identity. CLIFFORD C. PATTERSON AND B. P. DUDDING. Nat. Phys. Lab. *Proc. Phys. Soc. London* 27, 230-62(1915).—Using a Lummer Brodhun photometer the light from incandescent

lamps is compared with that from a black body, by a color match instead of an intensity match. If the light from a non-black body is gray in the visible spectrum, *i. e.*, the radiation at any wave length is a const. factor of that from a black body at the same true temp., this method will give the true temp. of the non-black material in contrast to the apparent temp. obtained with an optical pyrometer. Measurements made upon W, C and Pt indicate that these materials are approx. gray in the visible spectrum. Values of the m. p. of Pt obtained by color matches of Pt against C and W lamps standardized for color gave 1750 and 1773° (in fairly good agreement with the latest accepted detns. of 1755 $\pm$ 5 by Waidner and Burgess and by Kanolt.—ABSTR.).

Electrolytic processes at diaphragms. II. The dependence of the magnitude and direction of the concentration changes and the water movement upon the hydrogen ion concentration. A. BETHE AND T. TOROPOFF. *Kiel. Z. physik. Chem.* 89, 597-637(1915); cf. C. A. 9, 992.—On the passage of an elec. current through an electrolyte, in which is placed a porous diaphragm (gelatin, white of egg, agar-agar, pig's bladder, collodium, wood, charcoal, gypsum) there occur at both sides of the diaphragm opposed concn. changes of all ions, and a displacement of the H₂O takes place. With all the above-mentioned materials, the magnitude of the concn. change and of the H₂O movement is dependent upon the H-ion concn. of the initial soln. With collodium, wood and charcoal there occurs only a change of magnitudes; the direction of the concn. change and of the H₂O movement always remains the same, the increase taking place on the negative side of the diaphragm and the H₂O moving with the positive current. With all the other materials investigated the direction changes. With high H concn., the concn. of all the ions increases on the positive side of the membrane and decreases on the negative side, and the H₂O moves with the negative current; on the other hand, the reverse occurs with low H concn. The position of the indifferent point varies with the nature of the ions present. Polyvalent anions displace it towards the acid side, while polyvalent cations displace it towards the alkali side. In general, however, it lies to the acid side of the neutral point. With increase in the neutral salt concn. of the initial soln. (NaCl) the concn. change (referred to the same quantities of elec.) becomes smaller, and the indifferent point (isoelectric point) is displaced towards the acid side. The magnitude of the concn. change increases with increase in the thickness of the diaphragm. Organic dyes have been found in these expts. to behave in the same way as true electrolytes. In order to explain the foregoing effects, it is supposed that the anions or cations enter the pores of the diaphragm and there experience a diminution of their mobility. The H₂O moves in the sense of the charge of the free mobile ions. The hydration of the ions plays a part in the movement of the H₂O, and in consequence of this the indifferent point of the H₂O movement does not coincide exactly with the isoelectric point. Equations have been developed to express the relation between direction and magnitude of the concn. change. Qualitatively, complete agreement has been found between the theoretical and exptl. results. If an electrolyte soln. is pressed through a diaphragm, it has been found that there occur opposed concn. changes of the ions on both sides of the diaphragm.

H. JERMAIN CREIGHTON.

Method of measuring the Thomson effect. H. REDMAYNE NETTLETON. Birkbeck College. *Proc. Phys. Soc. London* 25, 44-64(1913).—A method is derived math.

for measuring the Thomson effect by the temp. distribution in a conductor carrying an elec. current while the conductor moves uniformly through two fixed temp. sources. Using Hg, the "sp. ht. of electricity," σ , was observed to be -1.52×10^{-6} cal. per degree, per coulomb at 61° .

The electron theory of the optical properties of metals. I. G. H. LIVENES. Univ. Sheffield. *Phil. Mag.* 20, 655-72(1915).—A detailed analysis of the motion of the electrons in the metal along lines suggested by Thomson and Lorentz permits the formulation of a complete theory for the action of the most rapidly alternating fields in the metal. This theory is perfectly consistent with the special deductions given by Lorentz in the particular case of steady fields, and in this respect shows distinct advantage over the form of theory proposed by H. A. Wilson.

A. T. CAMERON.

A bolometric method of determining the efficiencies of radiating bodies. WM. A. BONE, H. L. CALLENDAR AND H. JAMES YATES. *J. Gas Lighting* 130, 72-4(1915).—The radiation falls from the fire upon one of two coils of platinum wire wound on a thin piece of mica for firmness and coated for constancy to an even surface with hard black enamel, the two coils being mounted back to back on either side of a circular gun-metal box, provided with water circulation and suitable covers for the coils, so that either coil can be exposed to radiation or screened. If one of the coils is exposed to radiation, a galvanometer shows a deflection proportional to the increase in resistance due to heating, and this serves as a measure of the intensity of the incident radiation. The const. of the bolometer can be readily detd. by comparison with a radio-balance. In obtaining the distribution factor, it appears from theory and observation that the sum of 4 readings taken at 60° along the equator and meridian of the radiation hemisphere of the gas fire together with the central reading, multiplied by $2\pi D/3$ gives as good an approximation to the total radiation as can be obtained by taking 81 readings. To keep const. the zero of the indicator, the temp. of the receiver must be maintained const. The value of this method for general work is increased by the fact that the instrument is of small size, light and without personal factor; the sensitiveness is variable over a wide range by varying the electric current employed for measuring the resistance; the readings are easily recorded automatically.

B. W. GRIMES.

Method of measuring the pressure of light by means of thin metal foil. GILBERT D. WEST. *Proc. Phys. Soc. London* 25, 324-30(1913).—The pressure of the radiation emitted by a C filament lamp at a distance of a few cm. is sufficient to cause a microscopically measurable deflection of the end of a suspended strip of Au or Al foil. The pressure observations agreed to 10% with the energy content per cc. as measured by the initial rate of rise of temp. of a Cu plate exposed to the radiation. P. D. F.

Ultraviolet excitation of the D line of sodium. R. J. STRUTT. Imp. Coll., South Kensington. *Nature* 95, 285-6(1915).—The secondary radiation of D light as emitted when Na vapor at a moderate temp. is illuminated by D light has been investigated in the case of the first ultraviolet line of the series which is situated at wave length 3303. It has been found that stimulation by this line likewise gives rise to D light. The chief essential in obtaining this result is a source giving a sharp line of great intensity at λ 3303. This was found in a Na vapor lamp in quartz analogous to the Hg lamps in general use. The visible light from such a lamp was filtered out by means

of a screen consisting of Co-blue uvioi glass, combined with nitrosodimethylaniline. The light which came through was photographed with a quartz spectrograph and was found to consist of λ 3303 exclusively. This radiation was concentrated by means of a quartz lens on a quartz bulb containing some Na. The bulb was made nearly red-hot with a Bunsen burner which was then extinguished. A patch of luminosity could be seen on the wall of the bulb when the ultraviolet beam fell upon it. As the bulb cooled and the vapor pressure of the Na diminished, this patch of light gradually expanded and filled the entire bulb; it then faded away and had disappeared when the bulb was cold in exactly the same way as is seen when D light is excited by the incidence of D light.

W. H. ROSS.

Ultraviolet excitation of the D line of sodium. R. J. STRUTT. *Nature* 95, 370 (1915).—Further investigations along the line referred to in the preceding abstr. has shown that stimulation of Na vapor by one member only of the ultraviolet doublet at wave length 3303 results in an emission of both components of the D line in about equal intensity, and not of the corresponding member only of the D line as might have been expected.

W. H. ROSS.

The widening of spectrum lines. LORD RAYLEIGH. *Phil. Mag.* 29, 274-84 (1915).—The causes which interfere with the abs. homogeneity of spectrum lines are (1) the translatory motion of the radiating particles in the line of sight, operating in accordance with Doppler's principle, (2) a possible effect of the rotation of the particles, (3) disturbance depending on collision with other particles either of the same or of another kind, (4) gradual dying down of the luminous vibrations as energy is radiated away, (5) complications arising from the multiplicity of sources in the line of sight (this cause of widening cannot act alone, but merely aggravates the effect of the other causes). The first cause is the more important in many cases, especially when vapors in a highly rarefied condition are excited electrically. The paper consists of a mathematical discussion of the bases for this list of causes. Exptl. evidence is quoted to show that the light of a powerful Na flame is due much more to the widening of the spectrum lines than to an increased brightness of their central parts.

A. T. C.

Effect of pressure upon arc spectra. V. Nickel, λ 3450 to λ 5500. W. G. DUFFIELD. *Trans. Roy. Soc. London (A)* 215, 205-52 (1915); cf. *C. A.* 2, 363; 5, 238. —The app. has been described in previous papers. The arc was formed of rods enclosed in a steel cylinder. The second-order spectrum was used, the dispersion being 1.3 Å. per mm. Increase of pressure was obtained by admitting air to the cylinder. This increased the intensity of the arc, but photometric measurements could not be made on account of its unsteadiness. Photographs were taken at 10 to 100 atms. for λ λ 3450 to 4050, at 10 pressures between 10 and 200 atms. for λ λ 4050 to 4600, 10 to 100 atms. for λ λ 4600 to 5120 and at 10, 20 and 75 atms. for λ λ 5120 to 5500. Some of the exposures are the resultant of a large number of short-lived arcs, as the arc had to be re-struck frequently. Some of the lines broaden nearly symmetrically, but most lines broaden unsymmetrically. A few lines showed strong reversal, others only a weak tendency to reverse under pressure. The spectrum did not become continuous with great pressure as in the case of Ag. Details of the expts. are shown in many tables and full-size reproductions of the photographs. An account of the rate of displacement with wave length, of the relation between displacement and pressure, of the influence of the density of the material and of the intensity of the spectrum lines upon the displacement and of the resolution of the Ni spectrum into groups of lines has also been given.

E. B. MILLARD.

Rotation dispersion of homologous series. AUG. HAGENBACH. *Basel. Z. physik. Chem.* 89, 570-96 (1915).—If α represents the rotation for different wave lengths λ , then the rotation dispersion of a substance may be expressed by the function φ ,

so that $\alpha = \phi(\lambda)$; while the dispersion for homologs of the substance may be expressed by the equation $\alpha = C\phi(\lambda)$, where C , the sp. factor, has a different value for different substances, but for a particular substance is const. for all values of λ ; that is, the sp. factors are the sole characteristics whereby the dispersions of the different members of a homologous series are differentiated, and, therefore, C depends on the chem. constitution of the individual member of the series. By calcg. the difference between two α , $\alpha_A - \alpha_C$, for the different members of a series, values are obtained for α_0 which all belong to one and the same wave length λ_0 . By means of this wave length the different homologous series may be differentiated from one another. The function ϕ in the above equation has not yet been accurately ascertained. It has been shown that $\alpha = A + B\nu^2$, and that $\alpha = A\nu^2 + B\nu^4$, where $\nu = 1/\lambda$. Where the first of these equations holds, straight lines which start from a point on the abscissa are obtained, when α is plotted as a function of ν^2 . The relation $C = \alpha'/\alpha = A'/A = B'/B$ has been confirmed. In conclusion, it is pointed out that the expression derived for the rotation dispersion for the members of homologous series is analogous to the Ramsay and Young rule for the b. p. of members of homologous series. H. J. C.

Density of liquid hydrogen, index of refraction and dispersion of liquid hydrogen and liquid nitrogen. HERBERT AUGUSTIN. Leipzig. *Ann. Physik* 46, 419-45(1915).—The displacement method has been so refined that an accuracy of 0.8-0.9% could be attained. The mean value at 745.52 mm. and -252.83° was $d = 0.07105$ for liquid H, in agreement with the value 0.07093 of Onnes and Crommelin (*C. A.* 8, 2096). Wiedemann's total reflection method has been used for detg. n over the range $\lambda = 656.3 \mu$ to $\lambda = 404.7 \mu$, with an accuracy of about 0.2% for $(n - 1)$. A double-walled vacuum flask with sealed-in plane windows was used for these expts. and those on liquid N. The data were used to calc. the Wiener formula number (*Ber. K. Säch. Ges. Wiss., Math.-phys. Kl.* 62, 256), from which it appeared that the H mol. was spherical and the N mol. nearly so. A rigorous theoretical proof has not been attempted. E. B. MILLARD.

Photoelectric constant and atomic heat. T. C. SUTTON. Univ. Melbourne. *Phil. Mag.* 29, 734-6(1915).—The product of the at. heat and the photo-elec. const. for a large number of metals is a number close to 35.5. It is suggested that both phenomena are due to the ultimate discontinuity of energy as postulated in the quantum theory. When a limited number of quanta are absorbed by a mol., the various properties of the molecule are not necessarily affected to the same extent; some quanta may function in one way, some in another. For any particular metal the proportion that affects the at. heat is related to that which affects the photo-elec. const. If the nature of the metal is changed this relation is one of inverse proportion. The results suggest that the divergences of the values of the photo-elec. const. from the value of one quantum, 6.6×10^{-27} , are due to the work done in changing the amplitude of swing of the newly charged atoms left within the metal. A. T. CAMERON.

Kinetics of photochemical reactions. D. BERTHELOT. *Compt. rend.* 160, 519-22 (1915); cf. *C. A.* 5, 2460.—From the equations $1/2mv^2 = sT$ and $v = (2sT/m)^{1/2}$, B. calcs. that the entropy of a single atom (the quantum of entropy) is 2×10^{-18} c. g. s. units and that the speed of a H mol. at 0° is 185000 cm. per sec., that of O_2 is 46000 cm. per sec., and that of Hg atoms is 18500 cm. per sec. Under the influence of violet light $\lambda = 0.4 \mu$, $N = 7.5 \times 10^{14}$, electrons are projected with a velocity of 1070 km.

per sec., and under light of 0.2μ wave length the speed is 1510 km. per sec. Other calcns. are also given.

E. B. MILLARD.

Production of rare gases in vacuum tubes. R. H. GODDARD. *Science* 41, 682-4 (1915).—Discharges in vacuum tubes give rise to Ne and He, which are not accompanied by A, showing that the gases are not due to leaks in the app. To show that the gases are occluded in the electrodes, an app. similar to that of Winchester (*C. A.* 8, 2520) has been designed in which the Al electrodes can be cleaned mechanically on all sides while in the vacuum tube. By cleaning them in O, it should be possible to demonstrate the formation of He and Ne from O if it exists.

E. B. MILLARD.

The spectrum from mercury vapor in an electric field. C. D. CHILD. *Colgate Univ. Phys. Rev.* 4, 387-90(1915).—C. places a wire gauze, which fills the cross section, in the condensing tube of a Hg arc. The arc is placed in series with a dynamo and a resistance. The potential of the gauze can be varied by moving a contact along the resistance. When the potential of the gauze is about 10 v. above that of the middle of the arc, it is found that the luminosity is diminished, or entirely destroyed if the amt. of vapor is not too large. A further increase of the potential of the gauze increases the luminosity, and the color changes from a reddish to a greenish tint. While this change is taking place, but with a field too weak to increase the intensity, the yellow lines and the greenish blue line are not so bright as the green while the others of that series are distinctly brighter. With a stronger field all of the lines become brighter but the change in the green and the violet is greater than in the yellow. This may be explained by assuming that certain lines are produced by the union of electrons with positive ions which lack one electron, while other lines are produced by the combination of electrons with positive ions lacking more than one electron.

Lead and the end product of thorium. II. A. HOLMES AND R. W. LAWSON. *Phil. Mag.* 29, 673-88(1915).—In addition to the material given in previous publications (*C. A.* 8, 1912; 9, 266, 1147), the paper contains a discussion of the ages of minerals as corrected by at. wt. detns. of the Pb contained. The evidence of at. wt. detns. of Pb extd. from radioactive minerals points to the stability of Ra G, and the instability of Th E.

A. T. CAMERON.

The absorption of homogeneous beta rays. R. W. VARDER. Univ. Manchester. *Phil. Mag.* 29, 725-33(1915).—Expts. were made to investigate as accurately as possible the form of the ionization absorption curve when very homogeneous β -rays pass through a standard substance like Al, and also to test whether there is any simple relation connecting the absorption with either the velocity or energy of the β -particle. A pencil of homogeneous rays was obtained from the magnetically deflected rays from Ra Em. The curve of β -ray absorption for Al shows, after a small thickness of matter has been traversed, an approx. linear relation. The results for other material such as paper, Sn, Pt, do not show this linear relationship which is shown to be due to a chance balancing of the opposing effects of scattering and diminution of velocity. If there were no scattering nor straggling the curve should be similar in shape to a Bragg α -ray curve.

A. T. CAMERON.

The absorption in lead of the gamma rays emitted by radium B and radium C. H. RICHARDSON. School of Technology, Manchester. *Proc. Roy. Soc. London (A)* 91, 396-404(1915).—A detn. and analysis were made of the absorption curves in Pb of the radiations emitted by Ra B and Ra C. In addition to the penetrating type of radiation for which $\mu = 0.5$ (cm.⁻¹) in Pb, Ra C has been found to emit soft types for which $\mu = 46$, $\mu = 6.0$ and $\mu = 1.5$, and which are practically absorbed by 1.5 cm. of Pb. The analysis of the Ra B absorption curve shows that in addition to the radiation $\mu = 40$ in Al, the rays emitted consist of 3 types for which $\mu = 46$, $\mu = 6.0$ and $\mu = 1.5$ for Pb. The close similarity of this latter radiation with that of the soft portion emitted by Ra C, already observed by Rutherford and Andrade (*C. A.* 8, 3754), has been established. The absorption of the radiations in different elements has been examd., and the bearing of the results discussed. No evidence of anomalous absorption has been found in the case of the penetrating radiations.

W. H. ROSS.

Absorption experiments with radioelements. KARL HOROVITZ AND FRITZ PANETH. Vienna. *Z. physik. Chem.* 89, 513-28(1915).—Expts. have been carried out to ascertain the adsorption of radioelements by difficultly sol. salts and oxides. It has been found, as a rule, that the adsorption of each radioelement by a substance is good, when the analogous compd. is difficultly sol. in the solvent employed. By analogous compd. is meant the compd. of the radioelement with the electronegative constituent of the adsorbent. The action of the adsorbent is most powerful when an acid with the same anion is employed as solvent. This phenomenon probably is due to the diminution of the solubility of the adsorbent and the analogous compd. of the radioelement. Just as H₂SO₄ increases the adsorption by sulfates, and HCl the adsorption by chlorides, HNO₃ appears to favor the adsorption by oxides. Small differences in the prepn. of the adsorbent often appreciably change the character of the adsorption. This may be due to the differences in the surfaces of the two prepn., or to the chem. compn. of the surfaces. By means of the results obtained in this investigation, it is possible to explain the often unexpected, sharply defined chem. behavior of the radioelements in pptn. reactions.

Model for illustrating Röntgen ray interference phenomena (HAUER) 1.

KAILAN, A.: Ueber die chemischen Wirkungen der durchdringenden Radiumstrahlung. Wien: A. Hölder. 29 ss. 85 Pf.

U. S., 1,142,153, June 8. E. EBLER. Obtaining radioactive compounds from solutions by adsorption. A soln. containing Ba and Ra chlorides is treated with pptd. hydrated MnO₂ and the solid products, after sepn. of the soln., are treated with hot

HCl to dissolve the adsorbed radioactive substances. HCl gas, or HNO_3 , ppts. a concd. Ra compd. from this soln., and the process may be repeated to effect further concn.

U. S., 1,142,154, June 8. E. EBLER. Radioactive ores or other mixts., containing Ra, Meso-Th, Th, etc., are mixed with CaC_2 and Ca hydride and the mixt. is ignited to prepare the material for extn. and concn. with HCl as in the preceding pat.

Brit., 2,629, Jan. 31, 1914. J. LANDIN. Rendering water and other liquids radioactive by treating them with a radioactive prepn. in which the radioactive salt, etc., either a solid or in soln., is enclosed within a non-porous organic liquid or solid medium which is capable of transmitting the emanations, but which is itself not affected by the liquid to be rendered radioactive so that the active salt, etc., is protected against its action. Thus, a solid Ra salt may be well stirred with paraffin oil, gasoline, or CS_2 , and the mixt. introduced into a porous clay or kieselguhr cylinder, which is placed in the liquid to be treated; or the solid Ra salt may be incorporated in a covering of solid paraffin, or wax, and the porous cylinder dispensed with. When a soln. of a Ra salt is used, this may be enclosed in a hollow body of paraffin, or it may be emulsified with melted paraffin. The process is applicable to the treatment of milk, beer, juices and oils, in addition to H_2O .

Ger., 279,029, Apr. 18, 1914. VEIHA-WERKE, VEREINIGTE ELEKTROTECHNISCHE INSTITUT FRANKFURT-ASCHAFFENBURG M. B. H. and F. DESSAUER. Röntgen screen consisting of transparent or translucent material with fluorescing bodies distributed in the mass.

Ger., 279,956, Nov. 30, 1913. KUNHEIM & Co. A Ra-Th prepn. suitable for use in obtaining thorium-X solution. Instead of the NH_4OH used heretofore for the pptn., pure H_2O_2 is used to sep. the Ra and Th from purified neutral solns. which have been obtained by pptg. the crude solns. of matured Meso-Th preps., or mother liquors from the recovery of Meso-Th, with $\text{Ba}(\text{OH})_2$, and extg. with concd. H_2SO_4 . The solns. must still contain small amts. of the rare earths. By the addition of H_2O_2 , all the Ra and Th, together with the small amts. of rare earths present, are sepd. as perhydroxide in the form of a ppt. which may be filtered and extd. The Th-X formed is readily and completely dissolved out from the perhydroxide ppt. by means of dil. NaCl soln. Preferably, the app. specified in 247,491 is used.

Ger., 280,694, Jan. 10, 1914. H. STERN. Obtaining radioactive constituents from liquids containing them by means of natural or artificial zeolites, or the like, with which the Ra compds. enter into double decompn. The reacting mass is formed as a filter through which the radioactive liquids are conducted. The alkali zeolites are preferred. The filter material, containing the Ra in chem. combination, may in certain circumstances be employed directly. However, from this material, by the use of suitable acids or salt solns., the radioactive substance can be dissolved out in concd. form, e. g., when zeolites have been used, by means of HCl or NaCl soln. In the latter case the zeolite is regenerated and returned to the process. From the concd. Ra soln. the radioactive substance can be isolated, as by pptn. as the sulfate. While in contact with the zeolites, the waters may be treated by the addition of alk. earth hydroxides, whereby the sepn. of the radioactive substances can be accomplished more readily and quickly.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Passage of electricity through metals. J. J. THOMSON. *Electrician* 75, 274 (1915).—An address. C. G. F.

Improved laboratory furnace. C. M. JOHNSON. *Iron Trade Rev.* 56, 613-4 (1915); illus.—For 220 v. 85-90 ft. of 20-gage (mm. diam.) nichrome wire is encased in alundum cement and surrounded by a split infusorial earth muffle. The cost is about \$10. H. V. MAIN.

Electric steel in Germany and Austria. ANON. *Met. Chem. Eng.* 13, 398(1915).—Germany produced 89,336 tons and Austria 19,844 tons during 1914. W. H. B.

Sublimation and distillation of aluminium nitride. F. FICHTER AND G. OESTERHELD. Basel. *Z. Elektrochem.* 21, 50-4(1915); cf. C. A. 7, 2905, 3282.—The app. has been described previously (C. A. 7, 2727). AlN begins to sublime in a W tube at about 14 mm. pressure of N at $1870^{\circ} \pm 20^{\circ}$, and sublimes completely at $1890^{\circ} \pm 20^{\circ}$. The evapn. was accompanied by a partial dissociation into the elements; and some Al was found with the sublimed AlN in the cooler parts of the tube. In a 2 mm. H vacuum the dissociation was complete. No results could be obtained with a W tube at high temp., on account of the action of W with N. Expts. in graphite and C tubes with N at atm. pressure showed sublimation without the formation of metal, but the sublimate was contaminated with C particles and carbide. Al_4C_3 dissociates partly when heated to 2000°, leaving a graphitic residue in the vacuum tube. Fine gray AlN could be prepd. by using Al electrodes for an arc in an atm. of N, and freeing the powder from metal by distn. in dil. H at 1840° . The results are not completely in harmony with those of J. Wolf (C. A. 8, 626, 1915, 2853). E. B. MILLARD.

The corona produced by continuous potentials. L. W. CHUBB, *et al.* *Proc. Am. Inst. Elec. Eng.* 34, 1323-8(1915).—Discussion of Farwell's paper (C. A. 9, 1425). C. G. F.

It resists action of weak alkalis, neutral solns. and strong and dil. acids. Tests show unusual impermeability and low resistance. It is manufactured by General Filtration Co., Rochester, N. Y.

W. H. BOYNTON.

Storage battery voltage regulation. C. S. REDDING. *Elec. World* 65, 1134(1915).—A sensitive detector (regulating element) actuates a double relay which operates a series rheostat in the main battery current. Directly across the battery and control rheostat is connected a regulating element. The cell is so connected that e. m. f. opposes that across a resistor equal to that of a Weston standard cell. When e. m. f. across the battery changes, the drop across the resistor changes with a resulting flow of energy through the galvanometer, causing a deflection. This actuates the restoring

mechanism, causing the circuit to be closed, as the relay operates the motor and changes the position of the contact on the control rheostat. The time the relay remains closed depends upon the amt. the arm is displaced, which depends upon the galvanic deflection. The app. operates on potentiometer or Wheatstone bridge circuits.

W. H. BOYNTON.

Charging small storage batteries. G. E. MILES. *Power* 41, 757(1915).—The battery is in series with the generator-field with a rheostat regulating the current through the battery. The battery should be disconnected before shutting down the charging machine to prevent discharge through the exciter-armature and polarity reversal. The only wasted energy is that taken by the rheostat and it depends upon the ratio of the current required for charging to that passing through the exciter-circuit.

W. H. BOYNTON.

Lead poisoning in the manufacture of storage batteries. A. HAMILTON. U. S. Bur. Labor Statistics, *Bull.* 165, 38 pp. (11 plates).—Processes in the making of storage batteries, hygienic conditions, wages, and Pb poisoning in the industry are discussed. The British regulations and the general provisions of the French law governing the manuf. of elec. accumulators are given. *Summary:* In the prepn. of the Pb plates and grids the workmen are exposed to the danger of Pb poisoning through Pb and Pb oxide dust and through fumes from melted Pb. In making and applying the paste the danger of poisoning is still greater. These dangers can be obviated by installing hoods and exhausts to carry off fumes and dust, by substituting machine for hand work, by providing ample washing facilities for the workmen, and insisting on strict cleanliness on their part, by providing a sep. lunch room as the only place where food may be kept and eaten, and by keeping the premises where the work is carried on clean and free from dust. Thorough medical supervision should be compulsory to detect and eliminate those who are oversusceptible to Pb, to discover cases in early stages, educate workmen, etc. The rate of Pb poisoning in the largest German factory in 1912 was 0.97 per 100 employed; in Great Britain for all factories in 1912 the rate was 3 per 100. In the U. S. the 5 largest factories were employing (1913) about 915 men in work which exposed them to Pb; rate of poisoning = 17.9 per 100. The largest proportion of Pb poisoning occurred among the men handling Pb oxides, lowest among those handling metallic Pb only. Most of the employees are of foreign birth, speak no English, and are ignorant of the dangers of the work or do not know how to protect themselves against it. The difference between the U. S. rate of poisoning and the British and German rates is attributed to the better standards of sanitation and management in the 2 European countries. The 3 states in which the 5 largest U. S. factories are situated have already passed laws which provide safeguards for the men engaged in Pb industries; if strictly enforced, our percentage of Pb poisoning is bound to fall.

F. W. SMITHER.

Preventing corrosion from electrolytic action. ANON. *Power* 41, 740(1915).—As a means of preventing electrolytic corrosion of boilers and similar vessels, the Cumberland Eng. Co., London, Eng., has developed the following app.: Insulated bolts connected to the boiler shell form the anode, while the shell itself is the cathode. A low tension current, from 6 to 10 v., regulated by fixed resistances, is used. H_2O is dissociated, a H_2 film forming over the immersed portion of the shell, thus protecting it; the acid radicals pass to the Fe anodes, which become reduced and must be renewed from time to time.

I. C. MATTHEWS.

Electrolytic insulation of aluminium wire. C. E. SKINNER AND L. W. CHUBB. *Trans. Am. Electrochem. Soc.* 26, 137-47(1914); *Met. Chem. Eng.* 12, 712-3(1914); *Elec. World* 64, 766(1914).—A smooth, iridescent or abrasive and white coating of Al_2O_3 is deposited upon Al wire by passing Al wire first as cathode through a tank con-

taining either a soln. of borax, NH_4 borate, or Na silicate, then through another tank in which the wire is made anode. Two wires so treated, when twisted together, will stand a pressure of from 200 to 500 v. before short circuiting through the film. It is recommended that a high c. d. be used and the voltage brought up quickly. The film coating varies from 0.0001 to 0.0004 in. in thickness, and will stand sharp bends without serious deterioration. Drawings of the app. used are given; it consists of a simple series of tanks and means for passing the wire through them on rolls and reels. Square wires are likely to be defective when so treated, owing to the sharp corners.

Silver fluorides. A. GUNTZ AND A. A. GUNTZ, JR. *Ann. chim.* 2, 101-32(1915).—A more detailed account of work already published (see C. A. 8, 2124). W. H. S.

Calcium amalgams. L. CAMBI AND G. SPERONI. Milan. *Atti accad. Lincei* 23, II, 599-605(1914).—The literature on amalgams is reviewed carefully. In the system Ca-Hg it was shown by thermal analysis that the compd. CaHg₂ occurs up to 33 atoms

% Ca. CaHg_4 melts with decompn. at 266° . At higher temps. there is probably a primary sepn. of CaHg_3 . Mixts. containing more than 14 at. % Ca do not melt completely at ordinary pressure and b. 377° . Thermal analysis, however, does not give any evidence for the existence of compds. with a higher Hg content, such as have been frequently reported. Similar results were obtained for the systems Na-Hg and K-Hg.

E. J. WITZEMANN.

Mercurial compounds of aliphatic amines. M. RAFFO AND A. SCARELLA. Univ. Bologna. *Gas. chim. ital.* 45, I, 123-7(1915).—The prepn. of a number of aliphatic amines analogous to mercuriammonium salts by reactions similar to those by which the corresponding ammonium salts are obtained is described. The structure of the resulting compds. is interpreted according to the Rammelsberg-Pesci formulation. A soln. of $\text{Hg}(\text{NO}_3)_2$ treated with agitation with a slight excess of a MeNH_2 soln. gave a white ppt. which after warming on the H_2O bath settled as a white microcryst. powder. The *mercurimethylammonium nitrate*, MeNHg.HNO_3 , thus obtained is insol. in H_2O and ordinary solvents; heated dry it deflagrates without melting. *Mercuriethylammonium nitrate*, EtNHg.HNO_3 , was similarly obtained as small rhombic laminas; its properties are also similar. Adding gradually EtOH soln. of amylamine to a concd. $\text{Hg}(\text{NO}_3)_2$ soln. with const. agitation and keeping the soln. acid gives a white microcryst. ppt. of *mercuriamylammonium nitrate* with *amylamine nitrate*, $\text{C}_5\text{H}_{11}\text{NHg.HNO}_3$, $\text{C}_5\text{H}_{11}\text{NH}_2$, HNO_3 , insol. in H_2O and ordinary solvents. This product washed with a 2% NaHCO_3 soln. and then with H_2O and finally EtOH , eliminated amylamine nitrate and the HNO_3 besides and left only *mercuriamylamine*, $\text{Hg:NC}_5\text{H}_{11}$, white powder, insol. in H_2O and solvents. MeNH_2 in conc. soln. added slowly to a soln. of HgCl_2 slightly acid with HCl ppts. *mercurimethylammonium chloride*, MeNHg.HCl , white, microcryst. ppt., insol. in H_2O , EtOH and Et_4O .

E. J. WITZEMANN.

Action of carbon dioxide on inorganic sulfides. N. COSTRANU. *Ann. chim.* 2, 189-210(1915); cf. C. A. 8, 636.—Sulfides decomposable by H_2O such as those of Si and B and sulfides insol. in H_2O such as ZnS and Cu_2S act as reducing agents when heated in an atm. of CO_2 , CO being formed. S is set free and the sulfide converted to oxide. Other insol. sulfides when heated in CO_2 suffer no change but act as if heated in a vacuum. Sometimes the sulfide is changed from the amorphous to the cryst. state at suitable temps. The alkali sulfides, heated in CO_2 , are changed to carbonates, CO , COS , and free S being produced. The free S reacts with some of the carbonate, alkali pentasulfide and sulfate being formed and CO_2 regenerated.

The noble metals in litharge. J. LÖRBY. *Chem. Ztg.* 39, 287(1915).—The author obtained weighable amts. of Au and Ag from 1200 g. of "C. P." PbO furnished him by a Frankfurt firm.

H. L. OLIN.

Critical examination of tungstic and tungsto-chromic compounds. V. K. KANCHEV. *J. Russ. Phys. Chem. Soc.* 46, 729-42(1914).—Knorre's method for detg. W (Ber. 38, 783(1905)) is tedious. A quick volumetric method, exact to within 0.1%, is proposed, based upon the hydrolysis of benzidine salts, making it possible to titrate their acid as if it were free. The method is as follows: To the warm soln. of the W salt add an excess of a soln. of the colorless HCl salt of benzidine, collect the ppt. produced on a filter and wash with a little H_2O . Transfer the ppt., together with the filter, to an Erlenmeyer flask, add H_2O and after warming the mixt. to 60° , titrate the acid with 0.1 N NaOH , using phenolphthalein as indicator and increasing the heat to 100° at the end of the titration. With the aid of this method several salts described in the literature were examd. The results may be summed up as follows: Lefort's Na di- and tritungstates, $\text{Na}_2\text{O} \cdot 2\text{WO}_3 \cdot 6\text{H}_2\text{O}$ and $\text{Na}_2\text{O} \cdot 3\text{WO}_3 \cdot 4\text{H}_2\text{O}$ (*Ann. chim. phys.* [5] 9, 93) and Ca and Ba ditungstates, $\text{CaO} \cdot 2\text{WO}_3 \cdot 3\text{H}_2\text{O}$ and $\text{BaO} \cdot 2\text{WO}_3 \cdot \text{H}_2\text{O}$ (*l. c.* 15, 325) do not exist, the compds. obtained by strictly following L.'s directions being either

identical with or mixts. of other known salts. Pure chromotungstates (e. g., $\text{Cr}_2\text{O}_3 \cdot 7\text{WO}_3 \cdot 9\text{H}_2\text{O}$) are obtainable only by using the violet modifications of the salts of trivalent Cr, the compds. resulting when the green modifications are used always containing more or less basic salts. This is due to the difference in comp. of the ions of the 2 varieties of Cr salts, the violet modifications giving simple Cr ions, while the green give complex ions (Whitney, *Z. physik. Chem.* 20, 41). L.'s salts, $\text{Cr}_2\text{O}_3 \cdot 3\text{WO}_3 \cdot 3\text{H}_2\text{O}$, $\text{Cr}_2\text{O}_3 \cdot 4\text{WO}_3 \cdot 6\text{H}_2\text{O}$ and $\text{Cr}_2\text{O}_3 \cdot 5\text{WO}_3 \cdot 5\text{H}_2\text{O}$, do not exist, the first being $\text{Cr}_2\text{O}_3 \cdot 7\text{WO}_3 \cdot 16\text{H}_2\text{O}$, while the other 2 are indefinite mixts., colored green by contamination with the green modification of Cr salts. In warm solns. containing paratungstates and salts of trivalent Cr all of the paratungstic acid cannot be set free by the addition of a mineral acid, and therefore cannot be quantitatively detd. by means of benzidine salts, because in such solns. the W is in the form of complex W-Cr acids. These will be reported upon in the near future.

H. M. GORDIN.

Hydrates of uranyl nitrate. DE FORCRAND. *Ann. chim.* 3, 5-48(1915).—From the results of previous investigators (cf. *C. A.* 4, 887; 5, 2374; 6, 3374, 3376), F. concludes that a marked similarity exists between the nitrates of UO_2 and Cu and that the formation of H_2UO_4 and loss of HNO_3 upon heating the 3- or 2-hydrate is analogous to the formation of basic Cu nitrate; $(\text{NO}_3)_2\text{UO}_2 + n\text{UO}_2(\text{OH})_2$ and $(\text{NO}_3)_2\text{Cu} + 3\text{Cu}(\text{OH})_2$. The reactions during dehydration might be considered as (A) the simple dehydration which according to the data of Marketo absorbs 29.9 cal., and (B) more complicated and including (A), which might be formulated: $\text{N}_2\text{O}_8\text{UO}_2 \cdot 2\text{H}_2\text{O}$ solid = $\text{N}_2\text{O}_8\text{UO}_2$ solid + $2\text{H}_2\text{O}$ gas — 29.9 cal.; $\text{N}_2\text{O}_8\text{UO}_2$ solid = N_2O_8 gas + UO_2 solid = x ; N_2O_8 gas + H_2O gas = $2\text{NO}_2\text{H}$ + 10.8 cal.; UO_2 solid + H_2O gas = UO_2H_2 solid = y ; H_2UO_4 solid + $\text{N}_2\text{O}_8\text{UO}_2$ solid = basic nitrate = q . The thermochem. data are lacking but by analogy with Cu should approximate $x = -32.6$; $y = +17$; $q = +4.03$. The necessary data were detd. exptly. and found: for (A), —33.27; x , —30.6; y , +14.62; q , +4.03 cal. The sum of the partial heats of (B) is —1.15 cal., insignificant in comparison with (A) (—33.27). It follows that the temp. limits t_a and t_b of the 2 reactions lie so near each other that practically it is impossible to produce (A) without (B) also taking place. The following exptl. results and data are presented: (1) dehydration of 6-hydrate at room temp. and atm. pressure over H_2SO_4 gives 2-hydrate only after 30 days; the 3-hydrate (approx.) after 3 days but no abs. sepn. of the 2 phases; marked retardation of rate of dehydration near the 3-hydrate. (2) Same *in vacuo* (4–5 mm.), 3.454 mols. H_2O removed in 1 day; 4 mols. after 9 days. (3) Dehydration of 2-hydrate in current of CO_2 , (a) at 160° , dehydration complete after 3–4 hrs.; much loss of HNO_3 ; (b) at 125 – 130° , approx. 1 mol. H_2O lost after 4–5 hrs. if HNO_3 loss detd. and corrected for; const. wt. after 55–60 hrs.; product = $\text{N}_2\text{O}_8\text{UO}_2 + \frac{1}{11} \text{H}_2\text{UO}_4$; (c) at 98 – 99° , 1 mol. H_2O removed after 150 hrs.; residue then $\text{N}_2\text{O}_8\text{UO}_2 \cdot \text{H}_2\text{O} + \frac{1}{16} \text{H}_2\text{UO}_4$. This expt. fixed the location of t_a and t_b and served to isolate the previously unknown *monohydrate*. (4) Dehydration of the 2-hydrate in a current of CO_2 charged with HNO_3 vapors (a) at 165° , after 15 hrs., $\text{N}_2\text{O}_8\text{UO}_2 + \frac{1}{28} \text{H}_2\text{UO}_4$; (b) at 155° , after 30 hrs., $\text{N}_2\text{O}_8\text{UO}_2 + \frac{1}{31} \text{H}_2\text{UO}_4$. By this method a practically pure anhydrous salt should be obtained at 125° . The thermochem. data were obtained by dissolving the various hydrates thus prepd., of which the actual comp. was 5.975 H_2O , 2.85–2.90 H_2O , 2-hydrate pure, 1-hydrate with $\frac{1}{16} \text{H}_2\text{UO}_4$ and anhydrous salt with $\frac{1}{28} \text{H}_2\text{UO}_4$, the necessary corrections for comp. being made. Heats of soln.: 6-hydrate, —5.45 cal.; 3-hydrate, +1.35; 2-hydrate, +5.05; 1-hydrate, +11.87; 0-hydrate, +19.00. Effluorescence pressure = 1 atm. at: 1-hydrate, 292° ; 2-hydrate, 281° ; 3-hydrate, 176° ; 6-hydrate, 128° . Heat of soln., of UO_2 (prepd. at 290 – 300°) 19.803 cal.; of $\text{UO}_2 \cdot \text{H}_2\text{O}$, 14.846; of $\text{UO}_2 \cdot 2\text{H}_2\text{O}$, 12.375; for heats of hydration, 1st mol. H_2O , 4.957 cal., for 2nd mol. 2.471 cal. Heat of formation of $\text{UO}_2(\text{NO}_3)_2$ solid = 67.25; dissolved = 86.25,

as compared with nitrates of Cu, 71.49 and 81.96, Ni, 100.12 and 111.94; Mn, 133.77 and 146.7. An explanation is appended of the fact noted by Mailhe that addition of the blue hydrate of Peligot, $\text{CuO} \cdot \text{H}_2\text{O}$, to a not too concd. soln. of $\text{UO}_2(\text{NO}_3)_2$ causes CuO to displace UO_2 , the latter pptg. out. $\text{UO}_2 \cdot \text{H}_2\text{O}$ and $\text{CuO} \cdot \text{H}_2\text{O}$ dissolved in HNO_3 liberate nearly the same heats, 14.84 and 14.72. Both dissolve in solns. of their nitrates to form basic salts. When $\text{CuO} \cdot \text{H}_2\text{O}$ is added to a soln. of $\text{UO}_2(\text{NO}_3)_2$, HNO_3 is partitioned between the 2 bases; then $\text{UO}_2 \cdot \text{H}_2\text{O}$ solid + H_2O liquid = $\text{UO}_2 \cdot 2\text{H}_2\text{O}$ solid + 2.471 cal. $\text{CuO} \cdot \text{H}_2\text{O}$ has a small heat of form, and forms no 2-hydrate. A. R. M.

Reaction between ferrous oxide and carbon and between carbon monoxide and iron. V. FALCKE. *Z. Elektrochem.* 21, 37-50(1915).—The author has studied these reactions at temps. ranging from 600° upward, and has examd. the gaseous products obtained when the reaction mixts. were dissolved in HCl . Three varieties of graphite and 5 of amorphous C were used. After thorough purification these were analyzed and their ds. detd. The app. was one used in previous work (*Ber.* 46, 743-50(1913); cf. *C. A.* 7, 2525). The solid mixts. were introduced in the form of compressed pellets. Below 650° the highly purified varieties of C do not react with FeO and above this temp. the several varieties of C do not behave alike and may be classed in 3 groups. Sugar charcoal and that obtained by the action of CO on Na are quite inactive up to 800° . C obtained by burning C_2H_2 in Cl and that from petroleum reacted with vigor at 650° . It is not known whether the difference in behavior is a property of the different modifications or the result of catalytic action. The graphites reacted vigorously also. The products of the reaction of C and FeO contained pure Fe , and no hydrocarbons resulted from soln. in HCl . When Fe was permitted to absorb a large quantity of CO and the equil. pressure set up at 600° , the product of the reaction which took place yielded large amts. of satd. hydrocarbons, chiefly ethane, when treated with HCl . No solid C remained. On the contrary when Fe was heated in a stream of CO or allowed to absorb CO in large amts., and then heated in a vacuum, the product treated with HCl gave no hydrocarbons and a residue of C resulted. W. H. S.

Catalytic action of colloidal metals of the platinum group. XI. Reduction of molybdic acid. C. PAAL AND H. BÜTTNER. *Univ. Leipzig. Ber.* 48, 220-3(1915); cf. *C. A.* 1, 2851; 2, 2932, 2933; 3, 2158, 2159, 2455; 4, 314; 7, 2569.—In a previous article (cf. *C. A.* 8, 3275) it is stated that solns. of $(\text{NH}_4)_4\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$ are reduced by H in presence of colloidal Pd to $\text{Mo}(\text{OH})_4$. The same catalyst in a more active condition has been used in the present work. The reduction is complete at ordinary temps., but at 50 - 60° H is absorbed anew particularly under slight pressure, and then insol. $\text{Mo}(\text{OH})_3$ is formed as a black sludge. W. H. S.

7. ANALYTICAL CHEMISTRY.

H. G. R. ARDAGH.

Application of spectrography to analytical and industrial chemistry. S. J. LEWIS. *Analyst* 40, 188-9(1915).—L. gives a general discussion of the subject and recommends increased use of the spectrograph in analysis and chem. industry. P. B. D.

The volume of liquids titrated at different temperatures. H. PELLET. *Ann. chim. anal.* 20, 97-9(1915).—Discussion of a paper by Debrun (cf. *C. A.* 9, 1442).

P. calls attention to the necessity, for accurate work, of noting temps. at which solns. are prepd. and at which subsequent work is done and of making corrections for the temp. differences. It is pointed out that the coeff. of expansion of ordinary acid and alkali volumetric solns. and of 10, 12, and 15% sucrose solns. between 4° and 35° is nearly the same as that of H₂O. P. gives a portion of a table used by him and his colleagues for the past 20 yrs. in sugar work, showing excellent concordance with that of D., which is considered as the more exact.

F. W. SMITHER.

Precipitation of zinc and manganese with ammonium sulfide. F. SEELIGMANN. *Z. anal. Chem.* 54, 104 (1915).—To ppt. Mn with (NH₄)₂S in the presence of NH₄ salts, add a few drops of H₂O₂ to the soln. before adding the excess of NH₄OH and proceed as outlined in the former paper (cf. C. A. 9, 40). The detn. of Zn is not affected by NH₄ salts.

H. L. OLIN.

The estimation of niobium (columbium) in presence of tantalum, and some reactions of tantalum compounds. ARTHUR G. LEVY. *Analyst* 40, 204-18 (1915).—The volumetric method described for the estn. of Nb in the presence of Ta is based on the fluoride method of Osborne (*Am. J. Sci.* [3] 30, 328 (1885)), but reduction only goes as far as an oxide, Nb₁₀O₁₇, with a 0.1 N KMnO₄ equiv. of 0.00834 g. per cc. A series of detns. were made using known wts. of Nb₂O₅ or mixts. of Nb₂O₅ and Ta₂O₅, the conditions of operation being varied. The most satisfactory results were obtained by the following method: Dissolve the sample in 3-5 cc. HF in a 25 cc. Pt crucible and evap. nearly to dryness on a water bath or hot plate. Then transfer the material to a 500 cc. conical flask provided with a 2-holed rubber stopper carrying an inlet tube for H and an ordinary thistle funnel terminating at such a height that it was above the liquid at the end of the titration, i. e., above the 400 cc. level. The transfer is accomplished by the use of 40 cc. concd. HCl and 20 cc. water. Then add 10 g. Zn, and when the reaction slackens, generally in about 10 min., gently warm the flask on a hot plate. As soon as all the Zn is dissolved (in about 30 min.) dil. the contents of the flask with a cold, air-free soln. of 270 cc. water, 10 cc. concd. H₂SO₄, and 20 cc. of a cold satd. soln. of Na phosphate. Run in 0.1 N KMnO₄ at such a rate that single drops can just be distinguished, until the soln. became almost colorless. From this point on add the KMnO₄, cautiously, washing the successive drops down the funnel until the pink color persists 2 min. Both reduction and titration are made in an atm. of H. For further details of operation the original paper must be consulted. L. has previously shown that oxides of Nb and Ta both separately and when mixed are readily sol. in HF (48%), even after strong ignition. He has further detd. that large losses of Ta are caused by (a) dissolving Ta oxide in HF and igniting the residue obtained on evapn. to dryness; (b) igniting TaK₂F₇ with excess of KF at red heat; and (c) igniting mixts. of Ta oxide and NH₄F.

P. B. DUNBAR.

A method of assaying copper. A. FRASER. *J. Soc. Chem. Ind.* 34, 462-4 (1915).—The following reagents are required: (A) Standard Na₂S₂O₃ soln. (1 cc. = 10 mg. Cu); (B) soln. of I in KI (10 cc. = 1 cc. Na₂S₂O₃ soln.); (C) starch soln., acidified with AcOH just before using; (D) soln. of AcONa (1-5) made just acid with AcOH; (E) soln. of NaF made by shaking 45 g. of the salt with 1 l. H₂O, allowing to settle and drawing off the clear soln. Weigh 0.5-1.0 g. of sample into a porcelain dish (diam. = about 14 cm.) and treat with 5 cc. HCl and 15-20 cc. of a mixt. of HNO₃ and H₂SO₄ (12-1). Allow to stand overnight and then evap. to dryness. Heat until nearly all the H₂SO₄ is driven off, cool, add 5-6 drops of dil. H₂SO₄ (1-1) and 20-30 cc. H₂O and warm until all CuSO₄ is in soln. Allow to cool and add 10-20 cc. AcONa soln. followed by 20-50 cc. of NaF soln. The NaF soln. is added until the red color of the acetate of Fe disappears and then 10-15 cc. more are added. Add 3-5 g. of KI crystals and titrate the liberated I with Na₂S₂O₃ soln., using starch indicator. The Na₂S₂O₃ soln. is run in

while the contents of the dish are being mixed, and after a slight excess has been added the excess is titrated back with I soln. With ores containing only 1-2% Cu the reaction with KI is very slow and the blue starch-iodide color keeps on returning. $\text{Na}_2\text{S}_2\text{O}_3$ soln. must be added, however, till the liquid remains permanently decolorized. With sulfide ores containing much Sb or As, a variation in the method is necessary. With such ores, after treatment with the mixed acids, evapg., drying and driving off residual S, treat the residue a second time with the mixed acids, evap. and dry again. Then, after dissolving in H_2O and before adding the acetate, add a soln. of KMnO_4 , drop by drop, till a last drop permanently changes the green color of the liquid to a gray-violet. If the oxidation with HNO_3 has been complete, 1 drop of KMnO_4 is sufficient (1 cc. $\text{KMnO}_4 = 0.5$ cc. $\text{Na}_2\text{S}_2\text{O}_3$). Next, proceed as above, deducting 0.02 cc. from the reading on the $\text{Na}_2\text{S}_2\text{O}_3$ buret, or just destroy the violet color with FeSO_4 soln. and make no deduction. A more rapid modification of the method is as follows: Treat sample with the 3 acids, boil down over a flame, cool, dissolve in H_2O , pour into a dish, using the acetate and fluoride solns. to rinse the flask and titrate as usual. A rapid method for detg. Cu and Fe in the same sample is given. E. W. BOUGHTON.

The determination of zinc as zinc ammonium phosphate and its application in separations. P. ARTMANN. *Z. anal. Chem.* 54, 89-102(1915).—The solubility of ZnNH_4PO_4 in pure H_2O at 10.5° is 0.0145 g. per l., equiv. to 0.0053 g. Zn. To det. Zn by the application of the iodometric method for NH_3 (cf. C. A. 1, 537), dissolve the ppt. of ZnNH_4PO_4 (corrected for known vol. of wash H_2O) in hot dil. H_2SO_4 , cool, add NaOH in excess until the ppt. is redissolved, add 0.5 N NaOBr in excess and det. the excess iodometrically. To sep. and det. Zn in Zn-Cu solns. add ammon. tartrate and $(\text{NH}_4)_2\text{PO}_4$ and ppt. ZnNH_4PO_4 . Wash the ppt. with 1% $(\text{NH}_4)_2\text{PO}_4$ soln. until free from Cu and dissolve in dil. HCl. Add 10 cc. ammon. tartrate and 100 cc. H_2O , heat to boiling, add 10-15 cc. NH_4OH , and 10 cc. $(\text{NH}_4)_2\text{PO}_4$ soln. Add dil. HCl until faintly ammoniacal, boil off remaining NH_3 and allow ppt. to settle warm.

H. L. OLIN.

The separation of magnesium from lithium by means of ammonium carbonate in alcoholic solution. J. G. DINWIDDIE. *Am. J. Sci.* 39, 662-4(1915).—The EtOH soln. of $(\text{NH}_4)_2\text{CO}_3$ was made by mixing 1500 cc. of the satd. aq. soln. of $(\text{NH}_4)_2\text{CO}_3$ with 360 cc. of concd. NH_4OH and 1900 cc. of 93% EtOH, settling out the pptd. $(\text{NH}_4)_2\text{CO}_3$, and filtering the clear soln. The solns. used for analysis contained 0.2-0.3 g. of MgO and 0.08-0.35 g. of Li. To 15-20 cc. of the soln. containing Mg and Li, 25 cc. of 93% EtOH was added and 50 cc. of the pptg. mixt. The mixt. was stirred vigorously for 1 min. and set aside for 5 hrs. or more. The supernatant liquid was decanted upon a Gooch crucible, the ppt. was stirred with more of the pptg. mixt. and allowed to settle, and the liquid again decanted upon the Gooch crucible and washed with the pptg. mixt. In some cases the ppt. was dissolved in HCl and repptd., washed, ignited and weighed. By one pptn. 0.2 g. MgO was satisfactorily sepd. from 0.08 g. of Li, but with larger amts. of Li the pptd. NH_4MgPO_4 was contaminated with Li. Two pptns., however, yielded a very fair sepn. 0.2730 g. of MgO was found in a mixt. containing 0.2718 g. MgO and 0.347 g. Li as LiCl .

E. W. BOUGHTON.

Rapid analysis of bearing metals and high copper content alloys. C. G. LUTTS. *Met. Chem. Eng.* 13, 346-7(1915).—The method of Demorest (cf. C. A. 8, 36) is inadequate for some alloys containing much Cu. L.'s modification is as follows: Treat 1 g. of drillings with 50 cc. HNO_3 (d. 1.2) and after dissolving in the cold for a few min. place beaker on the hot plate and evap. to 10 cc. Dil. with H_2O and boil for about 1 min. Decant and filter, washing by decantation once with HNO_3 , and finally wash with hot H_2O . To filter paper and ppt. in a beaker add 40 cc. conc. H_2SO_4 and 15 cc. H_2O . Warm and add KClO_3 repeatedly until all C is oxidized. To the clear soln. add 0.5 g.

S and boil for 30 min. Cool, remove ball of S and dil. soln. with 3 times its vol. of H_2O . Any Pb that was carried down with Sb and Sn by treatment with HNO_3 will occur as $PbSO_4$ at this point and should be filtered off and weighed. Heat filtrate to 60° and add standard $KMnO_4$ soln. till a deep pink color is obtained. Stir and titrate back with standard $FeSO_4$ soln. The Fe factor of the $KMnO_4 \times 1.076$ gives the factor for Sb but this should be checked by standardizing the soln. against pure Sb. *Tin*: After titrating pour soln. into a large flask, add $\frac{1}{2}$ its vol. of conc. HCl (d. 1.20) and place on hot plate. If the alloy does not contain 15% or more of Sb add enough soln. of $Sb_2(SO_4)_3$ to bring total Sb to that amt. Heat to boiling and add Fe wire at intervals so as to evolve a rapid stream of H. The flask should have a loosely fitting stopper. After 45 min., cool and filter through asbestos. Titrate immediately with 0.1 N I soln., using starch indicator. One cc. 0.1 N I soln. = 0.00595 g. Sn, and is standardized against pure Sn dissolved in H_2SO_4 and reduced as above. *Lead*: Evap. soln. of Pb, Cu, etc., obtained above with conc. H_2SO_4 and det. Pb as $PbSO_4$. *Copper*: Pass H_2S through filtrate from $PbSO_4$. If alloy is high in Cu (about 75%) dissolve CuS in HNO_3 and evap. with H_2SO_4 . Dil., add NH_4OH till soln. is neutral, add 4 cc. HNO_3 (d. 1.42) and electrolyze at 3 v. and 0.3–0.5 amp., using rotating anode if possible. If Cu content is low a separate analysis is necessary. Dissolve 1 g. alloy in 40 cc. conc. H_2SO_4 , boil 1 min. and cool. Dil. with 2 vols. of H_2O , let settle and filter off $PbSO_4$, which can be weighed if a check detn. on Pb is desired. Heat filtrate to 60° and titrate for Sb with $KMnO_4$ and $FeSO_4$ as above. To soln. add 3 g. tartaric acid, make slightly alk. with NH_4OH and add 3 cc. conc. H_2SO_4 . Heat to boiling, add 2 g. $Na_2S_2O_3$ and then 1 g. $KCNS$ dissolved in H_2O . Warm for 15 min., filter on a Gooch crucible and wash with hot H_2O . Dry at 110° and multiply wt. of $CuCNS$ by 0.5226 to calc. % of Cu. *Iron*: If present, det. at this point by pptn. with NH_4OH with subsequent titration or weighing. *Zinc*: If present, boil off H_2S from filtrate from CuS , make soln. slightly acid, add 3–5 g. of $AcONa$ and an excess of $NaNH_2HPO_4$ soln. Let settle, filter, ignite and weigh Zn as pyrophosphate. Demiorest's method for metals containing only Sn, Sb and Pb is given.

E. W. BOUGHTON.

The determination of ammonia by the boric acid method. FERDINAND PILZ. *Z. landw. Versw.* 18, 55–7 (1915).—In the method of Winkler (cf. *C. A.* 9, 899), the condenser must be kept cool. The expense is greater than in the usual method and there are no compensating advantages.

L. J. GILLESPIE.

Detection of sodium hydrogen carbonate in sodium carbonate. HASLAM. *Boll. chim. farm.* 53, 271–2 (1914).—Small amts. of $NaHCO_3$ in Na_2CO_3 may readily be detected as follows: Dissolve a portion in boiled, distd. H_2O , add an excess of $CaCl_2$, filter after 4–5 min. and add several drops of NH_4OH to the filtrate. A ppt. of $CaCO_3$ is produced if an appreciable amt. of $NaHCO_3$ was present. If the amt. of $NaHCO_3$ present was very small, the ppt. does not appear for some 10 min. It is possible by this test to detect 1 part $NaHCO_3$ in 1000.

H. S. PAINE.

The volumetric determination of polythionic acids by potassium iodate. G. S. JAMIESON. *Am. J. Sci.* 39, 639–42 (1915).— H_2SO_3 can be detd. by titrating with a soln. of KIO_3 in the presence of 15–20% actual HCl and a small vol. of an immiscible solvent such as $CHCl_3$, according to the general method of Andrews (cf. *C. A.* 8, 3279). Expts. showed that $H_2S_2O_3$ and $H_2S_4O_6$ can be detd. in the same manner, while $H_2S_5O_6$, on account of its stability cannot be detd. by this method. $H_2S_5O_6$ reacts so slowly with KIO_3 in the presence of HCl that it is possible to titrate and det. the amt. of $H_2S_5O_6$ in the presence of large amts. of $H_2S_2O_3$.

E. W. BOUGHTON.

A method of estimating small amounts of carbon dioxide in the presence of sulfides. H. W. JONES. *The Rubber Industry* 1914, 191–2.—The CO_2 evolved by treating the sepd. mineral matter with HCl is absorbed in a soln. made by mixing 30 g. $BaCl_2$ in

180 cc. H_2O with 36 cc. NH_4OH and water sufficient to make 300 cc. The CO_2 is detd. by dissolving the filtered and washed BaCO_3 in HCl and detg. the Ba as sulfate.

W. F. ZIMMERLI.

The detection of phenol-formaldehyde condensation products. F. STEINITZER. *Kunststoffe* 5, 109-11 (1915).—A review of the tests given in the literature. F. W. S.

Estimation of methyl alcohol in presence of ethyl alcohol. G. C. JONES. *Analyst* 40, 218-22 (1915).—J. has studied the modification of Denigès' method by Simmonds (C. A. 6, 970) and emphasizes the importance of adhering rigidly to the definite conditions laid down. He recommends the use of a Schiff's reagent made by dissolving 0.2 g. of magenta base in 10 cc. freshly prepd., cold, satd., aq. soln. of SO_2 , and after 24 hrs. dilg. with 200 cc. water. The final color intensity may be increased by adding 5 cc. instead of 2.5 cc. of KMnO_4 soln. In this case the use of 1.0 cc. $\text{H}_2\text{C}_2\text{O}_4$ soln. is required.

P. B. DUNBAR.

The detection of methyl alcohol by the Denigès' reaction, and its determination in aqueous solution. T. VON FELLEBERG. *Mitt. Lebensm. Hyg.* 6, 1-24 (1915); cf. C. A. 4, 1443, 1725.—F. discusses the reaction in detail and outlines the following method for the estn. of MeOH in solns.: From a dil. soln. distil off 60%. If volatile acids or bases are present, add NaOH or H_2SO_4 ; in the presence of aldehydes, terpenes, or other unsatd. compds. add NaOH and AgNO_3 . To det. MeOH combined with pectin, distil off volatile compds., sapon. with NaOH and distil the MeOH from acid soln. The following solns. are necessary: (1) $\text{C}_2\text{H}_5\text{HSO}_4$: 21 cc. 95% EtOH in H_2O and 40 cc. H_2SO_4 (d. 1.84), made up to 200 cc.; (2) KMnO_4 soln.: 50 g. per l.; (3) $\text{H}_2\text{C}_2\text{O}_4$: satd. soln.; (4) H_2SO_4 (d. 1.84); (5) fuchsin bisulfite: 5 g. fuchsin, 12 g. Na_2S , and 100 cc. N H_2SO_4 per l.; (6) MeOH: 1% soln., 12.67 cc. (10 g.) per l. To 3 cc. of the distillate add 1 cc. soln. (1) and 1 cc. soln. (2) and shake for 2 min. Treat in the same way 2 standard MeOH solns., 0.5 cc. 1% MeOH and 2.5 cc. H_2O , and 1 cc. 1% MeOH and 2 cc. H_2O . To each of the three add 1 cc. soln. (3), then 1 cc. soln. (4) and finally 5 cc. soln. (5) and mix. Let stand 1 hr. and est. colorimetrically, using the known solns. as standards.

H. L. OLIN.

Reactions of vanillin. E. P. HAUSSLER. *Z. anal. Chem.* 54, 104 (1915); cf. C. A. 8, 2662; 9, 921.—Merck's pepsin gave with the biuret test a weak but distinct violet color. With vanillin and dil. EtOH it formed yellow rings which, on the addition of 10% HCl , turned violet-brown and finally reddish brown. Without the addition of vanillin, the pepsin gave a brown color only. Whether the positive factor in the vanillin HCl reaction was the pepsin itself or an enzyme occurring in a protein mixed with it, was not detd.

EDGAR T. WHERRY.

A lecture experiment to illustrate multiple crystallization. A. BEUTELL. *Breslau. Centr. Min. Geol.* 1915, 144-8.—Glass tubes 3 cm. in diam. are partially filled with S, exhausted and sealed. If tubes thus prepared are dipped in warm water for a few moments, and then cooled, a S coating will appear upon the walls; this resublimates

after a few moments. If the S end of the tube is immersed in water and warmed to 100° a white cryst. sublimate will appear on the cold portion of the tube. After a few months this sublimate becomes still more coarsely cryst. A. WANDTKE.

Covellite: A singular case of chromatic reflection. H. E. MERWIN. *Geophys. Lab. J. Wash. Acad.* 5, 341-4 (1915).—Covellite, cryst. CuS , is dark blue in powder, lighter blue on crystal surfaces, though varying in color with direction; cleavage plates appear in alcohol ($n = 1.36$) brilliant purple, in benzene ($n = 1.50$) reddish purple, and in methylene iodide ($n = 1.74$) red. Minute artificial crystals were found to transmit greenish light, owing to greater transmission in the center of the spectrum than at the ends, and measurements of n for diff. wave lengths showed remarkable variations, from 1.00 for 635 to 1.97 for 505 μ . The color effects noted are due to these variations in n combined with variations in reflective power for different wave lengths. E. T. W.

The occurrence of covellite at Butte, Mont. A. PERRY THOMPSON. *Bull. Am. Inst. Mining Eng.* 1915, 645-77.—Description of the mineral with discussion of its origin. H. L. OLIN.

Tetranickel triarsenide (maucherite) and its capacity as a silver precipitant. CHASE PALMER. *Z. Kryst. Min.* 54, 433-41 (1915); see C. A. 9, 44. E. T. W.

Bornite as silver precipitant. CHASE PALMER. U. S. Geol. Survey. *J. Wash. Acad.* 5, 351-4 (1915).—P. and Bastin (C. A. 7, 1857) have shown that chalcocite, Cu_2S , reacts with Ag_2SO_4 soln., and the reaction has been found to take place as follows: $\text{Cu}_2\text{S} + 2\text{Ag}_2\text{SO}_4 = 2\text{CuSO}_4 + 2\text{Ag} + \text{Ag}_2\text{S}$. It has also long been known that covellite, CuS , reacts with AgNO_3 to form $\text{Cu}(\text{NO}_3)_2$ and Ag_2S with no liberation of Ag. Therefore, 1 g. CuS will ppt. 2.26 g. Ag_2S , while 1 g. Cu_2S will ppt. 2.7 g. Ag, half free and half as Ag_2S . The mineral bornite contains Cu and Fe as sulfides, but the valences of the metals have never been definitely detd. A sample of bornite from Virgilina, Va., was purified by crushing and picking out visible chalcopyrite and other impurities, and was found to have the comp. Cu 62.50, Fe 11.64, S 25.4, sum 99.54%, corresponding to Cu_5FeS_8 with a slight excess of Fe, probably owing to undetected chalcopyrite. This was treated with Ag_2SO_4 soln. for 12 hrs., at first on the steam bath and then at room temp., and the products analyzed. For every atom of Cu dissolved one atom of free Ag and one Ag combined in sulfide form were pptd., proving that the Cu in bornite is in the cuprous form, so that the true formula of the mineral is $5\text{Cu}_2\text{S} \cdot \text{Fe}_2\text{S}_3$ or $\text{Cu}_{10}\text{Fe}_2\text{S}_{13}$. In writing the equation it is assumed that the Ag_2S combines with the Fe_2S_3 liberated, since the latter is not known as an independent mineral. The equation is: $\text{Cu}_{10}\text{Fe}_2\text{S}_{13} + 10\text{Ag}_2\text{SO}_4 = 10\text{Ag} + \text{Ag}_{10}\text{Fe}_2\text{S}_8 + 10\text{CuSO}_4$. E. T. W.

Datolite from Great Notch, New Jersey. C. W. COOK AND E. H. KRAUS. *Am. J. Sci.* 39, 642-5 (1915).—Chiefly crystallographic. The crystal faces are generally coated with stilbite, which is in such relationship with the datolite as to leave no doubt that the stilbite is younger. L. W. RIGGS.

The identity of footsite with connellite, with a description of two new occurrences of the mineral. W. E. FORD AND W. M. BRADLEY. New Haven. *Am. J. Sci.* 39, 670-6 (1915).—Specimens of "footeite" from the Bisbee District, Arizona, and "connellite" from the Tintic District, Utah, when compared with the original footeite and the original connellite were found to be the same species. The name connellite having priority over footeite, the latter must be discarded. Analyses: I, The original footeite, by Koenig; II, Connellite from Cornwall, by Penfield; III, Connellite from the Czar mine, Bisbee, Arizona, by Bradley; IV, Connellite from the Grand Central mine, Tintic District, Utah, by Bradley; V, Theoretical comp. according to the proposed new formula: $16\text{CuO} \cdot 2\text{CuCl}_2 \cdot 1\text{Cu}(\text{SO}_4(\text{NO}_3)_2) \cdot 19\text{H}_2\text{O}$.

L. W. RIGGS.

Interchange of bases in stilbite. A. BEUTELL AND K. BLASCHKE. Breslau. *Centr. Min. Geol.* 1915, 142-4.—Finely powdered stilbite was shaken with solns. of neutral and ammoniacal NH₄Cl. The Ca is entirely replaced by NH₄, the process going on more rapidly in the ammoniacal soln. The amt. of NH₄⁺ entering into combination corresponds to the amt. of Ca and consequently no union of NH₃ with the OH group takes place. Fresh stilbite exchanged all of its Ca in 15 days, while thoroughly dehydrated material had only 0.1 of its Ca replaced in the same time.

A. WANDTKE.

Apatite from the magnesite quarry at Sunk, Styria. O. GROSSPIETSCH. Prague. *Z. Kryst. Min.* 54, 461-6(1915).—The mineral occurs in well developed crystals in hydrothermal veins. Analysis indicated a formula corresponding to the theory of Rogers: 4[3CaO(PO₄)₂.CaF₂] + 3CaO(PO₄).CaO. The sp. gr. = 3.2057, and *c* = 0.73341. The *ns.* and double refraction were measured, but no relation between optical properties and F content could be demonstrated.

A. WANDTKE.

"Genno-ishi." T. HIKI. *Mem. Coll. Eng. Kyoto Imp. Univ.* [2] 1, 55-8(1915).—Genno-ishi (hammer-stone), from Shinano province, is compared with jarrowite from the Clyde Estuary, Scotland. The mineral is analogous to pseudogaylussite (calcite after gaylussite) and is found as isolated crystals in clayey shale. These crystals are acute pyramidal or prismatic with rough surfaces and are covered with small crystals arranged in parallel position. Analysis shows SiO₂, 0.64; Fe₂O₃, 3.44; Al₂O₃, 1.00; CaO, 52.33; MgO, 0.48; CO₂, 37.00%; P₂O₅ and org. matter not detd. The specimen from Clyde contained more MgO (4.94), P₂O₅ (2.23), and org. matter (5.94%), but the difference is probably due to less complete leaching out of MgCO₃ and P₂O₅.

R. L. SIBLEY.

Geology of Juneau district. FREDERICK B. HYDER. *Eng. Mining J.* 99, 901-2 (1915).—A summary of the knowledge of the Au deposits of the region. The ores occur chiefly in metamorphosed sedimentaries more or less closely associated with igneous rocks, especially with metagabbro and albite-rock dikes.

E. T. W.

Occurrence of platinum at Boss Mine, Nevada. J. C. KENNEDY. *Mining Eng. World* 42, 939-40(1915).—Little definite information as to the occurrence and origin of the ore is obtainable, and its nature is described only as a "mineralogical curiosity—rather soft and earthy in character." Some samples are said to yield as high as 1500 oz. Pt per ton, and other metals of the Pt group are present, along with Au, Ag, Cu, Pb, Zn, Hg, V, U, Ce, and Yt. Methods of assay are described, and it is stated that the Pt can be parted from the Au by HNO₃ alone, because of the large % of Pd present. Some recommendations as to methods of extn. of the Pt metals are also given. Cf. Knopf, C. A. 9, 1591.

E. T. W.

The Grong copper and pyrite mines of Norway. ANDREAS D. UDHANY. *Eng. Mining J.* 99, 889-92(1915).—In this region in the extreme northern end of Norway

3 groups of deposits are known. The Gjersvik deposits comprize large bodies of pyrite containing 2-2.2% Cu and 43% S, together with several lodes of chalcopyrite. The Joma deposits are chiefly pyrite averaging 44% S, with also some ore running as high as 2% Cu. The Skorovas deposits are pyrite nearly free from Cu but averaging up to 50% S. E. T. W.

Iron ore occurrences in Cape Breton. E. LINDEMAN. *Summary Rept. Mines Branch, Canada Dept. Mines* 1913, 31-6.—Numerous deposits of hematite occupying fissures and cavities in the Cambrian and the lower Carboniferous occur throughout Cape Breton. The Fe content varies from 48 to 62%. H. L. OLIN.

White mica occurrences in the Tete Jaune Cache and Big Bend districts of B. C. H. S. DE SCHMID. *Summary Rept. Mines Branch, Canada Dept. Mines* 1913, 42-9.—The principal Tete Jaune claims are located on Mica mountain at an elevation of 7000 ft. The muscovite crystals occur in pegmatite dikes with white microcline feldspar and quartz. The mica is free from stains and is of fair quality, but systematic mining would probably not be profitable on account of the remoteness of the field and the shortness of the working season. H. L. OLIN.

Moose Mountain District in Southern Alberta. D. D. CAIRNES. *Canada Dept. Mines Geol. Surv. Mem.* 61, 62 pp. (1915).—A detailed study of the coal and gas horizons in this district to indicate their positions in the geological column. The coal occurs as anthracite, semi-anthracite or bituminous, according to the amt. of local pressure caused by folding and twisting of the rocks. Some of the coals are lignites, while in one locality a seam was found which had altered to an impure graphite. The water, volatile combined matter, fixed C and ash of the coals were detd. by fast coking. R. L. SIBLEY.

Certain points in petrographic classification. WHITMAN CROSS. *Am. J. Sci.* 39, 657-61 (1915).—A reply to the criticisms of Daly and of Lindgren of the quant. classification of igneous rocks proposed by Cross, Iddings, Pirsson and Washington.

L. W. RIGGS.

The calculation of calcium orthosilicate in the norm of igneous rocks. HENRY S. WASHINGTON. *Geophys. Lab. J. Wash. Acad.* 5, 345-50 (1915).—In the original Quantitative System it was recommended that excess CaO be calcd. as $4\text{CaO} \cdot 3\text{SiO}_2$. As subsequent work showed the nonexistence of the latter compd., it was later suggested that $3\text{CaO} \cdot 2\text{SiO}_2$ be used. Still later work having demonstrated the comparative instability of this compd., it is now recommended that the normative compd. for CaO be taken as the orthosilicate, $2\text{CaO} \cdot \text{SiO}_2$. The change necessitates new equations for the calcn. of the norm, but comparatively few rocks are of such chem. character that this calcn. is necessary, and even when it is, the change has but little effect on the classificatory position of the rocks. A simplified procedure in calcg. the norm, which has been found most economical in time and labor, is described in detail, and a table for calcg. the amts. of $2\text{CaO} \cdot \text{SiO}_2$ given. E. T. W.

Geological-mineralogical observations in India. IV. Is there a possibility of simultaneous lateritic and non-lateritic weathering in the tropics? RICHARD LANG. Tübingen. *Centr. Min. Geol.* 1915, 148-60; cf. *C. A.* 9, 191, 584.—The laterite of India is only found under the brown and humous soil, and all evidence points to the fact that laterite is a fossil deposit, and belongs to a past period of dry climate; that during the wet climate since that time, only brown and humous soils have been formed. L. thus differs from Stremme and Glinka, who regard the laterite as a product of the moist conditions. A. WANDTKE.

Limestone solution on the bottom of Lake Ontario. E. M. KINDLE. *Am. J. Sci.* 39, 651-6 (1915).—The samples studied were brought to the surface in fishermen's nets about 20 miles S. W. of Brighton, Ont., from a depth of 150 ft. They had deeply

pitted surfaces, showing a much greater solvent action of the water than that which prevails at and near the surface. This difference K. attributes to the greater conc. of CO_2 at the depths mentioned, this CO_2 being furnished by the flora and fauna of the lake bottom. L. W. RIGGS.

Saline springs of Manitoba. L. H. COLB. *Summary Rept. Mines Branch, Canada Dept. Mines* 1913, 50-3.—A preliminary report on salt wells and springs in the Westbourne and Winnipeg districts. No chem. analyses have yet been made.

Progress of the Martin process in production of cast steel. G. SIROVICH. *Ann. chim. applicata* 3, 255-68(1915).—A description of the process, and of different forms of furnaces. S. predicts that this process will supplant the converter in all lines of the industry. S. LEVY.

Precipitating action of carbon in cyanide solutions. W. R. FELDTMANN. *Mining Sci. Press* 110, 791-6(1915).—In working with quartz veins of W. Africa F. found that the graphitic schist which is present ppts. Au from auriferous solns. in a manner analogous to the action of charcoal under like conditions. The Au is pptd. on the charcoal or schist as a compd., possibly a carbonyl aurocyanide. This Au compd. is decomposed and the Au is dissolved to a considerable extent by alkaline sulfide solns. Further expts. are being carried on to make practical use, in the cyanide treatment of ores, of this solubility of Au in alkaline sulfide solns. An attempt will be made to evolve an economical post-treatment of sand residues. L. A. TOUZALIN.

Home-made apparatus for cyanide tests. H. F. LUNT. *Mining Sci. Press* 110, 911-2 (1915). E. J. C.

Fumeless ore furnace burning crude oil. ANON. *Mining Eng. World* 42, 991 (1915).—An editorial discussion of an exptl. hydro-vacuum furnace described by Marquand in a thesis submitted to the Univ. of Calif. F. W. SMITHER.

Wet methods of mercury extraction. E. B. THORNHILL. *Mining Sci. Press* 110, 873-4(1915).—As a result of expts. Mulholland suggested grinding the ore in an alk. sulfide soln., whereby the cinnabar was dissolved, sepg. the soln. from the ore by filtration or decantation, pptg. the Hg out of soln. with $\text{Zn}(\text{OH})_2$, which brought down a mixt. of ZnS and HgS, dissolving the ZnS out of the ppt. with H_2SO_4 , and retorting the

residual HgS with CaO or Fe to obtain Hg. The H_2S formed by dissolving the ZnS was used to regenerate the Na_2S soln. *Reactions:* $Na_2S + HgS = Na_2S.HgS$; $ZnSO_4 + 2NaOH = Zn(OH)_2 + Na_2SO_4$; $Zn(OH)_2 + 2NaOH = Na_2ZnO_2 + 2H_2O$; $Na_2S.HgS + Na_2ZnO_2 + 2H_2O = HgS + ZnS + 4NaOH$; $ZnS + H_2SO_4 = ZnSO_4 + H_2S$; $2NaOH + H_2S = Na_2S + 2H_2O$. Where the cost of mining is low, M. estd. that Hg ores as poor as 0.3% could be worked at a profit by this process; however, no com. application of it has been made. A wet method to recover Hg as HgS from amalgamation tailings is in use at the Buffalo Mines, at Cobalt. This should be equally applicable to cinnabar ores. The HgS is dissolved out of the tailings with Na_2S soln. and the Hg pptd. on scrap Al. *Reactions:* $Na_2S + HgS = Na_2S.HgS$; $3Na_2S.HgS + 8NaOH + 2Al = 3Hg + 6Na_2S + 2NaAlO_2 + 4H_2O$; $2NaAlO_2 + Ca(OH)_2 = 2NaOH + Ca(AlO_2)_2$. From the equation, 11 lbs. Hg should be pptd. with 1 lb. Al; practically the ratio is about 7:1, as some H is evolved during the pptn. Not only is the Na_2S combined with the HgS regenerated, but the S of the HgS goes to form Na_2S . The NaOH is regenerated by the addition of CaO, which also aids settling or filtration. With a clean cinnabar ore the Hg would be obtained wholly in the liquid state without retorting, and by straining through canvas it would be made ready for market. Over 40,000 lbs. of Hg have been recovered by the Buffalo Mines by this process at an approx. cost of 13 cents per lb. The cost of installation should not exceed \$500 per ton capacity. Since standard cyanide machinery can be used (crushers, pebble mills, Dorr classifiers, thickeners, etc.), the plant could be erected in a minimum of time and Hg could be placed on the market in 3 to 4 days after the plant was put into operation. The Hg produced at the Buffalo Mines contained only traces of Ag. Com. crystals of Na_2S cost \$1.25 per cwt. f.o.b. chemical works, and the Al for pptn. consists of casting-foundry turnings costing \$2.50 per cwt., f.o.b. foundry.

ISADOR MILLER.

The effect of boron upon the magnetic and other properties of electrolytic iron melted in vacuo. TRYGVE D. YENSEN. *Univ. Ill. Eng. Exp. Sta. Bull.* 77(1915); cf. *C. A.* 9, 906.—The addition of small quantities of B to Fe melted in *vacuo*, causes the simultaneous reduction of FeO and the formation of B-Fe alloys. The magnetic properties of the Fe are slightly improved, probably because of the reduction of the FeO, but reach a max. at 0.05% B_2O_3 or 0.4% B_2O_3 -flux, beyond which they drop rapidly. The specific elec. resistance is increased 0.62 microhms for each 0.1% B combined with the Fe. Like C, B raises the elastic limit and increases the ultimate strength but decreases the toughness of Fe.

Conclusions from steel rail research. COMMITTEE AM. RAILWAY ENG. ASSOC. *Iron Age* 95, 622-3(1915).—Rail failures may be divided into 4 classes: (1) crushed and split heads caused by segregation, (2) broken rails, square and angular, (3) broken bases, possibly caused from seams developed in first blooming passes and (4) transverse fissures, cause unknown.

H. V. MAIN.

Plating iron with lead or aluminium. W. *Metalltechn.* 39, 289; *Chem. Tech. Rept.* 38, 292 (1914).—The Fe to be coated must be scrupulously clean. In Pb plating the temp. of the bath should be 20–30° above the m. p. of Pb (327°). The bath should be protected from oxidation by means of a coating of borax, ZnCl_2 or NH_4Cl . Instead of Pb alone, the bath may consist of one of the following alloys: (1) Pb 8, Sn 1, Zn or Sb 0.02, BaCl_2 0.05–0.1 parts; (2) Pb 17, Sn 3 parts; (3) Pb 17, Sn 3, Sb 1 and Cu 1 part. Before being coated the Fe should be heated under powdered charcoal in a specially constructed oven, to avoid oxidation. For plating with Al the method of Franz Jordan is recommended, using EtOH as a reducing agent. SIMON MENDELSSOHN.

Nature of the protective oxidized coating of sheet iron for roofing. MATVEEV. *Rev. métal.* 11, 480–2 (1914); *J. Soc. Chem. Ind.* 33, 595.—The protective coating of roofing (Russian) Fe, although consisting mainly of Fe_2O_3 , also contains FeO present in a compact state in contact with the metal and forming a kind of skeleton in which the protective but porous and friable magnetic oxide is held. E. J. C.

Electric arc welding. J. F. LINCOLN. *Iron Age* 95, 949 (1915); cf. *C. A.* 9, 1455.—Welding is done with a C or Fe electrode; the latter does not tend to warp the work, but is not so rapid. The elec. welding machine is made like a transformer to save current loss. The better type gives voltage according to load instead of const. voltage.

Ger., 281,311, Jan. 7, 1910. W. MATHESIUS. Obtaining metallic iron by the reduction of the Fe_2O_3 , contained in the ores, by means of CO or gases containing C, at a temp. maintained const. below the sintering temp., supplying heat by previous heating of the gas and ore to such an extent that the reaction proceeds without further exterior heating. In a vertical furnace the ore to be reduced moves downward, while the reducing gases flow upward. Both ore and gas must be raised to the reaction temp. (700 – 900°) before entering the furnace. Ordinarily a period of several hrs. of contact between the ore and the gas is sufficient to yield metallic Fe, suitably carbonized. The preheating of the ore is effected in the usual rotary furnaces which are heated by flue gases of the reducing shaft. The flame is controlled as to its oxidizing action so that FeO and Fe_3O_4 may be oxidized to Fe_2O_3 . Generator or coke-oven gases, natural gas, petroleum gases, and the like, may serve as the reducing gases. These gases may be preheated to 700 – 900° in the known Cowper app. which is in turn heated by the flue gases of the reducing furnace. The ores issuing below from the reducing furnace are cooled by being led by and in contact with H_2O -cooled Fe furnaces, and finally sprayed with H_2O so that upon coming in contact with atm. air the temp. is not over about 150° , thereby avoiding reoxidation of the finely divided Fe. The Fe is then sepd. in the dry or wet way, or magnetically. The process is applicable also for the sepn. of Ni, Co, Cu, Sn, etc.

Ger., 281,386, Aug. 10, 1912. STAHLWERK BECKER, AKT.-GES. In mfg. high speed steel, Co is added to the steel of known compn., whereby its life, even when red hot, and when working at a high speed, can be increased materially. A good high speed steel contains, *e. g.*, besides Fe, 0.70% C, 5% Cr, 18% W, 1% V, and 0.75% Mo. To this steel, Co, 10%, is added. According to expts. carried on at the Imperial Technical High School, at Berlin, the life of such steel is increased, under like conditions, 4–5 times when operating at a speed of 25 m., 6 times at a speed of 20 m., and 10 times at a speed of 15 m. A Cr-Ni steel of 100 kg. test was employed in these experiments.

Action of concentrated sulfuric acid on acetylene compounds. YU. S. ZAL'KIND. *J. Russ. Phys. Chem. Soc.* 46, 897-900 (1914).—According to Dupont (*C. A.* 8, 2147), certain glycols and related compds. give a deep coloration with H_2SO_4 . To det. what kind of alcs. give this reaction, numerous substances were examd. The expts. were made by adding to 5-6 cc. of concd. H_2SO_4 a crystal of the substance or, better, a soln. of it in a few drops of AcOH or $CHCl_3$. The results were as follows: The γ -glycols of the C_2H_5 series, e. g., the Me, Et and Ph derivs. of $(HOCH_2C\equiv)_n$, give with H_2SO_4 intense colorations, sometimes with fluorescence. The colorations for the corresponding C_2H_4 compds. are much paler, and for the corresponding satd. glycols still paler. In both of these series the colorations for aryl derivs. are slightly deeper than for the aliphyl derivs. The gradual diminution in the intensity of coloration in passing from the C_2H_5 to the satd. series shows that this reaction is characteristic not of the position of the O, but of the presence of multiple, particularly triple, unions. This is further corroborated by the fact that both $Me_3C(OH)C\equiv CPh$ and $MeC(OH)(C\equiv CPh)_2$ are colored by H_2SO_4 , and that the coloration is deeper for the latter (with 2 such unions) than for the former. In all the cases examd. the color reaction is given only by concd. H_2SO_4 . If the amt. of material is small and the time it is left in contact with the acid short, the color disappears upon dilm. with H_2O . If the H_2SO_4 is dild. with AcOH the coloration persists in higher dilns. than when H_2O is the diluent. These facts show that we have here a reaction of halochromy and not a resinification or condensation.

H. M. GORDIN.

Action of magnesium on tribromoisopentane. Synthesis of a hydrocarbon $C_{10}H_{18}$ with open chain. VL. KRESTINSKII. *J. Russ. Phys. Chem. Soc.* 46, 900-8 (1914).—As shown in a previous article (*C. A.* 7, 3964), the interaction of Mg with $MeCBr(CH_2Br)_2$ yields $(CH_2\cdot CMeCH_2)_n$. In order to see whether other bromides with the Br in the 1,2,3-positions react in a similar manner, a mixt. of $MeCHBrCBrMeCH_2Br$ (a) and $Me_2CBrCHBrCH_2Br$ (b) was made to react with Mg. The mixt. of these bromides was obtained by Ipat'ev's method (*J. Russ. Phys. Chem. Soc.* 33, 532), but using Fe or Al wire as a catalyzer. The latter greatly facilitates the reaction, giving at once the tribromides, and not at first a mixt. of di- and tribromides as is obtained when the catalyzer is omitted. It was found that (a) gave the hydrocarbon $(MeCH\cdot CMeCH_2)_n$ (c), while (b) gave the isomeric hydrocarbon $(Me_2C\cdot CHCH_2)_n$ (d). (c) b. $153-5^\circ$, d_4^{20} 0.7767, n_D^{20} 1.44453, is oxidized by $KMnO_4$ to $[CH(OH)CO_2H]_n$ (e), AcOH and CO_2 , and is converted by HBr into a liquid bromide $(MeEtCBrCH_2)_n$. (d) b. $161-3^\circ$, and gives upon oxidation a mixt. of what seems to be AcOH and (e). These expts. prove that, in general, tribromides with the Br in the 1,2,3-positions are converted by Mg into diethylene hydrocarbons of a definite constitution, and that the linking of the residues takes place between those C atoms which have the Br in primary positions. The results of this reaction with C_4H_9Br , and the tribromide of tertiary hexyl alc. are promised for the near future.

H. M. GORDIN.

Isomerization of the higher acids $C_nH_{2n-2}O_2$ under the influence of caustic alkali. I. V. EGOROV. *J. Russ. Phys. Chem. Soc.* 46, 975-94 (1914).—Unsatd. acids having 1 double union in the β,γ -position are isomerized by fusion with alkali to acids with this union at the α,β -position. This explains why both kinds of acids yield at a higher temp. the same 2 satd. acids, resulting from a breakage of the mol. at the α,β -position.

Acids having the double union further from the CO_2H than the β, γ -position are generally supposed not to be affected by fusion with alkali. E.'s expts. with oleic and undecylic acids show that this supposition is wrong, since the former, with the double union in the 8,9-position, was isomerized by this method to the acid $\text{Me}(\text{CH}_2)_{11}\text{CH}:\text{CH}(\text{CH}_2)_2\text{CO}_2\text{H}$ (a) (m. $42-3^\circ$), and the latter to the isomeric acid $\text{MeCH}:\text{CH}(\text{CH}_2)_7\text{CO}_2\text{H}$ (b), b_{748} $274-6.5^\circ$, d_0^{20} 0.9309, d_4^{25} 0.9119; *barium, silver and copper salts; ethyl ester* (c), b. $257-9^\circ$, d_0^{20} 0.89665. By the action of NH_3 on (c) the amide $\text{C}_{10}\text{H}_{19}\text{CONH}_2$ was obtained, m. $77-8.5^\circ$. (b) was also converted into the corresponding alcohol, $\text{C}_{11}\text{H}_{21}\text{OH}$, b_{718} $240-6^\circ$, d_0^{20} 0.8628, d_4^{25} 0.86027; *urethan*, $\text{C}_{11}\text{H}_{21}\text{O}_2\text{N}$, m. 46.5° . (a) was accompanied by palmitic and a hydroxystearic acid. The latter is either $\text{Me}(\text{CH}_2)_{11}\text{CH}(\text{OH})(\text{CH}_2)_4\text{CO}_2\text{H}$, or $\text{Me}(\text{CH}_2)_{12}\text{CH}(\text{OH})(\text{CH}_2)_3\text{CO}_2\text{H}$, and its formation shows that OH acids are produced as intermediary products in the isomerization. When decompd. by E.'s method ("Action of Nitrogen Peroxide on Unsaturated Acids," Moscow, 1903), (a) gave tridecylic and glutaric acids, while (b) gave azelaic, acetic, suberic and what seemed to be propionic acids. The formation of the last 2 would seem to indicate that (b) was contaminated with another isomer, $\text{EtCH}:\text{CH}(\text{CH}_2)_6\text{CO}_2\text{H}$. This suggestion is supported by the fact that from the mother liquor of the above urethan another urethan sepd. out having a different cryst. form. H. M. G.

Action of phosphorus pentoxide and zinc chloride on the glycerides of hydroxystearic and ricinoleic acids and the polymerization that accompanies the reaction. Preliminary communication. S. FOKIN. *J. Russ. Phys. Chem. Soc.* 46, 1027-42 (1914).—In a previous article (*C. A.* 8, 2550) it was stated that the product of interaction of P_2O_5 or $(\text{CO}_2\text{H})_2$ on hydroxystearic acid (a) consisted chiefly of an oleic acid (b) having the double union between the 12th and the 13th C atoms (counting from the C of the CO_2H inclusive), while of the isomeric (b) with this union at the 11,12-position only a small amt. is produced. Further exam. showed this to be incorrect, the reaction of (a) with either P_2O_5 , $(\text{CO}_2\text{H})_2$ or ZnCl_2 going equally well towards the formation of both of the above isomers of (b). The product obtained by Khonovskii (*C. A.* 6, 737) by acting on ricinoleic acid (c) with HBr and then removing the latter by means of alc. KOH was, according to F., a mixt. of at least 6 isomeric linoleic acids (d), and not a mixt. of the 2 isomeric (d) obtained by F. by the action of P_2O_5 on castor oil. According to Gruen (*C. A.* 3, 1749), P_2O_5 merely changes (c) to a polymer $(\text{C}_{18}\text{H}_{34}\text{O}_2)_n$. F. thinks that G.'s caoutchouc-like substance is a polyprene (e) formed from that intermediately produced (d) which contains conjugated double unions, the reaction being similar to the formation of caoutchouc from certain hydrocarbons with conjugated unions, particularly those of the allene type. The (c) in changing to (e) is first converted into an inner anhydride, hence (e) cannot have 3 atoms of O per mol. From the glyceride or the Et ester of (a) no (e) is obtainable by means of ZnCl_2 , showing that the polymerization of (c) to (e) is not due to OH groups, but to conjugated double unions. (e) may also be obtained by the action of ZnCl_2 on wood oil, but then it differs in several respects from the (e) obtained from castor oil, making it probable that the (d) of wood oil contains allene double unions. H. M. GORDIN.

Molecular combinations of amines. A. KOCHUBBI. *J. Russ. Phys. Chem. Soc.* 46, 1048-55 (1914).—By the action of $\text{K}_2\text{Fe}(\text{CN})_6$ on $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ (a) a dark blue, almost black, compound, $4\text{C}_6\text{H}_4(\text{NH}_2)_2 \cdot \text{Fe}(\text{CN})_6 \cdot 2\text{H}_2\text{O}$, was obtained; insol. in H_2O and in most org. solvents, and but slightly sol. in hot mineral acids with formation of red solns. which are decolorized by SnCl_2 and colored yellow by Br in H_2O . With $\text{H}_2\text{Fe}(\text{CN})_6$ (a) gave a whitish substance. Leucoaniline gave with $\text{K}_2\text{Fe}(\text{CN})_6$ a dark blue compound, $[\text{CH}(\text{PhNH}_2)_2]_4 \cdot \text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$. These compds. are supposed to have a meriquinoid constitution. Moir's opinion that the oxidation products of diamines are salts of the base $\text{C}_{60}\text{H}_{48}\text{N}_{16}$ (*Chem. Zentr.* 1907, I, 344) is considered insufficiently sup-

ported by facts. Reviewing the numerous combinations of amines, the following conclusions are drawn: The amines are capable of uniting with both org. and inorg. substances; most of these combinations form salts and NO_2 derivs.; the salts obtained by partial oxidation of aryl diamines also are such mol. combinations. Werner's theory makes it possible to clear up the constitution of these combinations. An example of a rather complex formula which may be assigned to the above compds. is given.

H. M. GORDIN.

Methylantracene from frangula-emodin. N. KRASOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 1067-75(1914).—There being a difference of opinion as to the constitution of the methylantracene obtained from catharto-emodin and that from frangula-emodin, K. reexamd. both and several of their derivs. and compared them with the synthetic α - and β -methylantracenes and their corresponding derivs. The results showed that the compd. from both sources is identical with β -methylantracene.

H. M. GORDIN.

Döbner's benzpyrocatechol. NIK. ROZHDESTVENSKII. *J. Russ. Phys. Chem. Soc.* 46, 1075-7(1914).—Döbner (*Ann.* 210, 246) and Bartolotti (*Gazz. chim. ital.* 27, I, 286) give different values for the m. p. and the amt. of H_2O of hydration for $\text{BzC}_4\text{H}_5(\text{OH})_2$ (a). R. prepd. this compd. by the action of Bz_2O on $o\text{-C}_6\text{H}_4(\text{OH})_2$ in the presence of ZnCl_2 and found that, when dried over H_2SO_4 , it contained no H_2O at all, and that together with (a) there was formed BzOH . Dry (a) m. 134° . H. M. G.

Etherates of aluminium iodide. N. DOMANITZKII. *J. Russ. Phys. Chem. Soc.* 46, 1078-82(1914).—The interaction of Al with allyl iodide results in the formation of the aluminium iodide etherate, $\text{AlI}_3 \cdot \text{Et}_3\text{O}$ (a), diallyl and a small amt. of an Al org. compd. (a) forms colorless or yellowish crystals, m. about 49° , sol. in Et_2O and CS_2 , is decompd. by H_2O with a hissing noise and formation of the basic aluminium iodide etherate, $\text{Al}(\text{OH})_3 \cdot \text{AlI}_3 \cdot \text{Et}_3\text{O}$ (b), colorless crystals, may be kept unchanged under Et_3O at ordinary temp., insol. in Et_2O , but sol. in CS_2 with sepn. of $\text{Al}(\text{OH})_3$, deliquesces in the air, and is slowly and quietly decompd. by H_2O . The reaction of transformation of (a) into (b) by H_2O is: $2\text{AlI}_3 \cdot \text{Et}_3\text{O} + 3\text{H}_2\text{O} = \text{Al}(\text{OH})_3 \cdot \text{AlI}_3 \cdot \text{Et}_3\text{O} + \text{Et}_3\text{O} + 3\text{HI}$.

H. M. GORDIN.

New general method of formation of mercaptans. B. K. MERZHKOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 1082-4(1914).—All of the known methods for prepg. mercaptans are either clumsy or applicable to particular cases only. M.'s general method is based upon the following reactions ($\text{R} = \text{alkyl}$): $3\text{ROH} + 3\text{Br} + \text{P} = 3\text{RBr} + \text{P}(\text{OH})_3$; $4\text{P}(\text{OH})_3 + \text{Na}_2\text{SO}_4 = \text{Na}_2\text{S} + 4\text{H}_3\text{PO}_4$; $\text{Na}_2\text{S} + \text{H}_3\text{PO}_4 = \text{Na}_2\text{HPO}_4 + \text{H}_2\text{S}$; $\text{RBr} + \text{H}_2\text{S} = \text{RSH} + \text{HBr}$. The Br is added, with const. stirring and cooling, to the mixt. of the alc., P and not quite dry Na_2SO_4 , and the product, consisting of RSH, unchanged ROH and RBr, is distd. with steam. The RSH is sepd. from the ROH and the RBr by soln. in KOH and repptn. with HCl. The reaction was verified on PrOH , iso-BuOH and tert-AmOH .

H. M. GORDIN.

Homologs of tetramethyleneglycol. VIT. LONGINOV. *J. Russ. Phys. Chem. Soc.* 46, 1084-97(1914).—With a view to making homologs of $(\text{HOCH}_2\text{CH}_2)_n$, L. started with $\text{EtO}_2\text{CCH}_2\text{CH}(\text{CO}_2\text{Et})_2$ (a) made by Bischoff's method (*Ann.* 214, 58). Yield, 50%. What B. overlooked was that (a) is accompanied to the extent of 12% by the ester $(\text{EtO}_2\text{C})_2\text{C}(\text{CH}_2\text{CO}_2\text{Et})_2$, very thick oil, b_{11} $187-9^\circ$. By warming (a) with EtBr in presence of EtONa , the H of its CH is replaced by Et, and the resulting compd. upon reduction with Na in alc. (Bouveault and Blanc, *Compt. rend.* 136, 1676) gives β -ethyltetramethyleneglycol, $\text{HOCH}_2\text{CH}_2\text{CH}(\text{Et})\text{CH}_2\text{OH}$ (yield, 40%), thick, colorless and odorless liquid, does not solidify at -20° , sol. in H_2O , b_{10} $129-31^\circ$, d_{40}^{20} 0.9825, n_D^{20} 1.454. Similarly, by acting on (a) with PrBr and reducing the resulting compd.

with Na in alc., β -propyltetramethyleneglycol, $\text{HOCH}_2\text{CH}_2\text{CHPrCH}_2\text{OH}$ (b) is obtained, b_{10} 138–40°, d_4^{20} 0.9625, n_{20} 1.454, resembles the preceding compd. in appearance. By heating (b) with HBr in a sealed tube 2 compds. were obtained: 2-propyl-1,4-dibromobutane, $\text{CH}_2\text{BrCH}_2\text{CH}(\text{Pr})\text{CH}_2\text{Br}$ (c) (not pure), b , 103°, d_4^{20} 1.5269, n_{20} 1.5018, and β -propyltetrahydrofuran, $\text{PrCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2$, light, colorless, very mobile

liquid, b_{760} 144°, but easily volatile even at ordinary temp., d_4^{20} 0.8618, n_{20} 1.4243. By heating (c) in a sealed tube with NH_3 in MeOH it is converted into β -propylpyrrolidine, $\text{PrCH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2$, colorless, mobile liquid having the odor of piperidine,

fumes in the air, readily absorbs H_2O and CO_2 , b_{760} 158–60°, gives an oily chloroaurate. By Gabriel's method (Ber. 21, 2669) (c) was converted into β -propyltetramethylene-dinaphthalimide, $(\text{C}_8\text{H}_4\text{O}_2)_2\text{NCH}_2\text{CHPrCH}_2\text{CH}_2\text{N}(\text{C}_8\text{H}_4\text{O}_2)$ (m. 99–100°) which, when heated with fuming HCl to 180°, changed to β -propylputrescine hydrochloride, $\text{C}_7\text{H}_{15}\text{N}_2 \cdot 2\text{HCl}$, hygroscopic, odorless powder, m. 247–8°. The homologs of isoprene will be reported upon later.

H. M. GORDIN.

Isomeric transformations of cyclic α -monochloro ketones. AL. FAVORSKII AND V. BOZHOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 1097–102 (1914).—In analogy with open chain α -Cl ketones (*J. Russ. Phys. Chem. Soc.* 26, 559; 27, 8), cyclic α -Cl ketones ought to be converted by alkalis into acids containing 1 C atom less in the ring than the original ketone. Expts. proved this to be so, α -chlorocyclohexanone (a) giving cyclopentanecarboxylic acid, while chloro-*m*-methylcyclohexanone (b) gave methylcyclopentanecarboxylic acid (c). It is supposed that both oxidation and reduction take place in this reaction, the CO changing to $\text{C}(\text{OH})_2$, and that after formation of an oxide there is a loss of HCl with formation of the acid. Thus in the case of

used in this reaction was not established. If it be $\begin{array}{c} \text{MeCHCH}_2\text{CO} \\ | \quad | \\ \text{CH}_2\text{CH}_2\text{CHCl} \end{array}$, then (c) is

$\begin{array}{c} \text{MeCHCH}_2 \\ | \quad | \\ \text{CH}_2\text{CH}_2 \end{array} \text{CHCO}_2\text{H}$, while if in (b) the Me has another position, it will have the corresponding position in (c).

H. M. GORDIN.

Theory of nitration mixtures as applied to nitronaphthalenes. A. SAPOZHNIKOV. *J. Russ. Phys. Chem. Soc.* 46, 1102–10 (1914).—The results of Patart's expts. on the relation between the comp. of the nitration mixt. and the degree of nitration of C_{10}H_8 (*Mémoires des poudres et de salp.* 9, 11) were recalcd. in mol. % and represented diagrammatically in triangular coordinates. It is shown that, as in the nitration of cellulose, this form of diagram is to be preferred to the rectangular system used by P., and that S.'s theory of nitration (*C. A.* 3, 2223) holds good in this case too. The diagram indicates what comp. of the nitration mixt. is best suited for obtaining the desired nitrated compd. Thus, $\text{C}_{10}\text{H}_8(\text{NO}_2)_4$, requiring a mixt. of the highest nitration power, is produced when the HNO_3 , H_2SO_4 and H_2O are in such proportions that the whole of the HNO_3 is in the form of the monohydrate, which may be adjusted in various manners by adjusting the relative amts. of H_2SO_4 and H_2O taken for a given amt. of HNO_3 . The concn. of the HNO_3 in this case must, however, not drop below 35 mol.

%. The most suitable proportions of the ingredients for the production of $C_{10}H_8(NO_2)_2$ are those corresponding to $HNO_3 + H_2SO_4 + H_2O$. Between the concn. of 33 and 20 mol. % of HNO_3 is the region for the formation of $C_{10}H_8(NO_2)_2$, and below 15 mol. % of HNO_3 is the region for $C_{10}H_7NO_2$. While there is thus a general resemblance between the triangular diagrams of cellulose and $C_{10}H_8$, there is, however, an essential difference when the comp. of the nitration mixt. approaches pure H_2O or pure H_2SO_4 . Thus in the case of cellulose nitration becomes altogether impossible when the concn. of the H_2O exceeds 65 mol. %, or when the mixt. consists of HNO_3 and H_2O alone, mol. per mol., while $C_{10}H_8$ may be nitrated with a mixt. of HNO_3 and H_2O containing about 80 mol. % of the latter. Again with cellulose an undue concn. of H_2SO_4 makes nitration impossible on account of a reversal of the reaction, the concd. H_2SO_4 decomp. the esters produced, while with $C_{10}H_8$ very concd. H_2SO_4 simply chars the org. compd., frequently with formation of dark-colored products and evolution of N oxides. The latter diminish the yield by further oxidizing the NO_2 compds. These differences between the conditions of nitration of cellulose and $C_{10}H_8$ show that for the successful nitration of a given substance the required conditions must be maintained. The failure to adhere to proper conditions accounts for the unsatisfactory nitration expts. of many investigators.

H. M. GORDIN.

Tetranitromethane as reagent for the structure of molecules. O. FILIPOV. *J. Russ. Phys. Chem. Soc.* 46, 1199-201 (1914).—Expts. showed that, contrary to Ostrovnitskii's statement ("Caoutchouc and its Analogs," 1913, 42), $C(NO_2)_4$ gives no color reaction with cyclobutane derivs. Hence O.'s objection to Harries' 4-membered ring formula for caoutchouc because its bromide is not colored by this reagent is groundless. Equally groundless is his "corroboration" of Willstätter's formula for the hydrocarbon obtained by splitting off CO_2 from sorbic acid simply because it is colored by $C(NO_2)_4$.

H. M. GORDIN.

Mechanism of Strecker's reaction. G. L. STADNIKOV. *J. Russ. Phys. Chem. Soc.* 46, 1201-15 (1914).—Polemical. S. upholds his view of the mechanism of Strecker's reaction (*C. A.* 1, 1545) against Snyesarev (*C. A.* 8, 2550), claiming that the work of the latter is unreliable for several reasons, chief of which are the following: He failed to protect his reaction mixts. against the H_2O , HCl and NH_3 frequently present in the lab.; he boiled the mixts. too long, and he used KOH for the liberation of bases from their salts, thus producing NH_3 by the interaction of the alkali with the nitrogenous material and ascribing it to spontaneous decompn. The author also reproaches Krasuskii ("Reaction of NH_3 and Amines with Org. Oxides," *Diss. Kiev* 1913) for unjustly accusing him of having borrowed his ideas on this subject from K.

H. M. GORDIN.

New reaction for compounds containing the pyridine nucleus. A. E. CHICHEBABIN AND O. A. ZEIDE. *J. Russ. Phys. Chem. Soc.* 46, 1216-36 (1914).—When pyridine (a) or such of its derivs. as have the α -positions free are treated with $NaNH_2$ and the resulting compds. decompd. with H_2O , the H in these positions is replaced by NH_2 . Thus with 1 mol. of (a) $NaNH_2$ gave α - $C_5H_4NNH_2$ (b); (a) + $NaNH_2 = C_5H_4(NHNa)N + H_2$; $C_5H_4(NHNa)N + H_2O = (b) + NaOH$ (yield, about 70%). With diazobenzene salts in presence of $AcONa$ (b) gives a cryst. compound, $PhN:NNHC_5H_4N$, m. 176°. (b) also resembles $PhNH_2$ in being readily nitrated (see next abstr.). Similarly, α -picoline gave with $NaNH_2$, α' -amino- α -picoline, $C_8H_7NMeNH_2$ (c) (yield, 25%), extremely hygroscopic crystals, m. 36.5°. The β -H in (a) or its derivs. is not replaceable by NH_2 by this method, while with respect to the γ -position expts. have so far been inconclusive. Instead of $NaNH_2$, $RNHNa$ (R = org. radical) may be used, though the yield of phenylaminopyridine, C_5H_4NNHPh , obtained from $PhNHNa$ and (a) seems to be very small. It is possible that the substitution of $RNHK$ for $RNHNa$ will improve the yield. When both α -positions in (a) are free it is possible

by means of this reaction to replace both H in these positions by NH_2 . Thus, with double the amt. of NaNH_2 as is used in prepg. (b), (a) gave $\alpha, \alpha' \text{-C}_6\text{H}_2\text{N}(\text{NH}_2)_2$ (d) (Meyer and Tropsch, C. A. 8, 1575). Yield, 50%. An important peculiarity of (d) is its ability to copulate with diazo compds. with formation of azo dyes, resembling in this respect $m\text{-C}_6\text{H}_4(\text{NH}_2)_2$. An orange-red *azo dye* (e), the 1st ever made in the (a) series, is being further investigated. It seems to have the formula $\text{PhN}:\text{NC}_6\text{H}_2\text{N}(\text{NH}_2)_2$, the positions of the substituents being the same as in chrysoidine. By reduction (e) is expected to yield $\alpha, \alpha', \beta\text{-C}_6\text{H}_2\text{N}(\text{NH}_2)_3$. The NH_2 derivs. of (a) obtained by the new method usually are accompanied by other products which are being examd. In the case of (b) 1 of such by-products seems to be (d), while another possibly is $\gamma\text{-C}_6\text{H}_4\text{NNH}_2$. With quinoline, NaNH_2 gave $\alpha\text{-C}_6\text{H}_4\text{NNH}_2$ (yield, 25%), together with a fraction $b_{30} 250^\circ$ (to be examd. later). If 2 mols. of (a) for 1 of NaNH_2 be taken and the reaction temp. be higher, $\alpha, \alpha\text{-dipyridylamine}$, $(\text{C}_5\text{H}_4\text{N})_2\text{NH}$, doubtless is produced, but the expts. on its prepn. by this method are not yet completed. It was obtained by the interaction of $\alpha\text{-C}_6\text{H}_4\text{NCl}$ with (b) in presence of ZnCl_2 (yield, 25%), very long, colorless needles, m. $86-7^\circ$; its soln. in concd. H_2SO_4 is not colored by HNO_3 . Expts. were also made on the simultaneous action of NaNH_2 and MeI on α -picoline, with the expectation that the latter would at first yield the methiodide, $\text{MeC}_6\text{H}_4\text{NMeI}$, which by interaction with NaNH_2 would give $\text{MeC}_6\text{H}_4\text{NMeNH}_2$, and that this compd. by rearrangement would change to $\text{NH}_2\text{CH.CH:CH.CH:CMe.NMe}$. The results,

however, showed that instead of the latter *dimethylaminopicoline*, $\alpha, \alpha' \text{-C}_6\text{H}_2\text{NMe}(\text{NMe}_2)$ (f) is produced; colorless liquid of a feeble (a)-like odor, b. $198-200^\circ$; *chloroplatinate*, $\text{C}_6\text{H}_{12}\text{N}_2\text{HCl.PtCl}_4$; glittering orange-colored crystals, m. 190° (decompn.); *picrate*, $\text{C}_6\text{H}_{12}\text{N}_2\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$, yellow prisms, m. 153° . In the formation of (f) by this method the mother liquor contains, besides unchanged picoline, varying amts. of (c), obtained as the *chloroplatinate*, $(\text{C}_6\text{H}_4\text{N}_2\text{HCl})_2\text{PtCl}_4$, orange-red crystals, m. 185° , and of *monomethylaminopicoline*, also obtained as the *chloroplatinate*, $(\text{C}_7\text{H}_{10}\text{N}_2\text{HCl})_2\text{PtCl}_4$, bright red prisms, m. $178-9^\circ$. (f) was also prepd. by direct methylation of (c) by means of MeI and MgO . (a) also reacts with $\text{MeI} + \text{NaNH}_2$, giving *dimethylaminopyridine*, isolated as the *picrate*, $\text{C}_7\text{H}_{10}\text{N}_2\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$, m. 182° , and *monomethylaminopyridine*, also isolated as the *picrate*, $\text{C}_6\text{H}_8\text{N}_2\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$, m. 190° .

H. M. GORDIN.

Nitration of α -aminopyridine. A. E. CHICHIBABIN. *J. Russ. Phys. Chem. Soc.* 46, 1236-44 (1914).—Unlike $\text{C}_5\text{H}_4\text{N}$ itself, its NH_2 derivs. are readily nitrated. Thus $\alpha\text{-C}_5\text{H}_4\text{NNH}_2$ gave with HNO_3 a mixt. of α, β' -aminonitropyridine (a), yellow leaflets, m. 188° , and what seemed to be α, β -aminonitropyridine (b), yellow needles, m. 162° , the former predominating. In dil. H_2SO_4 (a) reacts with HNO_3 with elimination of N and formation of α -hydroxy- β' -nitropyridine, $\text{C}_5\text{H}_4\text{O}_2\text{N}_2$, yellowish needles, m. 184° , sol. in strong acids, but is reprecip. by the addition of much H_2O , also sol. in dil. alkali in the form of a *phenolate* which is salted out by concd. alkali in the form of needles; from its soln. in dil. alkali dil. acids ppt. the free base, showing it to be an OH compd., and not a pyridone. In the presence of concd. HCl (a) is converted by HNO_3 into α -chloro- β' -nitropyridine, m. $108-9^\circ$, has a feeble odor at ordinary temp., but when warmed with H_2O it develops a strong odor of $\beta\text{-C}_5\text{H}_4\text{NNO}_2$; sol. in concd. acids only. Upon reduction (a) gave $\alpha, \beta' \text{-C}_5\text{H}_4\text{N}(\text{NO}_2)_2$ (Meyer and Staffen, C. A. 7, 1878). According to these authors, this compd. possesses none of the properties of $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$. This is not quite so. While in the cold it does not react with $\text{FeCl}_3 + \text{H}_2\text{S}$, it does so in hot dil. HCl , giving dark blue flakes which turn green by treatment with concd. HCl . Unlike (a), (b) is volatile with steam, and partly volatilizes even upon drying at 100° . It is sol. in concd. acids, giving colorless solns. which turn yellow upon diln. with H_2O , probably on account of hydrolysis.

H. M. GORDIN.

Oxidation of the methyl groups of open-chain unsaturated-compounds. B. K. MEREZHKOVSKII. *J. Russ. Phys. Chem. Soc.* 46, 1244-50(1914).—Continuing his former work (*C. A.* 9, 799), M. detd. the influence of the concn. of KMnO_4 on the oxidation of the Me groups of unsatd. open-chain compds., using propylene, isobutylene and $\text{Me}_2\text{C}:\text{CHMe}$. The concn. of the KMnO_4 varied between 0.5 and 7%, and the extent of oxidation was measured by the amt. of $(\text{CO}_2\text{H})_2$ produced along with other acids. The total amt. of acid was detd. alkalimetrically, while the $(\text{CO}_2\text{H})_2$ was detd. as $\text{Ca}(\text{CO}_2)_2$. The results, represented by a curve, were as follows: No trace of $(\text{CO}_2\text{H})_2$ is produced when the concn. of KMnO_4 is 0.5%. As the concn. rises to 3%, the amt. of $(\text{CO}_2\text{H})_2$ rises slowly, but when the concn. passes above 3%, the amt. of $(\text{CO}_2\text{H})_2$ increases very fast, reaching a max. at 7% KMnO_4 , when it constitutes 48% of the total acids, showing that at this concn. the velocity of oxidation of the Me groups equals the velocity of oxidation of the double union itself. Making similar expts. with propane, isobutane and trimethylethane, it was found that they are not affected by KMnO_4 in the above concns.

H. M. GORDIN.

Solubility of nitrophenolates in mixtures of alcohol and water. V. M. FISHER. *J. Russ. Phys. Chem. Soc.* 46, 1250-70(1914).—With a view to detg. the influence of nonelectrolytes on the solubility of salts in H_2O , the solubility of several salts at 25° in mixts. of H_2O and EtOH, MeOH or acetone, was detd. For mixts. of H_2O + EtOH the following salts were used: the picrates of Na, K and Ba, the Na salts of *p*- $\text{C}_6\text{H}_4(\text{NO}_2)\text{OH}$, 1,2,4- $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{OH}$ and 1,2,4- $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)\text{OH}$, and Ba dinitrosalicylate, while for mixts. of H_2O and MeOH or acetone K picrate and 1,2,4- $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{ONa}$ were used. The results, given in several tables and diagrams, were as follows: For H_2O + EtOH all of the above salts, and probably all nitrophenolates, have an isotherm with 1 max. and 2 minima of solubility. This peculiar fact is most probably due to the same cause which imparts color to salts of colorless nitrophenols, i. e., to a particular kind of isomerization (Hantzsch, *C. A.* 1, 997). This view is corroborated by detns. of the coeff. of extinction for solns. of the nitrophenolates in H_2O + EtOH, showing that the variation in the values of this coeff. also is not a linear function of the concn. of EtOH. Owing to lack of suitable app., these detns. were only approx., more exact data being promised for a future date. The viscosity of mixts. of H_2O + EtOH containing between 0-60% EtOH was found to be but very little influenced by the presence of Na picrate (2.358 g. in 100 cc. of soln.). Detns. were also made of the variation in the elec. cond. of solns. of this salt in H_2O + EtOH when the concn. of either alc. or salt was made to vary.

H. M. GORDIN.

Condensation of phenol with unsaturated ketones. Condensation of phenol with mesityl oxide. A. P. DIANIN. *J. Russ. Phys. Chem. Soc.* 46, 1310-9(1914).—In former work it was shown that satd. ketones react with PhOH in presence of HCl to form diatomic phenols: $\text{R}_2\text{CO} + 2\text{PhOH} = \text{R}_2\text{C}(\text{C}_6\text{H}_4\text{OH})_2 + \text{H}_2\text{O}$. With a view to examg. how the reaction would go with unsatd. ketones, mesityl oxide (a) and phorone were made to react with PhOH under the influence of HCl. The work on phorone will appear later. As to (a) its reaction with PhOH yields 2,4,4-trimethyl-2-hydroxy-phenyl-2,3-dihydrobenzopyrane, $\text{O.C}_6\text{H}_4.\text{CMe}_2.\text{CH}_2.\text{CMeC}_6\text{H}_4\text{OH}$ (b) (Bulow's numera-

tion, *Ber.* 34, 1190) (yield, 56%), needles, unites with solvent of crystn., e. g., $8\text{C}_{12}\text{H}_{20}\text{O}_2 \cdot \text{Et}_2\text{O}$ (m. 171-2°), $4\text{C}_{12}\text{H}_{20}\text{O}_2 \cdot \text{EtOH}$ (m. 163-4°), $4\text{C}_{12}\text{H}_{20}\text{O}_2 \cdot \text{Me}_2\text{CO}$, $4\text{C}_{12}\text{H}_{20}\text{O}_2 \cdot \text{AcOH}$, and $4\text{C}_{12}\text{H}_{20}\text{O}_2 \cdot \text{CHCl}_3$, sol. in hot concd. alkali, sepg. on cooling as a cryst. phenolate which upon recrystn. from H_2O gradually decomps. When (b), obtained by crystn. from Et_2O , is dissolved in hot alkali, the soln. boiled to the complete removal of Et_2O and then satd. with CO_2 , it seps. as a cryst. powder which, after drying at 140°, m. 157.5°. With BzCl (b) gives a benzoyl compound, $\text{C}_{13}\text{H}_{10}\text{BzO}_2$, m. 161°, sol. in concd.

H_2SO_4 with orange-red color. With $\text{MeI} + \text{KOH}$ in MeOH (b) gives a *methyl ether*, $\text{C}_{11}\text{H}_{11}\text{MeO}_2$, thick, colorless, oily liquid, $b_{760} 285-6^\circ$, $d_{15}^{20} 1.098$; odorless at ordinary temp., but on warming develops an odor of bitter almonds; is colored orange-red by concd. H_2SO_4 , is oxidized by $\text{CrO}_2\text{-AcOH}$ to anisic acid. The formation of the latter, in connection with the fact that when fused with alkali (b) gives salicylic acid, is taken as proof that the $\text{C}_6\text{H}_4\text{OH}$ in (b) is in the *p*- while the $\text{C}_6\text{H}_4\text{O}$ is in the *o*-position. When (b) is distd. it decomps. into PhOH and $2,4,4\text{-trimethylbenzopyrane}$, $\text{O.C}_6\text{H}_4.\text{CMe}_2.\text{CH}:\text{CMe}_2$

(c), colorless liquid of a peculiar odor, $b_{24} 166^\circ$, $b_{760} 235-6^\circ$ (slight decompn.), $d_{15}^{20} 1.0085$, $n_D^{20} 1.545$, is not affected by heating with concd. KOH to 130° , reacts with Br in CS_2 with evolution of HBr , slowly decolorizes dil. KMnO_4 , is colored orange-red by concd. H_2SO_4 . When (c) is mixed with PhOH and HCl is passed into the mixt., (b) is regenerated. In the prepn. of (b) it was accompanied by a small amt. of $\text{Me}_3\text{C}(\text{C}_6\text{H}_4\text{OH})_2$. The mechanism of the reaction of (a) with PhOH in presence of HCl is supposed to be as follows: $\text{Me}_3\text{C}:\text{CHAc} + 2\text{HCl} = \text{Me}_3\text{CClCH}_2\text{CMeClOH}$; $\text{Me}_3\text{C-ClCH}_2\text{CMeClOH} + 2\text{PhOH} = 2\text{HCl} + \text{Me}_3\text{C}(\text{C}_6\text{H}_4\text{OH})\text{CH}_2\text{CMe}(\text{OH})\text{C}_6\text{H}_4\text{OH}$. The latter by loss of H_2O changes to (b). H. M. GORDIN.

Action of carbon monoxide on magnesium-organic compounds. V. EGOROVA. *J. Russ. Phys. Chem. Soc.* 46, 1319-32 (1914).—Attempts to make tert. alcs. by the action of CO on Mg org. compds. (Vinay, *Diss.*, Geneva 1913) were not successful. By passing CO into Me_3CMgCl (a) the *hydroxy ketone*, $\text{Me}_3\text{CCH}(\text{OH})\text{COCMe}_3$ (b) was obtained, m. $80-2^\circ$, could not be converted into a semicarbazone. By means of Na in crude Et_2O (b) could not be reduced, but an excess of (a) in Et_2O reduced it to the *glycol*, $(\text{Me}_3\text{CCHOH})_2$, m. $125-7^\circ$, congeals $105-10^\circ$, the (a) decomp. into C_4H_8 and HMgCl , which acts as reducing agent. Upon oxidation with KMnO_4 (b) gave $\text{Me}_3\text{CCO}_2\text{H}$ and the *diketone*, $(\text{Me}_3\text{CCO})_2$, b. $170-2^\circ$. By the action of CO on iso-PrMgBr the hydrocarbon $\text{Me}_3\text{CHCH}:\text{CMe}_2$ and a *compound*, m. $113-4^\circ$, were produced. The latter is either the *aldehyde*, $\text{Me}_3\text{CHCOC}(\text{OH})(\text{C}_6\text{H}_7)\text{C}(\text{OH})(\text{C}_6\text{H}_7)\text{C}(\text{OH})(\text{C}_6\text{H}_7)\text{-CHO}$, or the corresponding *acid*, $\text{C}_{17}\text{H}_{34}\text{O}_8$, the analytical data being inconclusive. By the action of CO on $\text{Me}_3\text{EtCMgCl}$ nothing but Me_3EtCOH (c) could be obtained. After a discussion of several possible explanations of the last reaction, preference is given the assumption that, owing to the presence of CO , the O of the air takes part in it, with the intermediate formation of $\text{Me}_3\text{EtCOMgCl}$. This assumption gains support from the fact that when air is excluded by filling the reaction flask with CO_2 , the yield of (c) drops to insignificant proportions. H. M. GORDIN.

Action of tertiary amylmagnesium chloride on ethyl oxalate. E. VENUS. *J. Russ. Phys. Chem. Soc.* 46, 1332-6 (1914).—Egorova showed (*C. A.* 5, 1420) that the reaction between Me_3CMgCl and $(\text{CO}_2\text{Et})_2$ is one of reduction. It is shown by V. that $\text{Me}_3\text{EtCMgCl}$ (a) behaves in a similar manner, the products of its interaction with $(\text{CO}_2\text{Et})_2$ being the *ester*, $\text{C}_6\text{H}_{11}\text{CH}(\text{OH})\text{CO}_2\text{Et}$, b. $78-9^\circ$, $d_4^{20} 0.9668$, $d_{15}^{21} 0.9501$, $d_4^{21} 0.9462$, the *hydroxy acid*, $\text{C}_6\text{H}_{11}\text{CH}(\text{OH})\text{CO}_2\text{H}$, m. $72-3^\circ$, and the *ethoxy acid*, $\text{C}_6\text{H}_{11}\text{CH}(\text{OEt})\text{CO}_2\text{H}$, m. $107-8^\circ$. The reduction is ascribed to HMgCl which, together with C_6H_{10} , is produced by the decompn. of (a). The formation of C_6H_{10} in this reaction was proved by converting it into its bromide. H. M. GORDIN.

Structure of Gustavson's hydrocarbons obtained from pentaerythritol. O. FILIPOV. *J. Russ. Phys. Chem. Soc.* 46, 1141-99 (1914).—From an exhaustive exam. of the work done by himself and others on Gustavson's "vinyltrimethylene" (a) and its derivs., F. comes to the conclusion that (a) is a mixt. of $\text{CH}_3.\text{CMe}:\text{CH.CH}_2$ (b), b. 37.5° , and $\text{CH}_3.\text{C}(\text{:CH}_2).\text{CH}_2.\text{CH}_2$ (c), b. 42° , while the alc. obtained by G. from (a)

is $\text{CH}_3\text{C}(\text{OH})\text{Me}.\text{CH}_2\text{CH}_3$ (d). The $(\text{CH}_3\text{CO}_2\text{H})_2$ formed in the oxidation of (a) comes from (c) according to the following scheme: $(c) \rightarrow \text{CH}_3\text{C}(\text{OH})(\text{CH}_2\text{OH}).\text{CH}_2\text{CH}_3$

$(e) \rightarrow \text{CH}_3.\text{CO}.\text{CH}_2\text{CH}_3 \rightarrow (\text{CH}_3\text{CO}_2\text{H})_2$, while the simultaneously formed $\text{AcCH}_2\text{CH}_2\text{CO}_2\text{H}$ comes from (b): $(b) \rightarrow \text{CH}_3\text{C}(\text{OH})\text{Me}.\text{CH}(\text{OH}).\text{CH}_3 \rightarrow$

$\text{AcCH}_2\text{C}_2\text{CO}_2\text{H}$. As to the $\text{CH}_3(\text{CH}_2\text{CO}_2\text{H})_2$ which is also found among the oxidation products of (a), it owes its production to an isomerization of the 4-membered ring of (c) to a five-membered ring, the scheme being as follows: $(c) \rightarrow (e) \rightarrow \text{CH}_3\text{C}(\text{OH})(\text{CHO}).\text{CH}_2\text{CH}_3 \rightarrow \text{CH}_3.\text{CO}.\text{CH}(\text{OH}).\text{CH}_2\text{CH}_3$

$\rightarrow \text{CH}_3(\text{CH}_2\text{CO}_2\text{H})_2$. An attempt was made to prep. (d) synthetically by the action of Mg on $\text{AcCH}_2\text{CH}_2\text{CH}_2\text{I}$ (cf. Zelinskii and Moser, *Ber.* 35, 2648), in order to compare it with the (d) from (a), but the attempt failed. While the formation of the above acids in the oxidation of (a) may be accepted as proof of its consisting of (b) and (c), a better proof would be to compare these 2 hydrocarbons as obtained from (a) with the (b) and the (c), as well as with all other hydrocarbons of the formula C_6H_{10} , made synthetically. Owing, however, to difficulties of prepn., no attempts were made to carry out such syntheses. But since an equally satisfactory proof of the nature of (a) is obtainable by reducing it and comparing the product with all hydrocarbons of the formula C_6H_{10} , the work was carried into that direction. There are 3 cyclic compds., C_6H_{10} : cyclopentane (f), ethylcyclopropane (g), and methylcyclobutane (h). Of these (f) is known, and is entirely different from the reduction product of (a), while on synthesizing (g) and (h) and comparing them with this reduction product, it was found that the latter was identical with (h). Hence F.'s view of the comp. of (a) must be correct, since both (b) and (c) ought to give (h) by reduction. (g) was made from $\text{CH}_3\text{CH}_2\text{CHAc}$ (Lipp, *Ber.* 22, 1207) by acting on it

with $\text{N}_2\text{H}_4.\text{H}_2\text{O}$ and treating the resulting compd. with KOH (Kizhner's method). (g) $b_{715} 36.5-7^\circ$, $d_4^{20} 0.7055$, $d_4^{18.25} 0.6866$, $n_D^{18.25} 1.37973$. In synthesizing (h) the work of Perkin and Coleman (*J. Chem. Soc.* 53, 201) was repeated, substituting, however, $\text{C}_6\text{H}_5\text{Me}_2$ for PhMe. But the product was found to consist of a mixt. of $n\text{-C}_6\text{H}_{12}$, piperylene and $\text{PrCH}:\text{CH}_2$, with a probable admixt. of a very small amt. of (h). Equally unsuccessful was the attempt to prep. (h) by the action of Zn dust on $\text{CH}_3\text{BrCH}_2\text{CH}_2\text{CHBrMe}$ (L., *Ber.* 22, 2570), both in alc. and in acid soln., the product in the 1st case being $n\text{-C}_6\text{H}_{12}$, while in the 2nd case an indefinite mixt. (b. $30-70^\circ$) resulted. (h) was finally synthesized by K.'s method from cyclobutyl aldehyde (i) and $\text{N}_2\text{H}_4.\text{H}_2\text{O}$. As to (i) it was made by a complex series of reactions, starting with $\text{BrCH}_2\text{CH}_2\text{CH}_2\text{Cl}$ and $\text{Na}_2\text{C}(\text{CO}_2\text{Et})_2$. (h) $b_{715} 36-6.5^\circ$, smells like CHCl_3 , $d_4^{20} 0.7118$, $d_4^{18} 0.695$, $n_D^{18} 1.38473$, gives $\text{iso-C}_6\text{H}_{12}$ when hydrogenated at 205° in presence of reduced Ni. Another proof that (a) is not a $(\text{CH}_2)_6$ deriv. is the fact that when its reduction product is passed, even very slowly, over Al_2O_3 at 326° , it still remains satd., since $(\text{CH}_2)_6$ derivs. under these conditions are converted into unsatd. open chain compds. (Ipat'ev, *J. Russ. Phys. Chem. Soc.* 35, 603). While (a) upon reduction gives (h) exclusively, showing that in this case both (b) and (c) are hydrogenated simultaneously, it is different when each of them is hydrogenated separately in presence of Pd, (c) under these conditions changing to (h), while (b) is converted into $\text{iso-C}_6\text{H}_{12}$, showing that, at least in the presence of Pd, (b) is less readily hydrogenated than (c), and that the excess of H converts the former into an open-chain compd. In accord with F.'s view of the comp. of (a), G.'s dibromide obtained from (a) is $\text{CH}_3\text{CBr}(\text{CH}_2\text{Br}).\text{CH}_2\text{CH}_3$. This,

when treated with PbO, gives (i) which, under certain conditions, isomerizes to cyclopentanone. The mechanism of the formation of (a) from $C(CH_2Br)_4$ (j) consists in

the production of spiropentane, $\begin{array}{c} CH_2 \\ | \\ CH_2 - C - CH_2 \\ | \\ CH_2 \end{array}$, as intermediary product. This isom-

erizes to (c), which then partly changes to (b). The isomerization of (c) to (b) is facilitated by EtOH, since this isomerization may be brought about by heating (c) with $ZnBr_2$ and $ZnBrOH$ in the presence of a considerable amt. of dil. alc., while if in the prepn. of (a) from (j) only a trace of EtOH be used, the product consists almost exclusively of (c). The isomerization of (c) to (b) is best accomplished by passing the former over asbestos covered with Al_2O_3 at 300° . A conversion of (c) into an unsatd. open-chain compd. does not take place in this reaction, at least not at this temp.

H. M. GORDIN.

Constitution of allantoin and allied substances. HENRY D. DAKIN. Herter Lab., New York. *J. Chem. Soc.* 107, 434-9(1915).—The explanation of Mendel and D. (*C. A.* 4, 2309) that the optical inactivity of allantoin is due to keto-enol tautomerism is defended against Titherley's criticisms (*C. A.* 7, 3486). The optical instability of other hydantoins in which this change is possible confirms this view. Attempts to resolve 3-methylallantoin (A) and homoallantoin (B) by feeding to rabbits, by the use of actively fermenting yeast, and with the aid of bacteria and molds, failed. (A) gives no ppt. with Wiechowsky's reagent ($Hg(OAc)_2$ and $NaOAc$), while (B), which contains no substituent in position 3, gives a ppt. *d*-Alanine and $KCNO$ in H_2O on the H_2O bath for 1 hr. gave *l*- α -carbamidopropionic acid, $MeCH(NHCO_2NH_2)CO_2H$, prisms, sinters 195° m. $198-200^\circ$, $[\alpha]_D^{20} -9.5^\circ$ in H_2O ; 3 g., boiled 2 hrs. with 50 cc. H_2O and 9 cc. concd. HCl , gave *l*-methylhydantoin, $MeCH.NH.CO.NH.CO$, crys-

tals, m. $175-7^\circ$. Its $[\alpha]_D^{20}$ was 50.6° in H_2O , probably a minimum value, owing to possible racemization. This takes place rapidly in alk. soln. *dl*- $MeCH(NHCONH_2)CO_2H$ sinters 182° and m. 185° , not 155° , as given in the literature. Similarly, *dl*- α -methylhydantoin m. 150° , not 125° or 140° .

M. HEIDELBERGER.

Phototropy and thermotropy. VI. Polymorphic vanillylidenearylamines produced by trituration and by the influence of actinic light. ALFRED SENIER AND ROBERT B. FORSTER. Galway. *J. Chem. Soc.* 107, 452-9(1915); cf. *C. A.* 8, 3781; 9, 202. —(th = thermotropic, lt = higher limit of thermotropy, tl = thermotropic at the temp. of solid CO_2 , tlt = thermotropic between room temp. and the temp. of solid CO_2). Triboluminescence and phototropy were not observed, although deeper colored polymorphic forms were obtained by 3 or 4 months' exposure to sunlight. The deepening of the color on exposure to sunlight in the case of the polymorphic varieties obtained by titrituration (r) was usually more pronounced than in the case of the original substances. The apparently permanent polymorphic forms, in general more deeply colored than the original substances, obtained by exposure to sunlight, are denoted by s. All m. ps. are cor. *Vanillylidene derivatives of:* Aniline, m. 157° , not $152-3^\circ$ (Ott, *Monatsh.* 26, 335(1905)), tl, lt, 150° , no r, s. *o*-Toluidine, th $20-90^\circ$, no r, s. *m*-Compd., tl, lt 80° (cf. S. and Shephard, *C. A.* 4, 1025); r, changes back after 1 week in the dark, tl, lt 25° ; s. *p*-Compd., m. $119-20^\circ$, not 117° (Manchot and Furlong, *C. A.* 4, 459), tl, lt 100° ; r, reverts at about 50° ; s. *o*-4-Xylidine, faintly yellow needles, m. $112-3^\circ$, tl, lt 100° , changes on cooling to a darker form, instead of, as is usual, to a lighter form; r, tl, reverts 100° ; s. *m*-4-Xylidine, plates, m. 109° , tlt, also darkens when cooled; s; no r. *p*-Xylidine, faintly yellow needles, m. 103° , tl, lt 100° ; r, reverts 90° . *ψ*-Cumidine, very pale yellow needles, m. $123-4^\circ$, tl, lt 110° ; s; r, tlt, reverts at about 70° . *p*-Chloroaniline, almost colorless prisms, m. $128-9^\circ$, tl, lt 125° ; r, tlt, reverts at about

60°; s. *m*-Bromoaniline, brownish yellow, m. 75°; r, softens 67°, m. 70°; both are th between 20 and 65°; s. *p*-Bromoaniline, pale yellow needles, m. 123-4°, th 20-120°; r, reverts 60°; s. *p*-Aminophenol, chocolate plates, decomp. above 170°, m. 201-2°. *m*-Anisidine, deep yellow prisms, m. 118-9°, tl, lt 117°; r, reverts at about 60°; s. *p*-Anisidine, nearly colorless needles, m. 132°, tl, lt 130°; r, tlt, reverts at about 60°; s. *o*-Aminobenzoic acid, tl, lt 160°, no r or s. *m*-Aminobenzoic acid, yellow and orange crystals, gradually changing to the orange form; solns. in acetone and MeOH are deep red, apparently very sensitive to polymorphic change. *p*-Aminobenzoic acid, yellow and orange-red crystals (cf. M. and F., *loc. cit.*), the latter being changed by the slightest friction to the yellow form, which decomp. above 200° and m. 213-4°; r, tlt; s. *Benzidine*, gamboge-colored crystals, decomp. above 150°, m. 184-6°, tlt; r, tl, lt 170°, the color being deepest at room temp.; s. α -Naphthylamine, pale yellow needles, m. 113-4°, tl, lt 110°; r, tlt, reverts at about 60°; s. β -Naphthylamine, biscuit-colored needles, m. 148-9°, th from 20-135°; r, reverts at about 90°; s. M. H.

Organic derivatives of silicon. XXIII. Further experiments on the so-called siliconic acids. JOHN A. MEADS and FREDERIC S. KIPPING. Nottingham. *J. Chem. Soc.* 107, 459-68 (1915); cf. *C. A.* 8, 1956.—The generality of the conclusions developed in the previous paper is demonstrated by the results now reported. Decompn. of $\text{PhCH}_2\text{SiCl}_3$ with ice-cold H_2O produces very little of the insol. glue-like condensation products unless the soln. is kept for several hrs. Extn. with Et_2O and manipulation of the product as in the case of the mixt. obtained from PhSiCl_3 gave a colorless, flaky resin, m. 40-50°; systematic fractional pptn. of this from Et_2O by means of light petroleum gave a series of amorphous products ranging from a sol. fraction of low mol. wt., differing little in compn. from $\text{PhCH}_2\text{Si}(\text{OH})_3$, to an insol. partial anhydride of high mol. wt. The principal components were, apparently, compds. produced from 3, 4 and 5 mols. of $\text{PhCH}_2\text{Si}(\text{OH})_3$. Ppts. of "benzylsiliconic acid" obtained from alk. soln. melt somewhat higher than those obtained above and corresponded more closely to the glue-like preps. of the preceding paper. Decompn. of $\text{PhCH}_2\text{SiCl}_3$ with steam gave a hard, brittle solid, m. about 60-70°, sol. in the org. solvents, probably essentially a mixt. of the final condensation products of the trihydroxide. Sodium benzylsiliconate, probably $\text{PhCH}_2\text{SiO}_2\text{Na}$, crystals, from any of the "acid" preps. and alc. NaOMe evapd. over H_2SO_4 and KOH; readily sol. in cold H_2O . About 0.5 of the pasty product obtained by passing vapors of PrSiCl_3 into ice- H_2O was sol. in Et_2O ; evapn. of this gave a glue-like mass which rapidly lost its solubility. The insol. portions appear to be $(\text{PrSiO})_2\text{O}$ (cf. Melzer's "propylsiliconic acid," *C. A.* 3, 176). When alk. solns. of the Pr compd. were acidified or satd. with CO_2 an insol. oil pptd. after some time, immediately if NH_4Cl was used as the pptg. agent. Sodium propylsiliconate, prepd. like the benzyl compd., needles or prisms, sol. in H_2O . M. HEIDELBERGER.

Derivatives of a new form of glucose. JAMES C. IRVINE, ALEXANDER W. FIFE and THOMAS P. HOGG. Univ. St. Andrews. *J. Chem. Soc.* 107, 524-41 (1915).—The γ -methylglucoside (A) used was prepd. according to Fischer (*C. A.* 8, 3036), care being taken to use acetone-free reagents. For the methylation expts. it was found unnecessary to distil (A) before use. 12 g. (A) were treated 4 times by the usual $\text{MeI-Ag}_2\text{O}$ process, yielding, after repeated fractionation controlled by n detns., tetramethyl- γ -methylglucoside (B), $\text{C}_{11}\text{H}_{22}\text{O}_6$, mobile liquid, b_{D}^{20} 106°, readily sol. in H_2O and org. solvents, non-reducing, very easily hydrolyzed, instantly reduces alk. KMnO_4 in the cold, n_{D}^{20} 1.4458, d_4^{15} 1.1064, $[\alpha]_{\text{D}}^{20}$ -14.6° in H_2O . A table is given contrasting these properties with those of the α - and β -compds. A 5% soln. of (B) hydrolyzed slowly in 0.01 N HCl at 40°, more quickly at 100°, the $[\alpha]_{\text{D}}$ passing through a max. (negative). The acid concn. was finally raised to 0.1 N and the heating continued until the $[\alpha]_{\text{D}}$ remained const. at -5.4°. For rapid work, 0.1 N acid may be used from the start.

The resulting *tetramethyl-γ-glucose* (C) resembles glycerol, $b_{0.08}$ 122°, n_D 1.4585, d_4^{15} 1.1644, $[\alpha]_D^{20}$ -19.7° in MeOH, in H₂O, initial, -3.85°; final, -7.21°; resembles (B) with solvents and KMnO₄, reduces Fehling soln. on warming, reacts in boiling H₂O with PhNHNH₂ and HOAc, giving a dark oil which could not be purified, but which seemed to be a hydrazone rather than an osazone. (C) does not react with PhNH₂; with MeOH containing 0.25% HCl it rapidly yields (B), the $[\alpha]_D$ changing from - to + and back again. 2 g. (C) in 200 cc. H₂O was treated with 16 cc. 2 N NaOH and then gradually, with shaking, with 56 cc. KMnO₄ (1 cc. = 0.01575 g. KMnO₄). CO₂ was passed through the mixt., which was filtered and evapd. dry *in vacuo*. Extn. with Et₂O gave 0.6 g. neutral, mobile liquid, possibly a *tetramethylpentitol*. The Et₂O-insol. residue was acidified with HCl and extd. with Et₂O in Hagemann's app., yielding 1.4 g. of a *tetramethylgluconolactone*, C₁₀H₁₈O₆, initial $[\alpha]_D$ in aq. alc., 59°, after 4 hrs., 46°. Reduction of (C) according to I. and Paterson (C. A. 8, 2341), except that the Et₂O soln. of the sugar was very dil. and 2.5% Na-Hg was used, gave, after 2 reductions, a *tetramethylsorbitol*, $b_{0.4}$ 125°, n_D 1.4568, $[\alpha]_D$ -6.2° in H₂O; a soln. in 0.5 N H₂BO₃ showed optical changes which are taken to indicate the presence of 2 adjacent OH groups (Böseken, C. A. 8, 95), which would point to the formula MeOCH₂CH-(OMe)CH(OMe)CH(OMe)CH(OH)CH₂OH. (B) condenses readily with acetone in the absence of catalysts; in order to convert the resulting compd. into a volatile deriv. it was methylated by the MeI-Ag₂O method, but underwent simultaneous oxidation. The portion volatile under 0.05 mm. was remethylated and refractionated until sepd. into (1) *trimethyloxy-γ-methylglucoside monoacetone* (D), C₁₂H₂₄O₇, $b_{0.08}$ 105-6°, n_D 1.4493, d_4^{15} 1.1133, consists of at least 2 isomers, as shown by the differing $[\alpha]_D$ (-3.4° and 0° in MeOH) when refractionated into 2 equal parts; and (2) a disaccharide deriv., *anhydrobisdimethyloxy-γ-methylglucoside monoacetone*, viscous syrup, $b_{1.4}$ 200°, n_D 1.4587. Hydrolysis of (D) in 0.1 N HCl at 90° for 50 min. gave a const. $[\alpha]_D$ of 41°, yielding a *trimethyloxy-γ-methylglucoside*. In an extended discussion it is concluded tentatively that (C) is best represented by (I), although the formation of

the unimol. lactone is hard to reconcile with this view. The formation of the above oxy derivs. is explained according to the scheme (II) $\rightarrow$ (III), with anhydride formation between the tertiary OH groups in the case of part of the oxidized γ -methylglucoside monoacetone and subsequent methylation of the anhydride and the unchanged oxy compd.

M. HEIDELBERGER.

Synthesis of gluco-*m*-hydroxycoumarin and glucoprotocatechuic acid. F. MAUTHNER. Budapest. *J. prakt. Chem.* 91, 174-9(1915).—In view of the widely extended occurrence of glucosides of hydroxycoumarin and of phenolcarboxylic acids in various plants, M. has synthesized representatives of both classes for study and comparison; *tetraacetylgluco-*m*-hydroxycoumarin* (a) was obtained in 60% yield by adding 7.5 g. acetobromoglucose in 10 cc. acetone to 3 g. *m*-hydroxycoumarin + 0.7 g. NaOH in 10 cc. cold H₂O and allowing the mixt. to stand for 5 hrs., with occasional addition of a few cc. of acetone to keep the liquid homogeneous; needles from MeOH, m. 177-8°. A 70% yield of *gluco-*m*-hydroxycoumarin* was obtained by shaking (a) for 16 hrs. with 6% Ba(OH)₂, needles from absolute alc., sinter 200°, m. 219-20°. It has a bitter taste,

and is sol. in cold 10% NaOH. *Methyl tetraacetylglucoprotocatechuic acid*, prepd. similarly to (a), m. 167–8°, needles from MeOH. On standing for 23 hrs. at 37.5° with Ba(OH)₂ it is converted into *glucoprotocatechuic acid*, hygroscopic needles from AcOEt, m. 81–2°. It gives a yellow color with FeCl₃, has a sour taste, does not reduce Fehling soln. and is easily hydrolyzed by dil. acids.

D. BRESE JONES.

Synthesis of the depside of gentisinic acid. F. MAUTHNER. Budapest. *J. prakt. Chem.* 91, 179–89 (1915).—3,6-(MeO)₂C₆H₂COCl (a), previously described as an oil (cf. C. A. 7, 2544), was obtained as crystals from petr. ether, m. 53–4°. On standing 0.5 hr. with an excess of NH₄OH it gave 3,6-dimethoxybenzamide, leaves from C₆H₆ + petr. ether, m. 141–2°: *benzanilide derivative*, from (a) and PhNH₂ in Et₂O for 2 hrs., needles from ligroin, m. 98–9°; 3,6-dimethoxybenzoyl-*p*-hydroxybenzoic acid (b), by vigorously shaking at –10° a mixt. of 3.5 g. of (a) in 20 cc. acetone with 2.2 g. *p*-HOC₆H₄CO₂H, 1.8 g. NaOH, 20 cc. H₂O and 10 cc. acetone, needles from dil. acetone, m. 161–2°; *methyl ester*, from (a) and *p*-HOC₆H₄CO₂Me, needles from MeOH, m. 72–3°; 3,6-dimethoxybenzoylvanillic acid, from (a) and vanillic acid, needles from dil. acetone, m. 176–7°; *methyl ester*, from (a) and Me vanillate, needles from MeOH, m. 113–4°; *m*-benzoic acid derivative, needles from dil. acetone, m. 140–1°; *methyl ester*, needles from MeOH, m. 81–2°; 2,3-hydroxynaphthoic acid derivative, needles from C₆H₆, m. 185–6°; *methyl ester*, needles, m. 150–1°; *monomethylgentisinic acid derivative*, needles from acetone, m. 131–2°; *syringic acid derivative*, crystals from dil. acetone, m. 173–4°; 3,6-dimethoxybenzoyl-*p*-hydroxybenzoyl chloride (c), from (b) and PCl₅, pptd. from CCl₄ with ligroin, m. 107–8°. *Penta*-[3,6-dimethoxybenzoyl-*p*-hydroxybenzoyl]glucose, prepd. by shaking for 50 hrs. a mixt. of 21 g. of (c), 25 cc. dry CHCl₃, 2.1 g. α -glucose and 8.1 g. quinoline, and pouring the resulting product into 700 cc. cold MeOH, m. 92–3°, d₄¹⁵ 1.5914, α_D^{19} 24.09.

D. BRESE JONES.

2,4-Dinitrophenylglycine. EDM. WALDMANN. Vienna. *J. prakt. Chem.* 91, 190–202 (1915).—The 70% yield of 2,4-(NO₂)₂C₆H₃NHCH₂CO₂H (a) obtained by Sanna (*Chem. Zentr.* 1904, 1393) and Abderhalden and Blumberg (C. A. 4, 3066) can be increased 15% by using the components in the following proportions: 54 g. (NO₂)₂-C₆H₃Cl in 400 cc. alc. heated for 2 hrs. with 20 g. H₂NCH₂CO₂H and 48 g. NaHCO₃ in 200 cc. H₂O. By reducing (a) in alk. media, reddish brown, amorphous substances are formed. In acid media, both NO₂ groups are simultaneously reduced, forming well defined cryst. compds. 2,4-Diazoxyphenylglycine was prepd. by reducing (a) in alc. with SnCl₄ + HCl; yellowish brown, lustrous leaves, becoming red 217°, decomp. on further heating. *Ethyl ester*, similarly prepd., red leaves. By reducing (a) with Sn and concd. HCl, 7-aminohydroxydihydroquinoxaline hydrochloride (b) was obtained in 80% yield, white needles, m. above 300° (decompn.). Warmed with AcONa in H₂O, it gives the *free base*, yellow needles + 2H₂O, m. 181°. On standing it becomes green. It has acidic reaction, and forms salts with acids and bases, reduces Fehling soln. with formation of a brownish yellow ppt. *Stannic chloride salt*, C₈H₆N₂O₂·2HCl·SnCl₄, long needles having an acid reaction. *Sulfate*, C₈H₆N₂O₂·H₂SO₄, rose needles. By recrystg. from H₂O it loses H₂SO₄ with formation of the salt (C₈H₆N₂O₂)₂H₂SO₄, small red leaves; *oxalate*, red leaves, m. 219°; *ferrocyanide*, (C₈H₆N₂O₂)₃·H₄Fe(CN)₆, white leaves which become green on standing; *potassium salt*; *sodium salt*, small yellow leaves, hydrolyzed by H₂O, forming a yellow cryst. ppt.; *triacetyl derivative*, insol., yellowish white ppt. On diazotizing (b) yielded 2,7-dihydroxydihydro-

quinoxaline,  in 65% yield, reddish brown, flocculent ppt. It

gives a reddish yellow soln. with NaOH, from which it is not reprecipitated on addition of acids; with hot or concd. HCl it gives a reddish violet soln., from which it can be re-

pptd. by cooling or addition of H_2O . On oxidation with $\text{K}_3\text{Fe}(\text{CN})_6$, (b) gave a red compound, sol. in alkalis but insol. in acids. With Ba, Mg, Hg or Ag salts it forms reddish brown flakes. Oxidized with FeCl_3 , (b) gave 7-aminodihydroxydihydroquin-oxaline hydrochloride, brown, cryst. powder. The dibromo derivative, $\text{C}_6\text{H}_4\text{N}_2\text{OBr}_2$, was obtained from (b) and $\text{Br}\cdot\text{H}_2\text{O}$, yellow ppt., sol. in both acids and alkalis.

D. BREESE JONES.

Action of 1,2,4-chlorodinitrobenzene on *p*- and *m*-aminobenzoic acids. B. LINKE. Vienna. *J. prakt. Chem.* 91, 202-12 (1915).—2,4-Dinitrodiphenylamine-4'-carboxylic acid (a), prepared by warming on a H_2O bath for 6-8 hrs. a mixt. of 41 g. $\text{ClC}_6\text{H}_3(\text{NO}_2)_2$, 28 g. $p\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and 11 g. CaCO_3 in 50% alc., dissolving the reaction product in NaOH and pptg. with AcOH, decomps. on rapid heating, but when slowly heated is unaffected at 225° , yellow powder from AcOH + PhOH, insol. in most org. solvents, but forms an orange soln. with concd. H_2SO_4 ; sodium salt, vermillion crust; methyl ester, by warming (a) with MeOH and H_2SO_4 , microscopic orange needles from MeOH, becomes red 75° , and bright yellow at 178° ; ethyl ester, yellowish red needles from EtOH. On reduction with Na_2S , (a) gave 2,4-nitroaminodiphenylamine-4'-carboxylic acid, reddish brown powder, decomps. 225° ; with cold, concd. H_2SO_4 it gives a dark brown coloration, which with H_2O becomes yellowish brown. With concd. NaOH a cherry soln. is formed, but it shows no reaction with FeCl_3 ; hydrochloride, yellowish brown powder, decomps. 195° . Sn or SnCl_2 with HCl converts (a) into the diamino derivative, white powder which in the air changes to dark violet, decomps. 195° ; hydrochloride, thread-like needles from concd. HCl, decomps. $175\text{--}80^\circ$, unstable in the air, and reduces alk. AgNO_3 . With cold, concd. H_2SO_4 it gives a colorless soln., which becomes violet on diln. Diazotized and coupled with R salt or with FeCl_3 , it gives cherry solns. 2,4-Dinitrodiphenylamine-3'-carboxylic acid (b), prepd. similarly to (a), small, yellow needles, stable at 225° . It gives wine-colored solns. with cold, concd. H_2SO_4 , which yield yellow needles on diln.; sodium salt, orange needles + $2\text{H}_2\text{O}$; with salts of the alkali earths it gives yellow ppts.; methyl ester, orange needles from MeOH, m. 126° ; ethyl ester, yellow needles from EtOH, m. 105° . By reduction with Na_2S (b) yields the nitro-amino derivative, reddish brown powder, decomps. $215\text{--}18^\circ$; hydrochloride, reddish brown when moist, and dark green when dry, decomps. $175\text{--}80^\circ$. The corresponding diamino derivative was obtained by reducing (b) with Sn and HCl, very unstable in the air; hydrochloride, sandy, cryst. powder, decomps. $165\text{--}70^\circ$. It gives colored solns. with FeCl_3 , NaNO_2 , dil. mineral acids and with alkalis, and reduces alk. AgNO_3 .

D. BREESE JONES.

Addition products of nitric and picric acids with unsaturated organic compounds. G. REDDELIEN. Leipzig. *J. prakt. Chem.* 91, 213-44 (1915).—The formation of addition products of HNO_3 with α - and β -unsatd. ketones, which has been previously shown (cf. C. A. 7, 997), is attributed to the unsatd. O of the CO. R. has obtained the addition of HNO_3 to a large number of compds. having the unsatd. groups, CO, N:N, and C:N. Analogous addition compds. were obtained with picric acid, even with compds. having the C:C linkage. These compds. are easily decompd. by H_2O , leading to an equil.: $\text{BzH}\cdot\text{HNO}_3 + \text{H}_2\text{O} \rightleftharpoons \text{BzH} + \text{HNO}_3\cdot\text{H}_2\text{O}$. Unsatd. compds. having adjacent conjugate linkages, 1 of them being a CO or C:N, yield less stable addition compds. than do those having only 1 double linkage, but an adjacent C:C, on the other hand, greatly increases their stability. For those definite, intermediate addition products formed in reactions such as nitration and halogenation, R. proposes the name "Vorverbindungen." A review and discussion of the constitution of C_6H_3 is given, in which evidence for the C:C linkage is pointed out. The following addition products were prepd.: benzaldehyde nitrate, from BzH and HNO_3 (d. 1.371) at 0° , colorless oil at -30° , decomps. quickly in the air, becoming yellow and yielding
